APRICOTS.—Once more the time has arrived for affording some kind of protection to the Apricots. The trees are unusually well set with fruit buds, the only drawback being the forward state of these. Already some flowers are expanded, and a few genial days will bring the trees into full bloom. In addition to being the earliest among hardy fruits to expand their flowers they are also, unfortunately, nearly or quite the most delicate, very little frost sufficing to spoil the prospect of a good crop. Glazed copings and blinds of some kind running on rods suspended to the framework of coping, and reaching down to rings running on a wire strained to stakes about 30 inches from the wall, is by far the best system of protecting the trees. By a very simple device the blinds can be opened out or closed at will, and when cold frosty or easterly winds prevail it is mistake not to leave them open in the day time as well as during every cold night, the trees sustaining no injury from the slight shade caused, while it is very certain they are benefited by the protection afforded. A glass coping may well be set out not less than 30 inches from the wall, but if boards are substituted temporarily these ought not to be more than 12 inches wide. Frigi domo, cotton or canvas blinds, can be and often are used in connection with board copings with the best results. Failing either of the preceding conveniences some other protective measures must be devised, as it is rarely possible to secure a crop from unprotected trees. Where there are only a very few trees it ought not to be thought too much trouble to cover these with mats every night, these being removed as soon as the frost is off in the morning. Fish nets doubled or trebled and hung permanently over the trees will preserve the bloom from moderately severe frosts, and so also will branches of half dead Spruce Fir, these being nailed or otherwise firmly secured to poles fixed against the wall.

PEACHES AND NECTARINES.—These also are much too forward, those kept closely fixed to the walls especially so, but even the buds on most of the branches purposely loosened and allowed to swing clear of the walls are also showing colour, and will soon expand. This being so it is unwise to longer delay pruning and tying, or nailing as the case may be. There never was a greater promise of abundance of fruit on these trees, quite late formed and apparently unripe shoots being well furnished with large well formed flower buds. The appearance of the trees ought to plainly denote what should be cut out, it being very evident that the fruit of Peaches and Nectarines is borne principally on the young wood formed last season; this therefore must be reserved as much as possible consistent with thinly training, those badly placed, and all useless old and dead wood being cut cleanly out. In many instances it is advisable to cut some old wood with young shoots attached well back to strong young shoots; this, in addition to giving the latter more room, also serving to keep the centre of the tree properly furnished with good bearing wood. The young wood on trees under glass is usually shortened back to a good triple or wood bud, but this practice is not, as a rule, to be commended for open wall trees, both because appearances are deceptive, and also on account of leading growths being often lost. Lay in all that are sound and ripened to their full length, and rather more thickly than is advisable under glass, or say about 3 inches apart. Avoid bruising the trees in any way, and carefully remove all nails and shreds that are unduly pressing against or confining the growths, or otherwise their loss by gumming will be the inevitable result.

YOUNG PEACH TREES.—In many gardens Peach and Nectarine trees are rather short lived, and the prudent cultivator prepares for any

such contingency by preparing young trees to take their place. Not a few prefer to plant maidens or quite young unpruned trees, and these should at once be cut back to just below where they have branched strongly, or to within about 9 inches of the point of union with the stock. Under ordinarily favourable circumstances from four to six well placed shoots ought to be formed on trees thus pruned, these being at the spring pruning shortened back to a length of about 12 inches. Any of a similar size and age newly received from the nurseries to be similarly treated, and in either case sufficient branches ought to be obtained to lay the foundation of a good tree. What are known as trained trees, these having been twice cut back by either nurserymen or private growers, should be less freely pruned; in fact those already well established in a not over-rich border, will this season be fairly well furnished with fruit buds, and the weakest of the shoots ought to be reduced to about half their length, and the more vigorous left to two-thirds of their length, the cut being made to a well placed wood bud in each instance.

PROTECTING VARIOUS FRUIT TREES.—Peach and Nectarine trees, ought especially to be given some kind of protection while in flower, and Plums, Pears, and Cherries well repay for similar attention. The Peaches and Pears are the most forward, the latter being crowded with fine buds, many of which are bursting open. A moderately severe frost may in one night spoil the work of one, or it may be several seasons, and those responsible may regret when too late they did not contrive to fix some kind of protection over the trees. Not a yard of fish netting should be left where stored, and those who are prudent will have already laid in their stock of new netting. Scrim canvas is very cheap, and various shading and protecting materials are frequently advertised also at comparatively low rates. Poles or long iron rods are indispensable, as it is of the greatest importance that the netting or other material used should be firmly fixed well clear of the trees, or in windy weather it may easily do more harm than good. For all wall trees narrow coping boards are of good service, and if the long poles are arranged about 4 feet apart, firmly fixed to the boards, and let into the ground from 2 feet to 3 feet of the wall, the protecting material will as a rule be kept quite clear of the trees. It is by no means a difficult matter to protect even moderately large pyramid and bush trees, espaliers and cordons being more easily covered. The poles for the former may be made to meet over the centre, the covering somewhat resembling a bell-shaped tent, while that fixed over long thin trees may be more nearly after the model of a cloth when suspended over a hayrick.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced House.*—The fruit will soon have completed the first swelling and will enter on the stoning process. If the thinning has been carefully attended to there will be little more than the necessary quantity—namely, one fruit to every square foot of trellis covered by the trees. More Nectarines are usually left, which accounts for their being undersized as compared with Peaches. If there is more fruit than specified above, remove the smallest. There is no danger of the fruit falling during stoning, provided the wood was well ripened last season, and the trees are not unnecessarily taxed by too many fruits. During the stoning process keep the temperature as equable as possible, as a sudden check by draughts of cold air in the daytime and too high a temperature in the night may prove disastrous. The night temperature may range from 60° to 65°, but 5° less will be safer in severe weather, and in the daytime 70° to 75° with sun heat, and about 65° by artificial means when the atmosphere outside is cold and the sky overcast. See that the growing shoots are secured to the trellis as they advance, keeping those retained to attract the sap past the fruit stopped at the second or third joint. Syringe with water of the same temperature as the house to keep the trees free from red spider, and if aphids or thrips appear fumigate carefully when the foliage is dry. For destroying the insects named nothing is better than a solution of softsoap, 2 ozs. to the gallon of tepid water. Syringing is apt to cause deception as to the state of the border. The surface may be wet, whilst the soil beneath may be too dry; but give good supplies, and if the trees are weak apply diluted liquid manure in a tepid state.

Second Early Forced House.—Disbud gradually, removing the strongest and ill-placed shoots and have all the leading shoots tied down, taking care not to overcrowd them. Thin the fruits by degrees, and where it has set thickly extra attention will be required, removing those on the under side of the trellis or where badly placed, but leave those that are well exposed to light and air until they indicate by free swelling the necessity for further reduction, then remove the smallest. Syringe the trees early during fine days, and ventilate early during favourable weather. The temperature may range from 55° to 60° at night and 60° to 65° by day, ventilating at the latter temperature and closing the house when the heat is decreasing, allowing an advance of 5° to 10° from sun heat.

Trees Started Early in February.—The trees are now in flower or well advanced. As there are usually more flowers than are needed, all those on the under side of the shoots should be removed by drawing the hand the reverse way of the growths, and even yet there may be more than will be required for the crop, therefore it may be necessary to still further thin the blossom where most crowded, especially on the weaker shoots. Maintain the night temperature at 50° to 55°, and 55° by day with a little ventilation, as a close atmosphere is fatal to a good set. Ventilate freely above 55°, and allow an advance to 65° with sun heat. Fertilise the blossoms in the early part of fine days, either shaking the trellis or brushing the flowers with a camel's-hair brush when the pollen of the individual flower is ripe. Syringing must cease whilst the

trees are in flower, but the floor should be sprinkled morning and afternoon, avoiding cold currents of air.

Trees to Afford Ripe Fruit in Late July and August.—The house should be closed and the trees syringed two or three times a day until the buds show colour, when it must cease. The inside borders must be brought into a thoroughly moist state by repeated waterings if necessary, and with the border thoroughly drained liquid manure may be given to weakly trees and those having a superabundance of flower buds. Where there are many flower buds it will be well to ease the trees of those on the under side or at the back of the shoots as soon as they are sufficiently advanced, a gloved hand drawn the contrary way of the growth doing it expeditiously. Where the trees are weak the border may be mulched with a couple of inches of short, rather fresh manure, which will stimulate the roots into activity. Maintain a temperature of 50° by day and 40° to 45° at night, advancing to 65° with sun and full ventilation.

Late Houses.—If the lights are off there is no necessity to replace them until the flower buds have swelled to the point of showing colour. If they can be safely kept off until early or middle March all the better, it will then be early enough to have the trees in flower by the middle of April, and then they have the benefit of sun heat. Many late houses are unheated, which is a mistaken idea of economy, as the flowers are not safe from severe spring frosts even in May, and the fruit does not ripen perfectly if the late summer be cold and sunless. A gentle heat during the flowering period does much towards a good set, and in autumn artificial heat ripens the fruit and wood, continuing it if necessary for plumping the buds.

Unheated Houses or Wall Cases.—In these the chief consideration is the retarding of the blossoming. With moveable roof lights this is most effectively done, and being off, they need not be replaced until the flower buds are somewhat advanced and are beginning to show colour, after which it is not safe. Anything required in the way of pruning and securing to the trellis should be completed. Those that have not the lights removed may need supplies of water, so as to bring the soil into a thoroughly moist state, and may have the surface mulched a couple of inches thick with rather short fresh manure. Ventilate freely, so as to retard the flowering to as late a period as possible.

Where wall cases are employed for Apricots, let the lights remain off until the flower buds begin to show white, and after they are placed on ventilate freely, as nothing is so fatal to Apricot blossom as a close moist atmosphere. Plum cases may have the lights placed on by the middle of March, similar remarks applying to Cherries, also to Pears. Perhaps Plums are never so fine and luscious as when grown under glass. They come in a fortnight before those against an open wall, and Cherries not only come in earlier, but are finer and can be kept longer, as they can be protected from wet and birds.

FIGS.—Earliest Forced Trees in Pots.—Trees plunged in bottom heat will require water abundantly, applying it at the same temperature as the bed, or 70° to 75°, and alternating with liquid manure. Maintain the temperature at 60° to 65° at night, admitting a little air at 70°, but not so as to lower the temperature, closing at 75°, and if the temperature rises to 80° all the better. Thin the fruits, if too thick, as soon as the best placed and most promising can be decided upon for the crop. The thinning should be done some time before the last swelling commences.

Early Forced Planted-out Trees.—Those started at the new year are making a good growth, and should have the points of the shoots which issue from the base of the terminals pinched at the fifth or sixth leaf. Attend to tying the young shoots to the trellis as they advance, thinning where they are too crowded. Keep the night temperature at 55° to 60°. When it reaches 65° by artificial means in the day admit a little air, increasing the ventilation with the temperature, and reducing it in like manner, closing at 70°, syringing twice a day, and maintaining a genial atmosphere.

CHERRY HOUSE.—Ventilation must be attended to. A free circulation of air should pass through the house whenever the temperature exceeds 50°, the amount of air to be regulated by the conditions of the external atmosphere. Employ fire heat only to prevent the temperature falling below 50° in the day, and to maintain a night temperature of 40° to 45°. Attend to fertilising the flowers. Watch closely for the appearance of aphides, but it will not answer to fumigate whilst the trees are in blossom, nor will it be necessary provided they were perfectly clean previous to the flowers expanding. It may, however, be had recourse to so as the fruit is set. Grubs infest the trees generally; one kind of grub rolls itself up in the leaves, and can be eradicated by squeezing, but the other is the greater pest, and will be found encased on the under side of the leaves, giving them the appearance of being scalded. From the leaves it makes its way to the Cherries, perforating and destroying them. The only means of riddance is to examine the trees occasionally and destroy the grubs.

many stocks of bees which had greatly reduced their stores. February has been foggy throughout, with many frosty nights, the lowest temperature of the month being 22° Fahrenheit on the last day of it. With the exception of a fall of less than 2 inches we escaped the heavy falls of snow experienced elsewhere. Bees carried pollen on two days only, and on the 23rd many of them flew out freely. Some hives had more young bees than most of them had in June of last year. This augurs well for the future, but we shall have to depart from our usual custom of not feeding early and supply all with plenty of food. We trust none will put off this till it is too late, as owing to the recent low temperature blossoms affording honey will not come much earlier than the usual time.

STIMULATING BEES.

Feeding bees in dribblets during the spring months had its origin at a very remote period. I doubt not that it might be for the purpose of stimulation, as it was in my early years, but at the same time I think economy was the main factor that induced bee-keepers to use the hollow stems of plants or wooden scoops, hollowed by the same means as were our ancient canoes. It is no imagination to recall the poor workman earning no more than 7s. a week, with a wife and family to support, saving from his small earnings 1s. or 2s. to buy as many pounds of sugar to dole out in small quantities to his three or four hives to preserve the bees alive till April flowers afforded the pure nectar. Dismissing these hard times from our memory we come to the point, giving our experience of what caused us to abandon the system of feeding in dribblets.

The first year of my bee-keeping was an abundant Heather harvest, the old custom of driving the bees, taking all their honey, and then feeding them with syrup was greatly practised, as was also feeding in small quantities. The spring following found some of my hives still weighty with honey, while others were light, just in the right order for stimulating, which with the zeal of a youth and a beginner I carried out to the letter, expecting early swarms; but in every case I was defeated, the unfed ones everywhere taking the lead, and proved the most profitable, and I have witnessed nothing since to alter (to me, and I hope to all others) a now stereotyped opinion.

THE HIVING OF BEES

This was then as well understood as it is at the present day. Read as I may I cannot see that anywhere in the world the management of bees was studied and so well understood as in the west of Scotland. My first swarm hived on a bough of an Apple tree 6 feet from the ground, and unaided, and without a veil or any protection, I shook the bees into the hive, and quick as thought drew a cloth over them and inverted to the proper position. When guides of comb were placed in the hive the bees were caught on a sheet, and the hive placed over them. When hived in a thicket driving into an empty hive by the aid of smoke had to be resorted to. Carbolic acid is more efficient, speedier, and better in every way.

PUNIC BEES.

From what "A. H. B. K." has said at pages 184-5 it appears we do not in a great measure differ in our opinions. It is to him alone I am indebted for the Punic bees, and I was glad to read that they are not more liable than others to excessive propolisising. Many modern constructed hives favour this, which in addition to its disagreeable nature is an absolute waste of time, which the bee-keeper can to a great extent prevent. The Punic bees with me have gathered more pollen this spring than any other variety has done, and as to their hardy nature I can corroborate all "A. H. B. K." says about them. I have not observed more than fifty dead bees, both hives included, which is about the average of the whole of my hives. I observe the Carniolians almost free from mortality, the highest number of dead being three bees only. From the appearance of the Punic bees I am in high hopes they will prove themselves to be all that has been described. I have.

HINTS TO BEGINNERS.

THE SEASON.

JANUARY was a month of high winds, much rain, and a high temperature. It was favourable for feeding, and this has saved

given these, as well as some of my other stocks, pease brose made with honey, which they very soon appropriated. During the whole of my bee-keeping experience I never witnessed hives so healthy and strong as they are this season.

JUDGING HONEY.

On one occasion when acting as Judge the Secretary handed me a printed paper stating the points honey and honeycomb were to be judged by, a reproduction got up by some of the modern bee-keepers for the guidance of Judges! I read it, then asked the Secretary what was the use of sending for me to decide which was the best sample when I was to decide according to the opinions of others with perhaps less experience? A sharp eye and a keen taste enables one to decide in ten minutes which is the best sample, while following the paper might occupy as many hours. The Secretary overcame the difficulty by explaining "that the instructions were intended for exhibitors, not the Judges," and the work was done without the "paper."—A LANARKSHIRE BEE-KEEPER.

BEES CARRYING POLLEN.

WILL "Lanarkshire Bee-keeper" kindly answer the following questions through the Journal? Is it a sure sign when bees carry pollen now that they have a fertile queen? Where could I purchase a Lanarkshire hive, and what is the price? I wish to requeen my hives this summer, but have not sufficient time to make them in the way stated in the Journal.

Would you consider that the following plan might do fairly well? When the stock swarms take the queen from the swarm and the bees will go back to the stock; then we may expect her to swarm again in about nine days with a young queen and leave others in the stock, so that I would have young queens in both. How many hours would elapse before they would be fertile and laying?—A WORKING MAN.

[Bees carry pollen whether their queen is unfertilised or if they have none, but not with the same alacrity as they do when a fertile queen is present. A little experience soon enables one to distinguish the real state of the hive. One with a healthy and fertile queen carries larger pellets and more bees go to work than one the queen is not in a normal state.

LANARKSHIRE HIVE.

We cannot say where these can be had at present, and it is a proof that the B.K.A. standard size has been forced upon the public. Shallow frames have been recommended in combination with deep ones, which stultifies the arguments in favour of a standard frame, and precludes the possibility of interchanging all the frames.

REQUEENING HIVES.

It is advisable to requeen every hive annually, but not to kill the laying queen of a first swarm, at least not until you are prepared to introduce a youthful laying one. Let your hive swarm in the ordinary way, provided it is a full-sized swarm; if not so, use the means to have it so, as a first swarm cannot be profitable unless it is of good strength. After nine days divide into nuclei. This does not take much time, and can be performed in the evening.

WHEN EXPECTED TO LAY.

This depends upon the serenity of the weather and the age of the queen at the time of creeping from the cell. I have had a queen fertilised on the same day she was liberated from the cell, being actually from four to six days old, or from twenty to twenty-two from the deposition of the egg. More than once I have had them three months old before they were fertilised. I have had them commence to lay sixteen hours after fertilisation, and at other times months elapsed before they commenced. However, during the summer months in fine weather it is no unusual thing to have queens laying in four days after hatching, but it is more common for queens to begin their maternal duties in about a week from the time of leaving the cell, provided the weather is favourable.

P.S.—If a Lanarkshire hive cannot be made from the instructions which have appeared in the Journal, nor had from some maker, I might try to supply one of my own at about 11s.]

TRADE CATALOGUES RECEIVED.

Samuel Shepperson, Prospect House, Belper.—*List of Florists' Flowers.*

Richard Dean, Raneleigh Road, Ealing.—*Catalogue of Primroses and Hardy Plants.*

°° All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (A.B.).—We are bound to regard you as an inattentive reader, for exactly what you want to know is prominently stated on page 164, the very issue of the Journal to which you refer in your letter.

Primula verticillata (M.D.).—The plant we have received is admirably grown, and we are obliged by your note, which appears on page 198.

Calceolaria Lemon Queen (A.C.).—The writer of the article to which you refer says he has not seen the name of this variety in catalogues. It is only grown in a few gardens, but no doubt will soon make its way into nurseries, and thence to the general public.

Mohoe or Mohaut Tree (Inquirer).—Possibly this is the plant to which you refer; if so its botanical name is *Paritium elatum* or *Hibiscus elatus*, a native of the West Indies, and from the inner bark of which Cuba bast is formed. It will grow in a stove or intermediate house in a compost of loam and sand.

Calanthe Regnier (P.J.).—This *Calanthe* was introduced by M. Regnier of Paris, and flowers at the same time as *C. Turneri*—namely, later than *C. vestita*, and this renders it valuable where a long supply of flowers is wanted. It succeeds under the same treatment as the species above named, and you will find some cultural instructions on page 200 of this issue.

Dissolved Bones for Vines (G.S.H.).—It is not easy to give a definite answer to your query, as you have failed to indicate the condition of the Vines—top and root—as well as the kind of soil of which the border is composed. However, a dressing at the rate of 5 cwt. to an acre or 2 ozs. to the square yard at this late period of the season will be sufficient. This of course will be watered in. After growth has begun at root as well as shoot, or about the time the bunches reach the flowering stage, apply a similar dressing, and another before the berries take the second swelling. The addition of nitrate of soda or sulphate of ammonia in about half of the above proportion would be of advantage for the two earlier dressings. Another season you must use your own judgment as to whether a heavier dressing will be of advantage after seeing the effect this year. Double the quantity may be applied after the leaves have fallen and the borders are put in order for the winter. If the outside border is regularly watered the top-dressing may be applied in the same way to the inside border.

Landslip at Side of Carriage Drive (J.B.).—Drains to be efficient must tap the water at its source, and prevent its percolating down the embankment. These should be taken some little distance into the pan or solid part, so as to form a catch and hold for the water, and should be filled with rubble over the drains somewhat higher than the pan or hard bottom on which the loose soil rests, so as to prevent the water passing over the drains, and to take it down to them expeditiously. There should be a drain lengthwise of the slope about 4 feet from the top, and a corresponding one about 3 feet from the bottom, and between these should be cross drains about 15 feet apart, which should be taken into the pan and covered with rubble as before. These cross drains should be diagonal at about an angle of 45°, and communicate with the top and bottom drains, which should have suitable falls for the water, and have proper outlets. If the slipping is due to water from higher ground, then at the top of the cutting or a few feet below should be a rubble drain to catch the water as it comes down, and convey it away either by cross rubble drains to the bottom of the slope or independently according to local circumstances.

Tuberoses Planted Out (T.C.).—Years ago, and anterior to the "bedding period," the practice of establishing Tuberoses in pots and preparing the plants for planting in the open ground in June was common in some gardens, and we have seen very fine flowering groups of these plants. A few years ago we saw many plants growing in Messrs. Carter & Co.'s nurseries at Perry Hill, from bulbs placed in the ground in the same manner as Potatoes are planted. Several of the plants so grown flowered freely towards the end of summer, and others that produced spikes were potted in the autumn and flowered under glass in the winter. We see no reason, therefore, that you should not succeed by planting in a border under glass, provided the house is very

light, otherwise the distance from the root might militate against the sturdy growth of the plants. All we can say is that Tuberoses succeed well when planted out under favourable conditions. If you transfer the plants to the border the pots must stand in the house for some days previously, as it would not be wise to remove them direct from the hotbed to the soil.

Heating Range of Houses (*A Devonshire Subscriber*).—To heat your houses satisfactorily will require a boiler capable of heating 1500 feet of 4-inch pipes, it being always desirable to have too much rather than too little heating power, as when hard firing has to be resorted to there is a great waste of fuel. Four-inch pipes are best for all the structures. The connecting pipes need not necessarily be of the same size as those within the houses, but they ought not to be less than 2 inches. We prefer, however, to use 4-inch flow and return service pipes directly to the boiler, and branch to the different houses therefrom. When the structures are detached the pipes between the boiler and house should be covered with non-conducting material to prevent waste of heat. To maintain a temperature of 80° in the first compartment eight rows of 4-inch pipes would be required; in the second compartment, to maintain a temperature of 70° six rows would be needed, or four and four return pipes for the first, and three flows and three return pipes for the second, and to maintain a temperature of 50° in the other two compartments three rows or two flows and one return pipe would be necessary. To heat the conservatory the pipes should be doubled, as we presume they are in an open trench with iron grating over them in the pathway, but if exposed or above ground two flows and one return all round would give the heat desired. We have calculated for the houses to be heated to the temperatures named in the severest weather without having to drive the boiler or furnace unduly, but if you only require the first compartment as a stove then six rows of pipes will give you sufficient heat. If the second is to be an intermediate house four rows of pipes would do, and a flow and return would answer for the other if they are required to be kept at ordinary greenhouse temperature, and a flow and return around the conservatory would be sufficient to exclude frost, but it is always best to have too much rather than too little piping, as heat radiated at a moderate is better for the plants than when given off at a high temperature, besides being more economical. We have used 1½-inch pipes for connection between the boiler and houses satisfactorily, but they are apt to get choked with sediment, and when hard water is used "fur" up. When the boiler is kept free of sediment and the pipes duly flushed, the water used being soft, there is no objection to the employment of small pipes, but we do not advise less than 2-inch. The boilers have sockets according to their size, and rarely more than 4-inch, oftener being 3 inches than over, but that is immaterial, only for a powerful boiler the water should have free access to and out of it, and for the smallest boiler a 2-inch socket should be the minimum. Diminishing sockets on the pipes, or enlarging ones will be necessary of course to meet those of the boiler. A rise of 6 feet is not too much, as in your case the houses are on different levels, and will add to rather than interfere with the circulation. Ordinarily a rise in the pipes sufficient to prevent air lodging or cause it to rise to the highest point of each compartment where it can be got rid of by an air tap or air pipe is all that is required, or a rise of about half an inch in a 9 feet length of pipe. When houses are on different levels, indeed in all cases, it is well to have valves on both the flow and return pipe of each house.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. —(*A. A., Co. Down*).—*Hebeclinium ianthinum*, also known as *Eupatorium*. (*W. W.*).—1, *Ficus minima*; 2, *Asplenium cicutarium*. (*W. S.*).—The flower sent represents a distinct variety of *Dendrobium nobile*, the long-parted lip being suggestive of *D. Falconeri*. The position of the lip is also different from that in most varieties of *D. nobile*, and the flower is larger.

DAIRY COWS.

THERE is much in the various statements published about dairy farming that is calculated to puzzle and mislead an inquirer, who, seeing the sum total paid annually for importations of dairy produce, feels tempted to see if he cannot turn a few units of all those millions into his own pockets. If, like a prudent man, he first of all endeavours to count the cost of keeping a cow, and to ascertain what amount of profit is possible upon outlay, he finds that the prices of cows range from £18 up to £28, and Professor Long tells him that the annual cost of "amateur" cow-keeping is quite equal per head to the higher price quoted as its value; and if upon further inquiry he meets with the statement that the average annual value of the milk of a cow is £20, he will probably decide to refrain from interference with such an apparent anomaly.

No doubt many an amateur keeps his cows at an extravagant outlay which is mostly unnecessary, and the mean annual cost of cow-keeping may be placed at £13 per head, inclusive of all payments and burdens upon the land. This amount may be taken as a maximum sum which it is in the power of a shrewd practical working farmer to reduce by at least a third; and if his cows have been selected or bred with care, the milk yield, and consequently the profits, will be considerably above the average. In proof of this we may take the annual report of the milk yields of the Duke of Westminster's herds, and we find that the average yield per head last year of one herd of forty-one cows is 580 gallons, and of another of forty-two cows is 648 gallons. To show how wide is the range of yield, we find in the first herd a cow which gave only 213 gallons, while the highest yield is 1150 gallons, or a difference of 837 gallons in the yield for the year of two cows in the same herd. In the other herd there is even a greater disparity, for the

yield of one of the cows was as low as 109 gallons, while that of the best cow reached the marvellous amount of 1206 gallons, which at the reasonable value of 8d. per imperial gallon gives the very handsome sum of £40 4s. This, though undoubtedly phenomenal, is not a solitary instance of deep milking, for two other cows in the same herd gave over 1000 gallons each, and several others each gave close upon 900 gallons, and if we take the yield of the twenty best cows in the herd the average works out at a fraction over 882 gallons per head, which at 8d. is £29 8s.

Now this last average is of especial value as showing what is possible with a herd of carefully selected cows, and it is very much in accord with the three years' average of the Monewden herd of red polls in Suffolk, which was 804 gallons per head. Compare this with the computed average of 440 gallons per head of the dairy cows of the United Kingdom, and it is at once evident how inferior generally dairy cows are, and how urgent is the need for improvement. Not an easy matter is it to form a really good herd of cows, especially by a tenant farmer, and it is in the power of landlords to greatly assist their tenants by keeping a good dairy herd at the home farm, and allowing them the use of bulls, and to purchase promising young dairy stock at reasonable rates. But farmers, whether tenants or otherwise, must not wait for such help, but rather combine both for the improvement of their cows and for the more profitable disposal of milk. It has long been notorious that the retail dealer charges the consumer at least double the price paid to the farmer, who has also to pay railway carriage, and to deliver the milk to his local station. The middleman here may talk of his risk of loss, which in reality is very low, for his is mostly a ready money business, but surely that could be well covered, and a safe margin left for profit at something less than one hundred per cent? The entire milk business is now upon an unsatisfactory footing, from the breeding of cows down to the disposal of milk. It really seems ridiculous to tell a man that an inferior animal consumes quite as much, often more food than a really good one, and that a cow at £25 or £30 may prove much cheaper than another at half the price. Without combination it is really difficult to see how farmers can hope to effect a material improvement in this matter. It is not every farmer who can afford to keep a bull, and all his care and expense in the selection of cows will in the end prove practically useless unless he can breed right, and it is for this reason that we urge landlords to do their part in a reform that in the end must be for the general good.

WORK ON THE HOME FARM.

Well might Canon Kingsley sing in praise of the north-east wind, for if the clergyman of a country parish is in full sympathy and accord with his parishioners, he must share their keen appreciation of favourable weather, and his greetings at this season of the year will be all the more welcome if he is able to offer such hearty congratulations as he can just now upon the beneficial effects of this much-abused wind, in drying the surface of the land and bringing it into capital condition for the sowing of Lent corn. Not a day is lost now for turning the favourable condition of the soil to full account for sowing spring Beans, Talavera Wheat, Peas, spring Tares, and Oats as fast as possible. Men, as well as horses, must work as long as daylight lasts, and the men should be well paid and the horses well fed and well cared for in stable and field. This is not a mere question of mercy or kindly feeling, but rather of self-interest. Very generally in the eastern counties the rate of pay for agricultural labourers is only 9s. per week from Michaelmas to Lady day, and the loss of time in wet weather often brings down the pay to 6s. or 7s. Most of these men have a wife and family dependant upon them for the means of subsistence, and it is quite impossible that they can obtain enough food to enable them to do a fair day's work. Employers' means may be straitened, but in this matter they are evidently penny wise and pound foolish.

It is generally agreed that to obtain a full crop of Barley it must be sown early in a mellow, friable seed bed, but there is considerable difference of opinion as to the precise definition of earliness in this matter. Light-land men are very apt to say, "wait a bit," because they know a few hours of sunshine after rain will enable them to set the corn drill going, but the heavy land farmers dare not let slip any favourable opportunity for drilling, or they may have to wait so long for another chance that a full crop is out of the question; and why such men will persist in giving undue prominence to such a fickle crop is difficult to understand, when it is in their power to do so much better with Oats. Like so many other things in practice where custom probably obtains a

blind following in this matter, and it must not be forgotten that under ordinary cultural condition the Oat crop does not exceed Barley in appreciable degree.

REVIEW OF BOOK.

Stephens' Book of the Farm. Fourth edition. Revised by JAMES MACDONALD. Division IV. Edinburgh and London: W. Blackwood & Sons.

IN some critiques of this great work exception has been taken to the reviser's selection of authorities. Yet it is precisely this feature which imparts such importance to the revision, which embodies the teaching, in both theory and practice, of the most prominent men of light and leading. It is this which renders the manure section in Division III. so valuable, and the opening chapter in this volume on Potato planting contains Dr. A. P. Aitkens' deductions from the results of experiments of the Highland and Agricultural Society, as well as quotations from Dr. Gilbert's Oxford and Cirencester lectures. Hear him about chemical manures:—"It is shown that the exhaustion of phosphoric acid by the Potatoes was greater than that of potash; that in the continuous growth of Potatoes (at Rothamsted) it was the available supply of mineral constituents within the root-range of the plant, more than of nitrogen, which became deficient—hence the greater produce from mineral manures alone than from nitrogenous manures alone, that it is only when all the essential elements of manure are present in sufficient quantity that the full benefit of any kind of dressing can be derived; and that when thus applied together in a well-balanced dressing, artificial (nitrogenous and mineral) manures produced a crop which for twelve successive years exceeded the average yield of the United Kingdom—decidedly greater indeed than the yield from farmyard manure alone, and only about 8 cwt. per acre behind the produce from a combined dressing of dung, superphosphate, and nitrate of soda." This chapter on Potato planting, with others on the foaling season, sow farrowing, poultry, and paring and burning of rough surfaces, brings spring work to a conclusion.

Summer opens appropriately with weather notes and a summary of summer farm work. Brief chapters follow on Flax, Hemp, and Hop culture. Root crops have full and careful treatment, Turnip culture especially being given in full detail. Southern farmers will probably take exception to the advice to use Swedes for horses, which it may be assumed are used in this way by Scotch farmers as a substitute for Mangolds, that do not answer well with them. The chapters on insect pests and fungoid attacks on crops, though not exhaustive, contain many valuable hints, and are well illustrated.

Sheep management in summer has the attention and space its importance merits; shearing, lamb weaning, and ewe drafting being explained in full detail, advice of especial excellence being given upon the importance of early drafting and a young flock. Equally sound and practical is the chapter on pasturing cattle. Well says the editor:—"Give the pasture a good start. Do not be impatient to turn the cattle from the winter quarters to the summer grazing. Let cattle of all ages remain in the steading until the grass is quite ready to receive them and able to maintain them in a satisfactory condition."

The volume closes with a well illustrated treatise on dairy work. Though last, the importance of the subject has full recognition, the nature and treatment of milk, the making of butter and cheese, all having the full light of the latest leading of the best dairy authorities thrown upon it in a series of 197 of the concise, pithy paragraphs, each with its distinctive heading, which adds so admirably to the utility of the work.

REMARKS.

- 23rd.—Fine with sunshine in afternoon.
 24th.—A little sunshine in morning, overcast with spots of rain in afternoon.
 25th.—Bright morning, fine afternoon with some sunshine.
 26th.—Overcast all day, slight showers in afternoon.
 27th.—Very variable, a good deal of bright sunshine, but frequent showers of sleet and snow.
 28th.—Bright throughout.
 1st.—Cloudy early, snowing more or less nearly all day, and heavily from 1 to 3 P.M.
 On the whole a fine and dry week, but very wintry at the close. Temperature about 4° below the average.—G. J. SIMONS.

GRAPE GROWING BY ARITHMETIC.

WE always admire the zeal of vegetarians in the promulgation of their views. They believe in the beneficence of the doctrines they teach, and we should be sorry to thwart them in their endeavours to increase the consumption of vegetables and fruit. We desire to be very tolerant in dietary matters, and should express no regret if ten thousand persons joined the vegetarian ranks next week. We have very good friends who have not chewed but eschewed animal food for years, and some of them are as robust in stature as they are clear in intellect. Vegetable food is all they need, and they have no desire for any other kind. But it does not follow that the diet which answers so well for them would answer as well for all, nor would all equally enjoy it. Some of the most earnest of the crusaders, however, call upon meat eaters to sacrifice their preferences, or, in other words, claim from others what they themselves have not conceded, for they admit that animal food is repulsive to them, and they could not possibly eat it. Obviously, then, they are not martyrs to principle, but simply follow the dictates of the palate. Vegetarians, moreover, not only differ from those beyond the pale, but from each other within it. One of the thinnest of them strenuously advocates the use of raw fruits, pulse, and nuts exclusively; one of the stoutest pleads for good cooking. At one of their banquets a famous man and scientific food reformer strongly advocated the extended culture and consumption of Mushrooms. One of his allies, not so scientific perhaps, but more strongly assertive, forthwith and very forcibly condemned them, because, like meat, they contained nitrogenous compounds, or flesh formers; but all the same the favourite dish at the banquet appeared to be Mushroom pie, and of it the supply was exhausted too soon.

These remarks have been inspired by the perusal of a copy of the organ of the anti-meat fraternity in London. It is appropriately entitled the "Vegetarian," and is evidently a very respectable well-conducted journal. Its contents are varied and readable. One of the articles in the last issue contains advice to farmers, and pertains to a subject of at least equal interest to gardeners. It is headed "Fruit Culture." This is in bold type; but it is only fair to say that there is placed below it in very small type a sub-head in parenthesis, thus—"A Speculation." Probably after perusing a sample of this article most of the readers of the *Journal of Horticulture* will be of opinion that the headings would have been more appropriate if reversed in prominence. After referring to the normally depressed condition of agriculture, and condemning the advice of the "unpractical philosophers" relative to the increase of pastures for growing meat for the market, our (shall we call him "practical" philosopher?) tells the poor farmer who is looking for better times that they are not coming from that direction at all, but are "coming through the garden." But surely it must be some garden the philosopher has been dreaming about. Here are his words in all their poetic jingling.

"The good times are coming through the garden, up along the orchard, they are stealing past the bee hives, they are perfumed with the flowers, they are diamonded with dew, they are sparkling with the sunshine, their cheeks are beautiful with peachen bloom, their eyes are lustrous with the purple of the Grapes, their teeth are milky as an autumn nut, their breath is sweet as fresh ripe fruit—but they are yet a long way off. . . . Is it possible that

it can be all true? Is it possible that the stockbreeder's best investment is not shorthorns, but glass?—not fat beasts, but fruit frames? Is it possible that as many tons of hothouse Grapes can be raised on an acre of ground as are now produced in Potatoes? The imagination is staggered at a 'potentiality of riches beyond the dreams of avarice.' Talk of gold mines in the far Transvaal, talk of diamond fields in the barren vandy of the Boers—they are a delusion and a fraud when compared with the golden usury of Grapes or the diamond panes of glass.

"There are just 2240 pounds in a ton. Twenty tons of Grapes can be grown upon every acre of ground. Hothouse Grapes are now selling from 2s. 6d. to 3s. 6d. per lb. Take the lower figure, and an acre of glass land will give back the stupendous total of £5600. The ordinary agriculturist is well content if he can make £10 total produce for every acre of Wheat—*e.g.*, five quarters of Wheat at 30s., and 50s. for the straw. What a poor little miserable penury is this when placed side by side with the profit of Grapes? There is plenty of room here for the reduction of price which the development of Grape-growing will bring. Divide the gross total by 10, so that every child in the East End slums may revel upon hothouse Grapes at 1d. per lb., and there will still remain over £700 as the product per acre of land.

"Let us reason this matter out a little more closely in figures. Take a farm of ten acres devoted solely to Grapes grown under glass; assume the cost of erecting these vineries to be 2s. per square foot of land thus covered. This is a full estimate, and would include glazing, painting, hot-water piping, making of Vine beds, purchase of Vines, &c. The total cost for ten acres would be £43,560. Assume 5 per cent. for interest on capital invested and depreciation; this would give an annual charge of £2178. The other expenses might be estimated as follows:—Twenty gardeners at 30s. a week, £1560; coal, say 20 tons per diem for 100 days in the year, at 12s. per ton, £1200. This gives a gross annual expenditure of £4938, say £5000. The receipts may be estimated as follows:—200 tons of Grapes at 3d. per lb., £5600; but in addition to this may be reckoned the profits from early vegetables grown under the same roof—*e.g.*, Potatoes, Carrots, Peas, &c.; such fruits as Figs, Tomatoes, &c.; flowers for forcing—*e.g.*, Roses, Lilies, bulbs of all kinds; and the general profits from this branch of the business ought not to be less than £100 per acre. This gives a grand profit of £1600 for a year's work on a ten-acre farm. But suppose the Grapes to be sold at 6d. per lb.—and who would not rejoice at the near prospect of such an eventuality!—the fruit farmer's profit would mount by leaps and bounds from £1600 to £7200 per annum.

"And what is true of Grapes is equally true of all the finest classes of fruit. Peaches, Apricots, Nectarines, Figs, Apples, Pears, can all be grown with advantage under glass, and will well repay their shelter. Farmers, awake!"

Yes, "Farmers, awake," you have been sleeping too long. Bring out your £43,560 and cover your 10 acres; but why with this "potentiality of riches" before you, stop at 10 acres? A hundred acres would only be a small slice from some of your farms, and this could be covered for £435,600; then suppose, yes "suppose," you can grow 200 tons of Grapes, as the philosopher suggests, and sell them for 6d. a pound; also realise £1000 more by the odds and ends he mentions, you have a profit, don't you see, of £73,000? When you obtain it every child in the East End slums "will revel upon hothouse Grapes." Happy farmers; happy children! We tremble for the realisation of the "speculation." What a lucky thought to interpolate the word! The author of the programme must be something of a philosopher after all. We cannot see through it, and are bound to regard as the truest words those in which he suggests the good times of which he dreams "are yet a long way off."

Another and truly great vegetarian, physically and mentally, teaches somewhat differently. In a lecture on the "Foods of the Vegetable Kingdom," delivered at Manchester, Mr. E. J. Baillie, F.L.S., observed, "Education is needed in many departments of fruit culture, but we must also educate on other lines. We cannot live upon raw fruit alone, and we must educate people not only to use it but to use it properly cooked. We ought to have a cooking crusade as well as a whisky war. The cultivation, preparation, and distribution of foods from the vegetable kingdom offer oppor-

tunities for the exercise of all that is best for human faculty to the purer minds of those who behold in the world about them the imprint of the Father moulding and maintaining everything by the laws of life." This is the kind of teaching that gains the ear of the thoughtful and commands general respect, as sounder, more practical, and more attainable than the promulgation of visionary ideas in which farmers are told they can make fabulous fortunes by growing Grapes according to arithmetic.

ROTATION AND ARRANGEMENT OF KITCHEN GARDEN CROPS.

UNDER favourable conditions work in this department should for the ensuing two months be given an extra amount of attention, and all quarters be allotted their respective crops. Assuming that digging or trenching has been progressing apace and manure in adequate quantities has been supplied, the surface should in the course of a few weeks be in that mellow and friable condition that can only be obtained by the disintegrating action of slight touches of frost followed by dry east winds. When the ground is in such a condition no delay should occur in sowing the seed, as a sudden change in the weather may cause the state of the seed bed to be such that several weeks may elapse before it is again fit for their reception, and unless plans and arrangements are made in good time to determine the position and extent of the principal crops considerable difficulty will be experienced in more ways than one during the coming season. Much diversity of opinion exists as to the imperative necessity of the proper rotation of crops, but I am strongly in favour of carrying on a systematic order of cropping—not only on account of the scientific advantages the principle evolves, but also for practical convenience and pecuniary gain, for if a plot of ground can by the aid of intelligent scheming be made to produce two crops in the same time on the same extent of surface as one under ordinary treatment, and that too without unduly interfering with the requirements of each, such a proposition should at least have a hearing.

Taking for granted the idea that cultivated ground required a periodic rest has long since been relegated to the past, we will commence a survey of an imaginary kitchen garden where a supply of fresh vegetables has to be maintained throughout the year, and that too in such quantities that unless every foot of ground is not under a system of almost continuous cropping the demand could not be met. Such a garden at the present time would have a good breadth of autumn-planted Cabbages that were placed out immediately the Onion crop was harvested; one batch of Ellam's, sown in June or early in July, followed the Tripoli or autumn-sown Onions, and the other larger portion from August sowings of general varieties followed the spring-sown crop cleared off in September. Another equally extensive quarter would form the backbone of the winter supplies by being devoted to Brussels Sprouts; these sown on a slight hotbed in February, and planted out in April 2 feet apart in the alleys formed by earthing up the early kidney Potatoes that had been previously planted in rows 3 feet apart. These being required for use immediately frame and sheltered border supplies were exhausted no injurious interference with the Brussels Sprout plants took place, and when all the Potatoes were cleared a slight dressing of suitable artificial manure should be sprinkled on the ground around the stems of the Brussels Sprouts, and the soil from the Potato ridges levelled throughout, this resulting in a sturdy upright growth, producing firm solid sprouts from the ground to the top of the 3 feet stems. As we see them now divested of all but the crowns, and a few though none the less acceptable buds nestled under the protecting leaves at the summit, an inexperienced man would probably consider them as encumbering the ground, and proceed to decapitate them (if that had not already been done, with the mistaken notion of forcing them to produce sprouts more freely), and then consign the stems to the rubbish heap; but such would not be the procedure under the system advised. As before stated, the rows are 3 feet asunder. This space is absolutely necessary for the proper development of the plants, therefore when the plants are first put out under ordinary circumstances this surface, if not occupied by another crop, is absolute waste until the time when the advancing growth of the plant covers it, and in my estimation early Potatoes are the most desirable crop, as their requirements—both in regard to earthing up, and again when the tubers are dug—proves a decided advantage to the Sprouts. Again, the distance apart is of some importance when, as at the present time, instead of clearing them off, as is sometimes done, trenches a foot wide and 18 inches deep are driven between alternate rows, in the bottom of which a good layer of not too rotten farmyard manure is forked up, a few inches of soil

placed on this, and they are now ready for the main crop Peas. Meanwhile the Brussels Sprout stems will be producing tender succulent shoots, that, should the spring be late, will prove very acceptable to keep "the baskets going" during a few weeks that sometimes occur before the spring Cabbage is fit for use, while at the same time the crop of early, second early, and Marrow Peas are coming on apace, thanks to the protecting influence of the Sprout stems. When the supply of green stuff from other quarters is assured no time should be lost in removing the stems and getting the ground between the rows of Peas forked over, and having drawn three shallow drills some 6 inches apart down the centre of the open space Round or Summer Spinach should be sown at once. The first sowings of Peas in these trenches should consist of Veitch's Early Selected, William I., and Duke of Albany. An equal quantity of each sown at the same time, say about the last week in February or early in March, will form a reliable succession to each other, and these, followed by further fortnightly sowings of the "Duke" until the end of June, when *Ne Plus Ultra*, followed by William I., will give a good supply under favourable circumstances far into the autumn.

But to resume our survey of other quarters. A good crop of Turnips, of the Red Stone and Chirk Castle type, will have resulted from a favourable opportunity of raising the plants quickly by sowing on a plot that had been made especially rich for mid-summer Cauliflowers, and also conveniently vacant in time for the sowing of winter Turnips. A good quantity of these will be stored in cool places for soup-making purposes until the frame varieties are fit for use; the remainder will furnish useful greens, and will be finally cleared away or dug in with manure, and the quarter planted with Leeks from the seed beds. Another piece of ground will probably be occupied with the stumps of the previous spring Cabbage, that have done good service throughout the summer and autumn, and even now should not be despised before a continuous supply is apparent. On several occasions have I seen the folly of being too hasty in destroying old stumps of Brussels Sprouts, Cabbages, and the various winter greens on the first appearance of fine spring weather, which proceeding has resulted in an almost "green famine," consequent on a change in the weather, and what at first promised to be a fine early spring eventually proved one of the latest and coldest on record.

This again brings the forcible necessity of some arrangement whereby the supplies can be held in reserve in case of emergency, and at the same time not interfere with the operation connected with other crops. This can only be accomplished by careful forethought and the following out of a fixed plan in the rotation of these crops if the object is to obtain the fullest return possible.

Plantations of early Broccoli should now be turning in. The seed was sown last May and June, and the plants put out after early Potatoes were lifted. Later sorts of Broccoli were pricked out from the seed-beds and followed later Potatoes, and some of the latest planted behind a north wall should prolong the season until the early forced Cauliflowers are fit to cut. These quarters can be cleared of stumps and planted with Potatoes at once, and portions according to discretion dug and manured for Dwarf Beans and other suitable succession crops. Not that I advocate the absolute necessity of following a hard-and-fast rule of the scientific principle of crop rotation, which is that a crop of the same natural order should not follow one also belonging to the same order, yet when it can be complied with in a convenient manner, this idea being based on a reasonable theory, is worthy of consideration. Other quarters that have been cropped with Carrots, Parsnips, Salsafy, and Leeks will have been manured, dug, or trenched at discretion, and will be now awaiting the reception of the crops, as will also other plots previously occupied with Savoy, Coleworts, late Lettuces, late Peas, late Cauliflowers, Dwarf and Runner Beans, and various small crops that occupied the ground until destroyed by autumn frosts.

Warm sheltered borders and cosy nooks should have the best of attention to enable them to be made the most of. Early Peas, Beans, Cauliflowers, Lettuces, Potatoes, and Radishes can be obtained fit for use several weeks before those from more open quarters, and, by good management, in satisfactory quantities, from these always too restricted spaces. At present they should be in readiness for planting and sowing when a favourable opportunity occurs. One of the most prized of early crops is that of Peas, and this is invariably the same in the majority of establishments; and as hard forcing cannot be carried on to any great extent with the same facility as with Dwarf Beans, this also renders them more valuable when produced early and in fair quantities. A practice that I have found to meet these requirements must be devoted to a separate article, as this is merely a survey to locate the crop for the ensuing season.

Where Potatoes are grown in bulk in the garden proper, they

should be so arranged to follow winter greens, such as Turnips and Coleworts, so as to allow no loss of time, as would often occur if Brussels Sprouts and Broccoli were the predecessors. But if it can be managed, late vigorous varieties, such as *Magnum Bonum*, *White Elephant*, and *Champion* are for several reasons best grown on farm land. Although the quarter occupied by Cabbages last season will come in well for early or late varieties of strong growth, it is always desirable to have as few late Potatoes in the garden as possible.

Celery will require a good proportion of space allotted to it. Late Broccoli makes a good crop to arrange for this to follow, though not the best; but the disadvantage of following late Peas or Dwarf Beans lies in the ground remaining vacant for a longer period than we should wish, although in following these crops the soil is less likely to be infested so badly with slugs as when succeeding Cabbages of last year's crop, or Brussels Sprouts that have had a season's opportunity of harbouring these undesirable pests. The space that is now becoming vacant by finishing up this season's Celery may be portioned out for Carrots and succession Marrow Peas, Turnips, Onions, or laid out for new Strawberry beds, old plantations of which may be destroyed after the fruit is gathered, and Broccoli planted on the undug surface with the aid of a crowbar. This is a practice I would recommend where the crops of Broccoli suffer from frost, the firm woody stems resulting from the hard root-run being better able to withstand the frost; also the Strawberries are ready for clearance in convenient time for the Broccoli plants.

Seakale and Parsnips are well adapted to change plots, but care should be taken not to allot the quarters occupied by Seakale indiscriminately, and unless it can be changed, to allow a strong growing crop to follow, as Parsnips or late vigorous Potatoes; it is best to accept the lesser of the two evils, and keep it to one permanent quarter where, with generous manuring, it will continue to thrive for a number of years. Like Horseradish, this root is most difficult to eradicate when once established in good quarters.

Such is an outline of a few methods by which the produce may be augmented from limited sources, and although much can be done by careful planning, care should be taken to determine whether intended arrangements have the true ring of economy, for unless such be done the probable results are not always of a satisfactory nature.—M. COOMBE.

GARDEN PESTS.

If a fresh planting be made, be it of flowers, vegetables, or trees, that is where pests will be found, and of equally general application is the fact, that once allow a bird or other creature to make its ravages unmolested, and it will not be long before all its friends and relatives will be feasting and making merry. I have seen acres of young plantations surrounded with 3-foot wire fencing destroyed in a few weeks, for the simple reason that the earlier colonists were allowed to work unmolested, and their numbers were steadily increased by others who had doubtless heard of the wonderful land. When once a footing has been gained the mere stopping of holes is not always sufficient to prevent their incursions, for educated hares will jump fences, and their less agile friends, the rabbits, can find a way over by climbing them. It is one of the commonest experiences, where pheasants are allowed the run of gardens, or where peacocks ramble among flower beds, for both these birds to take to certain plants one season, and another year their taste, judging by the plants attacked, be entirely changed. But I think the explanation is to be found in both cases in the birds beginning at the commencement of the season on some particular plant, and continuing to eat that in preference to others, the following year a different plant being most ready for consumption when operations are resumed.

The only efficacious antidote is annihilation, but the gardens and grounds are numerous where no such drastic measures dare be entered on. The following means of lessening damage, it is hoped, may be useful. Rabbits can only be kept at bay by means of efficient fencing; but much fencing, though it looks efficient, is really not so. In the first place the mesh is often too large; 17 gauge 1½-inch mesh is the largest size that should be used, but sometimes a young rabbit will find its way through this size. Twice in eight years I have known a rabbit pass through this mesh. If the plantation or ground to be protected is of any extent the wire must be 3 feet wide. The method of supporting this wire may either be by means of wooden stakes and rails or of iron and wire, but either way it must be so fixed in the ground as to puzzle rabbits to burrow under it. Merely sinking the wire a few inches in the ground will not be sufficient; but by bending it outwards 3 inches and sinking the whole sufficiently deep to leave 2 feet 6 inches above ground the rabbit will be a wonderfully

cute one that will find his way through. For single trees the wire need not be sunk, and 2-foot wire is quite deep enough. Where hares are plentiful it is necessary to employ a wider wire for Hollies, hares being very partial to these, standing over the edge of the wire to reach the leaves and shoots. Standard or bare-stemmed trees may be protected by a collar of netting, but generally a mixture of clay with cowdung and water, painted as high up as the animals can reach, will afford an efficient protection and keep its properties good for at least twelve months.

Squirrels are particularly destructive, and there is no cure save shooting. Where squirrels abound no Conifer is safe, and in spring much damage is done to deciduous trees; but it is when they visit the garden that they become unbearable. I have watched individuals operating on Peaches, Plums, and other fruits, and the certainty with which they selected the best specimens in succession, and the astonishing rapidity with which these were in turn discussed and others taken up to disappear in a like manner, would have been interesting had one's feelings been less personal. The only safety for fruit is to kill the first intruder, as if left for a few days every squirrel within visiting distance will be on his holidays, and have Mrs. S. and those of the family who are of a visiting age along with him.

The rat not undeservedly bears the name of being the most longheaded and the least sentimental of all vermin, and consequently he is the most capable of looking after his personal safety while on his ravaging expeditions. If no attention is paid to him, or if the duty of extermination is performed in a perfunctory manner, he will stay on in the same place, bring up a family worthy of patriarchal times, and have a good time of it generally. But if the chase is hot he and all his belongings will quickly shift their quarters, though in due time an incursion will be made to see how things are going on. When times are hard the rat will eat anything. Of course he prefers a well ripened bunch of Grapes or a luscious Pear, and in the way of vegetables if he can set up a home in a pit of Potatoes he is fairly comfortable. Newly planted bulbs are choice morsels, and when very hard pressed he is not averse to the stems of Sprouts and Broccoli, with a bit of Pelargonium for a change. Trapping will destroy a few, but the great drawback to traps is the assumption the untrapped portion of the community form that if a trap is bad for one rat it must be bad for all, and consequently they either get out of the way of traps or withdraw to another feeding ground for a time. There is one thing which a rat is too weak to pass, and if he partake of it the one time his chances are over, and that is phosphor paste. Mix the paste on bits of bread, and wrap it in paper rolled up in the shape which grocers employ for small purchases, leaving just a little bit open to allow the curious to see there is something worth investigating; and very soon a pretty quarrel will ensue as to who is to have the most, the morning revealing the partakers of the feast close by in comfortable attitudes, but all dead.

Mice, like rats, are very destructive, but apart from a good hunting cat, trapping is the best method of destruction. When they are numerous or hard on Peas I have found this to keep them at bay. Fill a bottle with petroleum, close the mouth with a cork in which a quill is inserted, and through which the oil can be sparingly dribbled over the surface of the lines under which the Peas are.

Of feathered pests the wood pigeon is very destructive, and difficult to get rid of when once a garden becomes frequented. I know no better method of keeping them away than by going over all the nests in the near neighbourhood of the garden, taking and destroying them and the eggs. When this is done effectually no pigeon will trouble the garden. But once allow a pair to feed, and when and where the nuisance will stop it is impossible to say. They break through nets, and are averse to no kind of young vegetables or fruit, Cauliflowers, Broccoli, Cabbages, Peas, Currants, Gooseberries, and Strawberries being the crops most commonly destroyed. Though pheasants do not perhaps come rightly under the name of vermin, yet as they are often the means of great loss, a few words here may not be out of place. One thing ought not to be done with these, however great the temptation may be, that is to kill them. No proprietor fond of game would allow such a thing; and if on pointing out the damage that is being done no remedy is provided, then all that the gardener has any right to do is to protect his crops, and if possible starve them out. Pheasants are particularly fond of Pinks, Carnations, Potatoes, Artichokes, and young Peas. In certain seasons they will evince a liking for young Lettuces and Brassicas, and a few other plants, but the above are chiefly those damaged. The two first named we have to protect with herring nets during the winter season. Peas have always to be protected. I have seen a few hundred yards destroyed during the dinner hour through being left uncovered for

that short time. They begin directly the Peas are sown. A sure method is to sow in narrow trenches, and either draw herring nets over the ground or cover each line with wire netting, taking care that the ends are closed. As a rule I prefer the herring netting, as it is necessary to protect until the plants are a good size, and these can be drawn over the stakes with little trouble. To keep the pheasants from Lettuces I have tried dusting the foliage with soot. This is sometimes effective.

Blackbirds and thrushes must be kept from fruit by means of close netting, and it is a very great consideration to have fruit quarters protected before any fruit is ripe. Unless one has had experience it would hardly be credible the difference this makes, for if once either of these begin a course of fruit diet they will eat nothing else as long as it is to be seen or found. Of late years sparrows, chaffinches, and other small birds have been enormously destructive to autumn crops alike in fields and gardens. Here we have to grin and bear it. A neighbouring proprietor set his gamekeepers on to the sparrows, but these proved too much for guns and shot, and they had to give up the pursuit defeated.—B.

DAHLIA ANALYSIS—1883-1889.

At no previous show have the different types of Dahlia been so completely represented as at the Exhibition of the National Dahlia Society held at the Crystal Palace in September last. The centenary class formed a new feature of special interest. Several of the exhibits in this class, in which all kinds of Dahlias were for the first time gathered together into one group, were remarkably good. To say nothing of the beauty of the individual flowers and the great taste displayed in their arrangement, these collections were very instructive, for they showed at a glance what a variety of form and colour this grand early autumn flower is capable of, and at the same time what rapid advances in nearly all sections it is now making. Only a few years ago such effective and varied displays would have been altogether out of the question, owing to the want of a sufficient number of suitable varieties.

The introduction of this centenary class has unfortunately not proved beneficial to our analysis, for many of the flowers which would otherwise have appeared in the ordinary classes were used to adorn these novel and interesting collections. Fortunately the Shows and Fancies

suffered much less from this cause than the Pompon, Cactus, or single Dahlias. Owing, however, to the dry and forcing weather which prevailed at the end of August and during the early part of September, the competition in these two divisions was less keen than at either of the two preceding shows, for under these unfavourable conditions, and particularly in the early districts, many promising young blooms destined for the show were over before the Exhibition took place. The total number of Show and Fancy Dahlias staged in competition at the last seven shows has been as follows:—

	1883.	1884.	1885.	1886.	1887.	1888.	1889.
Shows... ..	692	754	837	840	1106	1158	922
Fancies	269	425	355	387	350	315	274
	961	1179	1192	1227	1456	1473	1196

It will thus be seen that the Show Dahlias were last year more numerous than at any of the previous exhibitions, with the exception of those of 1887 and 1888. On the other hand there were scarcely any more Fancies than in 1883—the first and smallest exhibition of the series.

The averages upon which the positions of the different varieties in the two tables depend have been calculated as follows. For those Dahlias sent out prior to 1883, the average is for the whole seven years, for the 1883 sorts six years, for those of 1884 five years, for those of 1885 four years, for the 1886 kinds three years, and for those of 1887 two years. The still newer kinds find places according to the number of times they were staged at the last Exhibition only.

Coming now to the table of Show varieties, the most striking feature, as has been the case in recent years, is the remarkable position occupied by Mrs. Gladstone in respect to all other Show Dahlias, a position altogether unique amongst florists' flowers; indeed, at the last four exhibitions this superb flower has been staged very nearly twice as frequently as any other Dahlia, and was to be seen in almost every stand in which it was admissible. The following established varieties appeared in unusually good form last year—William Rawlings, Ethel Britton, Prince Bismarck, Clara, Harrison Weir, Imperial, George Rawlings, and notably Shirley Hibberd, which was shown in many more stands than at any previous exhibition. On the other hand those two old favourites, the Hon. Mrs. P. Wyndham and Henry Walton, which until the appearance of Mrs. Gladstone stood together at the head of the analysis, were staged only about half as many times as in former years. The same might also be said of Goldfinder, Mrs. Harris, T. J.

FANCY DAHLIAS.

Position in Present Analysis.	Average Number of Times Shown in the Seven Years.	Number of Times Shown in 1889.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	18.0	22	Mrs. Saunders	1872	Turner	Yellow and white.
2	16.5	12	Gaiety	1879	Keynes	Yellow, red and white.
3	15.6	16	Rev. J. B. M. Camm	1873	Keynes	Yellow and red.
4	12.1	7	Chorister	1881	Keynes	Fawn and crimson.
5	12.0	16	Henry Eckford	1886	Rawlings	Yellow and red.
6	10.6	16	Duchess of Albany	1884	Turner	Orange and crimson.
7	10.5	12	Flora Wyatt	1871	Keynes	Orange and red.
8	10.0	11	Mrs. N. Halls	1881	Rawlings	Scarlet and white.
9	9.9	14	Hugh Austin	1881	Keynes	Orange and red.
10	9.6	10	George Barnes	1878	Keynes	Lilac and crimson.
10	9.6	9	Peacock	1877	Turner	Maroon and white.
11	9.3	3	Fanny Sturt	1868	Pope	Red and white.
12	9.2	6	Professor Faweett	1881	Keynes	Lilac and brown.
13	8.5	4	John Forbes	1882	Keynes	Maroon.
14	8.3	5	Henry Glasscock	1875	Keynes	Buff and crimson.
15	7.8	6	Rebecca	1883	Keynes	Lilac and crimson.
16	7.7	3	General Gordon	1885	Keynes	Yellow and scarlet.
17	7.1	6	James O'Brien	1881	Keynes	Yellow and crimson.
18	7.0	7	Dorothy	1888	Keynes	Fawn and maroon.
19	6.7	3	Egyptian Prince	1873	Keynes	Orange and red.
20	6.6	1	Miss Browning	1880	Keynes	Yellow and white.
21	6.3	0	Miss Lily Large	1876	Keynes	Yellow and crimson.
22	6.0	9	Edmund Boston	1887	Keynes	Orange and crimson.
22	6.0	1	Hercules	1877	Keynes	Yellow and crimson.
23	5.7	5	Eric Fisher	1886	Keynes	Buff and scarlet.
24	5.5	8	Frank Pearce	1886	Rawlings	Rose, striped crimson.
24	5.5	1	Lotty Eckford	1884	Eckford	White and purple.
24	5.5	7	Prince Henry	1887	Fellowes	Lilac, striped purple.
25	5.3	1	Oracle	1877	Fellowes	Yellow and crimson.
26	5.1	1	John Lamont	1875	Keynes	Maroon and black.
27	5.0	3	Pelican	1886	Keynes	White and purple.

Saltmarsh, Joseph Ashby, James Vick, Flag of Truce, Vice-President, and several other well-known kinds.

There are five 1886 varieties in the list. Of these Harry Keith now occupies a splendid position, standing as it does only second to the premier flower—Mrs. Gladstone. Next come Mrs. W. Slack and R. T. Rawlings, both at No. 8, the former having gained two and the latter no fewer than thirteen places since last year. Mr. Glascock (No. 44) has made a slight move upwards, while Thomas Hobbs has fallen from No. 26 to No. 33.

The year 1887 was prolific as regards new varieties. At the head of these, at No. 9, we find Colonist, and a little lower down J. T. West

(No. 14), almost immediately followed by Willie Garratt. Then in the following order come Queen of the Belgians (No. 29), Crimson King (No. 32), Mrs. G. Rawlings (No. 40), Bendigo and Eclipse (No. 42). Colonist and Willie Garratt have each made good progress since last year, while Crimson King, Mrs. G. Rawlings and Eclipse have all more or less improved on their former positions.

The following appear for the first time in the analysis. Purple Prince and Nellie Cramond, both of which came out in 1888, already stand at No. 20 and No. 29 respectively, while Maud Fellowes, an 1889 variety, just manages to secure a place.

In the table of Fancies, quite unlike that devoted to Show varieties,

SHOW DAHLIAS.

Position in Present Analysis.	Average Number of Times Shown in the Seven Years.	Number of Times Shown in 1889.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	42.8	45	Mrs. Gladstone.....	1884	Hurst	Pale blush.
2	26.0	35	Harry Keith	1886	Keynes	Rosy purple.
3	22.4	22	James Cocker	1871	Keynes	Purple.
4	21.7	28	William Rawlings	1881	Rawlings	Crimson purple.
5	21.0	10	Hon. Mrs. P. Wyndham	1881	Keynes	Pale yellow and rose.
6	19.6	11	Henry Walton	1873	Keynes	Pale yellow and scarlet.
7	17.5	22	Ethel Britton	1880	Keynes	White and purple.
7	17.5	7	Goldfinder	1881	Fellowes	Yellow and red.
8	17.3	17	Mrs. W. Slack	1886	Keynes	Blush white and purple
8	17.3	28	R. T. Rawlings	1886	Rawlings	Clear yellow.
9	17.0	19	Colonist	1887	Keynes	Chocolate and fawn.
10	16.4	16	Prince of Denmark	1881	Fellowes	Dark maroon.
11	16.2	8	Mrs. Harris	1873	Harris	White and lilac.
12	15.6	18	Prince Bismarck	1879	Fellowes	Puce.
12	15.6	25	Shirley Hibberd	1881	Rawlings	Dark crimson.
13	15.3	14	Mrs. Langtry	1885	Keynes	Cream and crimson
14	15.0	11	J. T. West	1887	Rawlings	Yellow and purple.
14	15.0	8	T. J. Saltmarsh	1885	Rawlings	Yellow and chestnut.
15	13.5	15	Willie Garratt	1887	Garratt	Bright cardinal.
16	13.4	4	Joseph Ashby	1879	Turner	Shaded orange.
17	13.3	5	James Vick	1881	Keynes	Purplish maroon.
18	12.0	6	Flag of Truce	1868	Wheeler	White and lilac.
18	12.0	2	Vice-President	1868	Keynes	Orange.
19	11.8	18	Clara	1879	Rawlings	Rosy peach.
19	11.8	17	Harrison Weir	1883	Rawlings	Yellow.
20	11.0	11	Purple Prince	1888	Turner	Rosy purple.
21	10.9	9	Mrs. Dodds	1881	Keynes	Blush and lilac.
22	10.8	11	John N. Keynes	1871	Keynes	Yellow.
23	10.6	6	Burgundy	1877	Turner	Dark puce.
24	10.0	14	Imperial	1883	Keynes	Purple, shaded lilac.
25	9.7	13	George Rawlings	1882	Rawlings	Dark maroon.
25	9.7	12	Miss Cannell	1881	Eckford	Cream and crimson.
26	9.5	8	Mr. Harris	1881	Rawlings	Crimson scarlet.
27	9.4	13	Mr. Shirley Hibberd	1877	Rawlings	Cream and pink.
28	9.3	15	Hope	1883	Keynes	Light rosy lilac.
29	9.0	5	Mrs. F. Foreman	1884	Keynes	Lilac.
29	9.0	8	Mrs. G. R. Jefferd	1884	Keynes	Deep yellow.
29	9.0	9	Nellie Cramond	1888	Keynes	Purple, shaded cerise.
29	9.0	7	Queen of the Belgians	1887	Rawlings	Cream and pink.
30	8.7	9	Mrs. John Laing	1883	Keynes	French white.
31	8.6	7	Earl of Ravensworth	1883	Harkness & Son ..	Lilac.
31	8.6	14	John Bennett	1875	Rawlings	Yellow and scarlet.
32	8.5	9	Crimson King	1887	Keynes	Deep crimson scarlet.
32	8.5	10	James Stephen	1882	Keynes	Orange scarlet.
33	8.3	4	Thomas Hobbs	1886	Keynes	Purplish rose.
34	8.2	8	John Standish	1872	Turner	Crimson.
34	8.2	2	John W. Lord	1877	Keynes	Orange buff.
35	7.9	6	Constancy	1878	Harris	Yellow and lake.
36	7.8	7	John Henshaw	1883	Rawlings	Ruby crimson.
37	7.6	5	John Wyatt	1877	Keynes	Crimson scarlet.
38	7.3	8	Champion Rollo	1881	Keynes	Orange.
39	7.1	3	Royal Queen	1875	Eckford	Cream and crimson.
40	7.0	7	Joseph Green	1881	Keynes	Crimson.
40	7.0	7	Mrs. G. Rawlings	1887	Rawlings	Blush and purple.
40	7.0	5	Sunbeam	1881	Fellowes	Buff.
41	6.9	8	Walter H. Williams	1881	Keynes	Bright scarlet.
42	6.5	4	Bendigo	1887	Turner	Purplish crimson.
42	6.5	9	Eclipse	1887	Keynes	Orange scarlet.
42	6.5	2	Mrs. Douglas	1845	Rawlings	Scarlet.
43	6.4	9	Herbert Turner	1873	Turner	French white.
44	6.3	7	Mr. Glascock	1886	Rawlings	Purple.
44	6.3	6	Rev. J. Goodday	1879	Rawlings	Maroon, shaded purple.
45	6.1	4	Ovid	1874	Turner	Purple.
46	6.0	6	Maud Fellowes	1889	Fellowes	Pale pink, shaded purple.

the premier position has throughout been fiercely contested. For the first four years Gaiety took the lead, but in 1887 had to give way to Mrs. Saunders. In the next analysis they were bracketed as equal, and now Mrs. Saunders once more proceeds to the front. The Rev. J. B. M. Camm has also proved very constant, never dropping far behind these two well matched rivals. Mrs. Saunders, Duchess of Albany and Hugh Austin were particularly well shown, but not so Gaiety, Chorister, Fanny Sturt, John Forbes and General Gordon, which were staged much less frequently than usual.

There are four 1886 Fancies in the analysis, Henry Eckford, which has already risen to No. 5; Eric Fisher, which has not improved on its previous position, being still at No. 23; Frank Pearce (No. 24) which appears on the list for the first time, and Pelican, which has dropped to the very bottom of it.

The year 1887 is represented by Edmund Boston at No. 22 and Prince Henry at No. 24, while Dorothy, the sole representative of 1888, has already mounted to No. 18.

Pompon, Cactus and Single varieties at the 1889 exhibition of the National Dahlia Society. Pompon.—Over fifty sorts were staged in all. Those shown four or more times arrange themselves as follows: E. F. Junker, Darkness, Favourite, Rosalie, Golden Gem, Gem, Little Duchess, Cupid, Isabel, Leila, White Aster, Admiration, Dora, Guiding Star, Lady Blanche and Whisper.

Cactus and Decorative.—More than thirty kinds were exhibited, but only the following were found in two or more stands. Mrs. Hawkins, Empress of India, Amphion, Charming Bride, Constance, Juarezii, Panthea, Lady Marsham, Cochineal, William Rayner, Annie Harvey, Beauty of Brentwood, Henry Patrick and Mrs. Tait. Single.—Nearly forty varieties were shown in the different stands, but only ten were represented by more than a single flower—namely, Amos Perry, Formosa, Miss Henshaw, Sunningdale White, Enchantment, Hugo, Marion Hood, Sunningdale Yellow, Victory, and White Queen.

It will thus be seen that the Cactus and Single Dahlias are as yet scarcely ripe for tabulation. With more classes devoted to them in the schedule, and stronger competition, somewhat better results may be hoped for another year.—E. M., *Berkhamstead*.

VANDAS.

PLANTS in a sickly condition can soon be detected by the yellow appearance of their foliage, which may have resulted from too much water and a soddened condition of the soil about their roots. The sooner plants in an unsatisfactory state receive attention the better. The most certain method of restoring them is to wash from their roots all decaying matter in tepid water, and then cut away dead and decaying roots and suspend them in a warm moist atmosphere from the roof in a sloping position, so that water from the syringe will not lodge in the axils of their leaves. When subjected to this treatment it is necessary to syringe the plants once or twice daily, according to the weather. When they commence the formation of new roots the plants may be placed in pots or baskets, whichever are most convenient and most likely to meet the requirements of the cultivators. Another plan, and an excellent one, is to return them to pots after the roots have been washed and trimmed. The pot should be drained in the usual way, half full, and the remaining space to within an inch of the rim filled with large pieces of crock and charcoal. This will steady the plant, and keep it in position until new roots commence forming. It will be necessary to syringe the pot occasionally, or pour tepid water into it to keep moisture about the plant. Unless the plants are in an unsatisfactory condition they will soon emit fresh roots and re-establish themselves. *Aerides* and *Saccolabiums* that are in poor condition may have the same treatment.

POTTING VANDAS, AERIDES AND SACCOLABIUMS.

These may now be top-dressed or repotted as occasion requires. If the plants need larger pots some care is requisite. The old material should be picked out from amongst the roots, and if the plant cannot be lifted out of the old pot it should be carefully broken, as some of the roots will be clinging to its sides. These should not be disturbed, the portions of pot clinging to the roots being placed into the larger pot. The space to within an inch of the rim can be filled with crocks, large pieces at the base, gradually reducing their size until a layer of small pieces can be placed on the top. When the plants are small crocks only are used, but when 8, 10-inch, or larger pots are employed we prefer a fair proportion of charcoal in good sized lumps. If a plant is turned out and the roots are found to cling to the crocks only charcoal is not again

used, the space being filled with crocks. It may here be stated that no peat is used for these plants. We prefer clean living sphagnum. This when cleared of all rubbish should be cut with shears and pressed moderately firm in the pot, slightly raising it above the rim. On the surface should be placed a thin layer of moss that has been selected, consisting of growing portions. This may be encouraged to grow by syringing it gently. Care is needed in doing this, for the moss may be made too wet at this early stage. Inexperienced growers would act wisely in deferring the final surfacing until growth is active and liberal supplies of water are beneficial.

TOP-DRESSING.

Where plants do not need larger pots and the drainage is perfectly clean the whole of the moss in which they have been growing during the past twelve months should be removed. This is important where the moss used is not of the best quality and of a nature to decay quickly, which some of it will do in less than one season. If the moss used has been really good only a thin surfacing will be needed. But when the least sign of decay can be observed it should be removed. Many plants are brought into an unhealthy condition through negligence of these matters. When it is removed supply fresh exactly the same as if the plants were repotted.—ORCHID GROWER.

THE ROTATION OF CROPS.

In the cultivation of the ground, whether it be in the garden or on the farm, it is necessary that proper attention be paid to a regular rotation of crops, this being one of the first and principal features of good management. By a rotation of perennial crops—such as Raspberries, Currants, and Gooseberries—the ground to a certain degree is renewed and rested, or at the least very much improved. The above mentioned need not occupy a certain piece of ground above twelve years, or under three. This, with trenching for the principal autumn crops of Brassicas, will keep the ground in good order, and with no loss of space. In all gardens new plantations should be made annually, which will throw a certain portion of the ground into rotation. All crops for a few years will be found to thrive well on newly turned up maiden soil, but would degenerate in a few years unless supplied with fresh soil. This holds good with "Ex-Farmer," on page 126, as grasses must eventually give way to other plants if not properly provided for. As far as practicable rotation should be provided for in all gardens, as by keeping all the Brassicas, Legumes, bulbs, and other light crops in separate portions, each to follow in regular succession; not only would it give the garden a better appearance, but to a certain measure would produce the necessary change for their well doing. All plants draw their own peculiar substance from the soil, so that a piece of ground which has nourished one crop may be found sufficient for the well-doing of another of a different kind. A plant may be found in abundance in certain fields or woods for a number of years, but in course of time, unless the soil be replenished, will wholly disappear.

Nothing can relieve the soil more than a regular rotation of crops if carried out judiciously, so that the proper plants may succeed each other. For example, take a quarter of Asparagus, the roots of which are large and have penetrated to a great depth, and which have been in the same place for a number of years, and in consequence have exhausted the soil and ceased to thrive. If instead of replanting with young roots of the same kind the ground be cropped with plants, the roots of which do not run too deep, they will find sufficient nourishment of a different kind from that necessary for the former crop, or absorb that which the roots were too deep to benefit by. Perhaps the general richness of the gardens, by much manure been used for the production of vegetables, more attention has been paid to the courses of cropping on the farm than in the garden, but the same principles are applicable to both. There are, however, many circumstances to prevent its being accomplished in the garden so effectively as in the fields—viz., the smallness of the portions allotted to this object, the number to be produced, and their great similarity to each other.—A.

FRITILLARIA RACEMOSA.

FOR very many years there has been growing in a border under the south-west wall of the Oxford Botanic Garden a clump of modest dimensions of an uncommon *Fritillaria*, named *F. racemosa*, that forms the subject of these notes. Writing from memory renders it difficult to describe accurately the colour of the flowers, but some idea may be formed by stating that the smooth-surfaced petals are of a purple shade of chocolate, splashed or streaked and

spotted with bright green, and surrounded by an irregular margin of yellowish green, which extends to their edges. When these were at their best last season Mr. Baker, the Curator of the garden, obligingly gratified the writer's desire to have a characteristic specimen, from which a drawing has been made and forwarded to the Editor with a view to its identity being determined, and some idea of its distribution in this country ascertained. Concerning its origin but little can be gleaned. There does not appear to be any record of the introduction of this plant into the garden, and very little information can be obtained respecting it. It is, however, certain that for many decades it was confined to the same sheltered spot, in which it can be remembered as growing for a long period before one of the most charming of old garden flowers which bordered on it—the dainty pale-blue Wood Anemone—acquired the name of *A. nemorosa* Robinsoniana; here, seemingly, as though designed to afford the protection of shade or shelter during the stages of maturation, at the rear of it a Mandrake plant, *Mandragora vernalis*, extended to it its ample leaves. Such is the situation in which the *Fritillaria* has flourished. It may be mentioned as of some interest that it is one of the many plants that for generations have been preserved within the imposing old walls of what erst was known as the Oxford Physic Garden, and which in well remembered cases were from thence redistributed after having been for long lost sight of in this country as living specimens.

Evidently *Fritillaries* thrive remarkably well in this garden; the situation for them is as favourable as could be desired, and consequently they produce annually an abundance of flowers. Outside the garden, too, in the meadows through which the rivers Isis and Cherwell flow (the latter of which forms the boundary of the garden on the eastward side), notably in that of Christ Church, within view of the confluence of the two streams, the native chequered *Fritillary* abounds in all its most familiar forms. These curiously shaped flowers with, in many instances, their mosaic-like markings cannot be definitely localised, for they are to be met with over a very wide area. They extend, as is locally well known, up the rivers' sides, and in respect to the principal one to a distance as far as Thames Head, the indisputable source of the river, and of much past controversy therewith. Within easy walking distance of this point there is a field that has been famed for them time out of mind. Owing to their comparatively early period of flowering they are not as well known to the majority of people as many of the indigenous riverside summer flowers, for before the genial weather that contributes so much to the pleasure of those accustomed to resort to the river can invest it with the chiefest charm of its attractiveness the *Fritillary* flowers have vanished. An account of their extensive growth in the Oxford meadows has already appeared in the pages of this Journal, and notwithstanding the enormous quantities that are annually gathered they reappear year after year apparently undiminished. So long as the flowers only are plucked there need be little apprehension of their eventual partial disappearance from the meads in which they now luxuriate, but there is, unhappily, occasion to raise an emphatic word of warning in the presence of the fact that entire plants when in bloom are extensively collected for sale, and these, as may be imagined, when planted regardless of their requirements almost invariably perish. Until quite recently, however, the *Fritillaries* have been chiefly sought for by those possessing a fondness for flowers, whose desires in respect to them would be satisfied in gathering a well-chosen handful, and who would regard them with perhaps as much favour as many expensive exotic blooms from having been afforded some delight in obtaining them. It will be understood as being an entirely different matter fraught with palpable significance when whole fields are denuded of them by itinerant wild-flower gatherers, who in increasing numbers collect them with unrestrained activity for dispatching to various destinations. The most reprehensible practice, however, is that of removing the roots in a wholesale manner, for which the severest censure is justifiable when it is remembered that were it not for the prospect of its continuation the Snake's-head *Fritillary* might be considered as being permanently established in the river meads of the University, where they are, particularly when seen for the first time, of sufficiently striking appearance to excite admiration, as well as to arouse into action the acquisitive propensity that is so essentially human.

Parkinson states, in Chapter iv. of his "*Paradisus Terrestris*" (1629), that "of *Fritillaria*, or the chekered Daffodill, there are halfe a score seuerall sorts, both white and red, both yellow and blacke, which are a wonderfull grace and ornament to a Garden in regard of the checker like spots are in the flowers." Such was his estimation of them when recording "the nature and names of diuers Out-landish flowers, that for their pride, beauty, and earliness, are to be planted in Gardens of pleasure for delight." No particular medicinal virtues appear to have been accredited to the

Fritillaria, for he remarks that "the chiefe or only use thereof is, to be an ornament for the Gardens of the curious lovers of these delights and to be worn of them abroad." Of the more than forty kinds at present known he describes twelve, and of these he illustrated eight, observing of the native *F. Meleagris* that it "beareth two flowers, and seldom three." This species derived its name, as implied, from the appearance of the flower resembling the markings of the feathers of the guinea hen, and according to Parkinson "was brought to our knowledge from Orleance" under the name of *Narcissus Caparonius*, given to it in compliment to Noel Caperon, who first discovered it, and who was, "after the finding thereof, taken away in the Massacre in France, recalling a period of one of the most heartless fanatical persecutions and horrible sacrifice of human lives ever sanctioned or perpetrated in the name of religion."

A *Fritillaria racemosa* is figured in the "*Botanical Magazine*,"

FIG. 29.—FRITILLARIA RACEMOSA.

vol. xxx., t. 1216, from a specimen bearing only two small flowers, and this is said to be the one frequently mentioned by Pallas in his travels under the specific name of *Meleagris*, for which he mistook it. Under the same name a plant is figured in the "*Botanical Magazine*," vol. xxiv., t. 952, having four blossoms, stated as being "evidently the plant from which Linnaeus characterised his *pyrenaica*." The figure in the "*Magazine*" undoubtedly represents different forms to that of the Oxford Botanic Garden. In passing it may be of interest to note, in confirmation of the admitted absence of any particular medicinal virtues of *Fritillarias*, in "*Stirpium Icones Chabrai*" (1666) the author, an M.D., wrote, "*Fritillariae autem vsus Medicus nullus*." It will be observed that this work was published at Geneva the same year as that in which the Fire of London raged so terribly. In the second volume of Rudbeck's "*Campi Elysii*" (1701) thirteen species and varieties are figured. One of these, *F. polyanthos flavo-viridis*, resembles the Oxford one in point of shape more nearly than any other as yet met with, but the presence of the tessellated markings serves to terminate the comparison. In referring to this admirable work one cannot but be moved by feelings that are not easily expressed, for it furnishes a sorrowful incident in the annals of scientific research. It was the joint undertaking of Olaus Rudbeck and his son, both of whom in turn were professors of botany at

Upsal, and "it was one of the greatest undertakings of the kind" consisting of a collection of fine woodcuts of all the plants then known." These were to be arranged in twelve large folio volumes, but the second one had scarcely passed from the printer's hands when the work, together with many thousand wood engravings, intended for future volumes, were destroyed by a fire that laid almost the whole of Upsal in ashes. Grief for their loss is supposed to have occasioned the death of the elder Rudbeck in the same year. All that remains of this work are three copies of the first and six of the second volumes, one of each enriches the library of the Oxford Botanic Garden. — JOHN E. JEFFERIES, *Oxford*.

THE BULB MITE.

ALTHOUGH this troublesome pest is usually called the Eucharis mite, I think its name might be of a more general character, corresponding with its attacks. Various remedies have been advocated for its destruction, but I find nothing so effectual as watering with lime water. I quite agree with Mr. W. Simpson (page 558, last vol.) that it appears before decay takes place. The gravelly soil here is full of the mite. No matter which side of the estate I get it for potting purposes, it is there, ready to fasten on to the roots of any plants that are placed in it. Heat and moisture seem favourable for its development, consequently plants requiring much water are liable to suffer most. Lime water will cause the excrescence to decay that forms on the roots of Cucumbers, Melons, Tomatoes, Dwarf Beans, &c., without any apparent injury to the plants.

I had no idea till lately that this insect would injure hardwooded plants, but such I think is the case, as I have found evidence of it on Roses in the open, and on fruit trees. I am of opinion that it has something to do with the wart on the Vine. I had a lot of pot Vines started in the spring of last year that had been grown from eyes the previous season. They started strongly, and had grown about 18 inches to 2 feet, when I had them shifted into larger pots, using turfy loam and a little bone meal. In about a fortnight warts appeared, and the Vines stopped growing, or nearly so. Wondering whether my old enemy had anything to do with it, I examined the roots, and found the tissue eaten away, which made me conclude it was the mite. I at once applied my usual remedy, lime water, and the Vines partially recovered, but did not make such good canes as I had hoped to see. — T. E.

EVENTS OF THE WEEK.—The spring Show of the Richmond (Surrey) Horticultural Society will be held on Tuesday, March 18th, and the following day. The Croydon Gardeners' and Amateurs' Mutual Improvement Society will hold a meeting at 8 P.M. on the 18th inst., when a paper on "Hybridisation in Plants," by Mr. L. Castle will be read. The Royal Society meets to-day (Thursday) at 8 P.M., and the Society of Arts on Wednesday, March 19th, at 8 P.M.

— WE understand that good progress is being made with Baron Schröder's scheme for the establishment of a HORTICULTURAL HALL in LONDON. Donations of £1000 each are promised by Lord Revelstoke, Lord Rothschild, and Mr. Hambro, the new member of the Royal Horticultural Society's Council. The total amount already promised is nearly £7000, and we may expect that this sum will be rapidly increased as the merits of the scheme are made more widely known.

— THE BRITISH FRUIT GROWERS' ASSOCIATION held a Committee meeting in the Horticultural Club-room on Thursday, March 6th, at 5 P.M., Mr. T. F. Rivers in the chair, and amongst others present were Dr. Masters, Mr. Faunce de Launc, Mr. Bunyard, Mr. Wells Ingram, Mr. Goldsmith, Mr. Cummins, Mr. Butts, Mr. Gordon, Mr. Beach, Mr. Roupell, and the Honorary Secretary. The principal business was the election of local secretaries to represent the Association. Thirty members were thus appointed in Scotland, Ireland, Wales, and the following counties:—Hereford, Warwick, Worcester, Kent, Gloucester, Leicester, Sussex, Surrey, Essex, Middlesex, Cambridge, Somerset, Notts, Hants, York, Herts, Devon, Norfolk, Lancashire, and Shropshire. Arrangements were also made for a series of lectures in the North of England in response to inquiries. Affiliation with the Royal Horticultural and other societies was resolved upon, and other miscellaneous business was transacted.

— WILDSMITH MEMORIAL FUND.—We are pleased to receive a list of contributions to the Fund amounting to upwards of £40. W. J. Palmer, Esq., M.P. Messrs. Sutton & Sons, and Messrs. J. Veitch and Sons each contribute 5 guineas; the Hon. Emma L. Shaw Lefebvre £5; G. F. Wilson and Arthur Sutton, Esqs., each a guinea; while Miss Potts, Miss Markby, and Messrs. W. Binder, H. J. Clayton, W. Coleman, W. Crump, A. Dean, W. C. Davis, S. Kerry, A. Maxim, W. A. Searing, T. Turton, P. C. M. Veitch, and Messrs. Wood & Sons contribute various amounts. Mr. T. Turton, Maiden Erlegh Gardens, Reading, is the Honorary Secretary, and Mr. A. W. Sutton, Reading, and Mr. H. J. Veitch, Chelsea, the Honorary Treasurers of the Fund.

— THE WEATHER IN THE SOUTH has on several days during the past week been quite warm and springlike, with some rain, but on Sunday snow and hail fell at intervals, though the day generally was fine. Tuesday was exceptionally clear and warm, a great contrast with the previous week.

— THE WEATHER IN THE NORTH.—Changeable weather has marked the past week—3rd to the 10th inst. In the first two or three days high cold west winds prevailed. The 8th (Saturday) was an exceedingly unpleasant day, heavy sleety showers falling during the day and evening. During that night 9½° of frost were registered, followed by thaw and rain in the evening, and this morning (10th) at 10 A.M. the thermometer shows 45°. Heavy snow has fallen in the northern counties. — B. D. *March 10th, 1890.*

— CANKERED TREES.—A correspondent, "H. P.," desires to ask "G. C., *Warwick*" (page 202), to give the list of trees not fruit trees which he has found cankered. There is no doubt that there are several indigenous trees afflicted with the malady.

— WE are requested to draw attention to the sale of NEVILL COURT, which is advertised. Nevill Court is described as one of the finest residential estates in the Tunbridge Wells district, and the sale as an important one to horticulturists.

— ROYAL BOTANIC SOCIETY OF LONDON.—At a meeting of this Society, held last Saturday, Mr. J. Travers Smith in the chair, it was reported that included in the donations was a very interesting collection of seeds of economic and food plants, timber trees, &c., of Uruguay, presented by Consul Alex. K. Mackinnon. On the table were plants in flower of *Narcissus poeticus*, lately received from China, and several varieties of the same flower from the Scilly Isles, illustrating the cosmopolitan nature of this family of plants, which appears as happily at home in our native British fields and gardens as in China—in fact, in the Scilly Isles *Narcissi* are grown by the acre, and over ten tons of the flowers sent off weekly to market.

— ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 19th inst., at 7 P.M., the following papers will be read:—"A Brief Notice Respecting Photography in Relation in Meteorological Work," by G. M. Whipple, B.Sc., F.R.Met.Soc. "Application of Photography to Meteorological Phenomena," by William Marriott, F.R.Met.Soc. These papers will be illustrated with lantern slides. After the reading of these papers the meeting will be adjourned, in order to afford the Fellows and their friends an opportunity of inspecting the exhibition of instruments illustrating the application of photography to meteorology, and of such new instruments as have been invented and first constructed since the last exhibition. The exhibition will be open on Tuesday evening, the 18th inst., and remain open till Friday, the 21st inst.

— THE BELFAST GARDENERS' SOCIETY.—We have received the rules of this Society, which has been referred to as affording assistance to gardeners when out of situations. The conditions of membership are the payment of a fee of 2s. 6d. and 1s. a month afterwards. On the expiration of twenty-four months members out of situations are entitled to 10s. per week for eight weeks, and cannot, except by the decision of a specially summoned meeting, receive any further benefit for a period of two years. A six-years membership without interruption entitles the wife or family of each member to £6 at his death. The Society is registered under the Friendly Societies Act, and we are informed is in a flourishing condition, but we have no information respecting the number of its members nor the state of the finances, neither do we find the name and address of the Secretary appended to the rules. The meetings are stated to be held on the evening of the first Wednesday of each month in the Foresters' Hall, 44, Royal Avenue, Belfast.

— **HAARLEM BULB SHOW.**—The Quinquennial Exhibition of Hyacinths, Tulips, Narcissi, Armaryllis, and other bulbous and tuberous rooted plants will be open at Haarlem, Holland, on the 21st inst. and continued for five days.

— We are informed that MESSRS. SUTTON & SONS, READING, have adopted the electric light on a portion of their premises. Between fifty and sixty lamps have been in use for the past fortnight, and have been found satisfactory.

— **WAKEFIELD PAXTON SOCIETY.**—Rev. F. D. Horner is announced to read a paper before the members of the above Society on the 29th inst., entitled, an "Amateur's Experience with Orchids." It will, we suspect, attract a large attendance of members.

— **GARDENING APPOINTMENTS.**—Mr. Richard Morse, late of Clevedon Hall Gardens, has been appointed head gardener to D. A. Thomas, Esq., M.P., Llanwern Park, Newport, Mon. Mr. John Alex. Mercer, foreman at Childwall Hall, near Liverpool, has been appointed head gardener to Mrs. Kemp, Beechwood, Rochdale.

— **ECCLES AND DISTRICT CHRYSANTHEMUM SOCIETY.**—I beg to inform you that the Committee of the above Society has decided to hold their annual Chrysanthemum Show this year on November 14th and 15th at the Town Hall, Eccles, and I should be much obliged if you would bring this to the notice of your readers in the text of your valued paper.—H. HUBER, *Hon. Secretary*.

— **THE NEW ZEALAND INTERNATIONAL EXHIBITION.**—A newspaper report of the exhibits of Messrs. Sutton & Sons has been sent to us, but as our pages are full to overflowing we can only say that a show case of the firm containing their products is described the "most handsome in the Exhibition," and that the firm "secured seven of the highest prize medals at the Adelaide and seven highest awards at the Melbourne Exhibition."

— **THE WEATHER IN SUSSEX.**—March brought us in Mid-Sussex very wintry weather. There were 3 inches of snow on the morning of the 1st. A bitter N.E. wind prevailed, bringing showers of snow at intervals up till Monday morning at 8 A.M., when the snow was quite 8 inches deep. On Monday and Tuesday the sun was quite hot, but it seemed to have as little effect on the snow as a December sun. Thermometer readings:—Morning of 1st, 22°; 2nd, 24°; 3rd, 18°; 4th, 13°.—R. INGLIS.

— **EARLY RHUBARB.**—The Rev. W. H. Sewell writes from Yaxley, Suffolk:—"I shall be happy to show any of your readers my dwarf Rhubarb, wholly unforced, as it is now growing in the open in my garden, requesting only a letter or postcard making an appointment, any day but Sunday. As the winter was so mild, the Rhubarb this year was somewhat later than usual, St. Valentine's Day. The first good gathering was on February 22nd. Since then it has been, and is, being pulled as required. Should this note fall under the eye of any of the persons to whom, last autumn, I supplied roots, I should like again to urge them (even professional gardeners) to please to follow the cultural directions sent, which an experience of several years has proved to be important."

— **SPRING SHOW AT WESTMINSTER.**—The first of the series of Shows announced to be held in the Royal Aquarium, Westminster, was opened on Wednesday last, March 12th, and proved to be most successful both in number and quality of exhibits. We regret that this week we can only give a cursory review of the character of one of the best spring Shows yet held at so early a date in the season. Classes with liberal prizes were provided for bulbs, forced plants, Daffodils, Cyclamens, Primroses, besides miscellaneous groups of plants, and the entries were numerous. The plants were tastefully and effectively arranged by the Superintendent Mr. W. Holmes, who may be congratulated on the results of the first of the Shows under his management. Some of the principal exhibitors were Messrs. J. Laing & Sons, H. Williams & Sons, T. S. Ware, J. Turk, W. Clarke, Barr & Son, Collins Bros. & Gabriel, D. Phillips, J. Odell, C. Nunn, B. S. Williams & Son, J. Cheal & Son, and R. Dean.

— ON the 5th instant thirty of the foremen and clerks of the firm of MESSRS. RICHARD SMITH & CO., ST. JOHN'S NURSERIES, WORCESTER, were entertained at dinner by Mr. Smith Carington, the senior partner, in commemoration of his mayoralty of the Faithful City this year. The company sat down to an excellent repast, and after doing ample justice to a liberal bill of fare the rest of the evening was spent in speech making, songs and music. The healths of His Worship

and of Mr. R. C. S. Carington, the managing partner of the firm, were proposed in eulogistic terms, and suitably responded to by both gentlemen. Altogether a most enjoyable evening was spent, the company separating at 11 o'clock with hearty good wishes for the continued prosperity of the firm. We are always glad to hear of these pleasant reunions, which tend to strengthen the bonds of sympathy between employer and employed.

— **A GREAT HORTICULTURAL EXHIBITION** will be held in the Pavillion de la Ville, Champs Elysées, Paris, in May, opening on the 21st and closing on the 26th. It is intended to be a general exhibition of the products of horticulture, and of objects of art and industry employed in gardening or serving in the decoration of parks and gardens. The classes number upwards of 200, and embrace new plants, stove, greenhouse, and hardy plants, Ferns, Palms, Orchids, cut flowers, fruit, vegetables, and garden implements, amongst others. Prizes of honour, gold, silver-gilt, silver and bronze medals will be awarded. The Exhibition will be under the auspices of the French National Horticultural Society, and inquiries must be addressed to the President of the Society, Rue de Grenelle, 84, Paris, before Thursday, May 15th. Exhibits will be received from the fifth to the second day before the opening, not later, except in the case of cut flowers, which will be received up to 7 A.M. on the morning of the Show.

— **NICOTIANA AFFINIS FOR CONSERVATORY AND DRAWING-ROOM DECORATION.**—I notice in the *Journal of Horticulture*, March 6th, page 197 that Mr. Murphy highly commends the above-named, and rightly too, for I find it invaluable. I have grown it for several years, and we are seldom without plants in flower; indeed, I have received orders to try and keep it in bloom always. I cannot recollect having a break for eighteen months. Seed is cheap, and it is so easily raised that I do not find it difficult to keep a supply of young plants, and it will grow as freely from the root as from seed; broken up every little piece will grow and form a plant if put in a pan and placed in a propagating frame. It is useless to keep old plants after the first time of flowering. Young plants grow quickly, and produce much finer blooms. They will grow in almost any soil, but they pay well for liberal treatment. Loam, leaf soil, and manure in equal parts with the addition of a little sand suits them admirably, and they are benefited if liquid manure can be given when the pots are full of roots. They are water-loving plants, as they like plenty at the roots and over the foliage in hot weather. The best results are obtained from plants repotted from time to time until they are in 8 or 10-inch pots. The cultivators will then have good plants self-supporting, with stout flowering shoots from the axils of every leaf, and foliage completely overing the pots.—W. SPENCER, *Southport*.

— **AMERICAN APPLES.**—Apples command high prices. Hard Maine Baldwins are worth 3 dollars 75 cents, to 4 dollars per barrel, and other New England Baldwins command 2 dollars 50 cents, to 3 dollars 50 cents. There is a feeling among some of the trade that prices are almost too high. The buyers of Apples to sell again complain that there is no margin in handling them. Nevertheless, the country is very firm on the few that are not picked up. The request for export is only fair, prices being too high for a liberal movement through that channel. In New York lighter arrivals and a fair demand have combined to make a firmer market. Sales have been mainly in the range of our market quotations, but here and there an exceptionally fancy lot of Greening or Baldwin is placed a little above outside figures. The export of Apples from all American ports for the week ending February 19th, as reported by A. C. Lombard's Sons, were 18,594 barrels, including 1,336 barrels from Boston, 2,838 barrels from New York, 7,420 barrels from Portland, and 7,000 barrels from Annapolis. For the season the total exports have been 637,481 barrels, including 131,186 barrels from Boston, 133,505 barrels from New York, 162,526 from Montreal, 103,324 barrels from Portland, 44,930 barrels from Halifax, 37,010 barrels from Annapolis. For the same time last year the total exports were 1,209,548 barrels, including 351,840 from Boston, 411,082 from Montreal, 84,771 from Portland, 70,160 from Halifax. Boston's week's shipments were 1,330 barrels to Liverpool. Of the week's foreign export of Apples, 11,096 went to Liverpool, 415 to Glasgow, and 7,983 to London.—(*American Cultivator*.)

— IN the "BOTANICAL MAGAZINE" FOR MARCH the plants figured are as follows:—*Zamia Wallisi* (t. 7103) is "one of the three new species discovered in 1873 by Gustav Wallis when in the employment of Messrs. Veitch as collector in New Grenada." The leaves are 2 to 3 feet high, with two to eight pairs of leaflets, specimens of the

latter, 17 to 20 inches long, and 4 to 10½ inches wide, being preserved. *Satyrion membranaceum* is a South African Orchid related to *S. carneum*, and found in "the same kind of wet sandy dunes near Cape Town." The flowers are bright rosy red, much like those of *S. carneum* roscum figured in this Journal. *Arisæma Wrayi* (t. 7105) is a tropical Aroid found "in Perak, where it was discovered by Mr. L. Wray." The spathe is pale green, with a long narrow drooping spadix, the leaves are pedate, with five to nine narrow divisions. *Lathræa clandestina* is one of the remarkable Toothworts found in the west and south of France, in Spain, Belgium, and Italy. "A plant was presented to Kew by Dr. Schumann in May, 1888, and was planted by the roots of a Willow near the piece of water opposite the museum No. 1, and flowered in April 1889." The flowers are pale purple with a darker lower lip. *Papaver rupifragum* var. *atlanticum* (t. 7107) is a native of Morocco discovered by Mr. Ball and Sir Joseph Hooker at an elevation of 6000 to 7000 feet in the Greater Atlas south of the city of Morocco, growing in dry rocky places. It is a perennial, and bears large bright orange red or scarlet flowers.

— EMIGRATION OF GARDENERS.—Perhaps it may interest Mr A. Outram to learn that the gardener who sailed on January 4th in the "Wyoming" for America arrived "four days overdue." "We experienced," writes our prompter of the notes that you, Mr. Editor, have found a place for in the *Journal of Horticulture*, "very severe weather, and for about four hours the waves were so high we expected to go down. We lost three boats, one of which was stove in, breaking it into match-wood; the other two were lifted clean away. One sailor was washed overboard, but was recovered. I landed on 18th January at Castle Gardens, New York. Not many passengers; five not having money or friends, will be sent back, and an elderly man was taken by a detective just as he was leaving the boat, being wanted in London. The weather is very mild for the time of year." The above under date of January 20th. Writing again from Holmsburg, Philadelphia, G.A., U.S.A., February 10th, "I have been to all florists worth working for. They promised work as soon as the weather permitted, but sorry they had no opening at present. They also told me that there was an unusual number of good men out this year, and advised me not to depend too much on the florist. So being disappointed for once, and as you are aware my funds are only small, I have taken advantage of the St George's Society, of which I am a member. They take all poor members in during the winter months, finding them sleeping apartments and plenty to eat." This is given for the perusal of "B.," who will see that what he proposes is done in America, and is a success. Continuing our extract, "Usually in January there is plenty of ice cutting, which lasts six weeks, and passes over the worst part of the winter. None had yet. This will be felt very much in the summer, as everybody uses ice, but the prophets say there will be plenty, and you know the Yankee is great on weather predictions. Everything here is very forward; grass long enough to cut with a machine, most trees ready to burst, Roses with shoots 2 inches long, more like the middle of April. The papers give it out as the mildest winter for over 125 years. Farmers are already going crazy owing to the earliness of crops. They say if wintry weather does come they will be ruined."—UTILITARIAN.

— THE annual meeting of the members of the TWICKENHAM HORTICULTURAL SOCIETY was held recently in the Town Hall, the Rev. D. Anderson presiding. The Hon. Sec. announced that the Sub-Committee appointed to consider the question of the advisability of amalgamating with the Teddington Society had conferred with the Sub-Committee of that Society. A report was made to the General Committee at Teddington, and after considerable discussion it was resolved that the time had not arrived when the amalgamation of the two Societies would be desirable. In the twenty-first annual report, which was read by Mr. J. G. G. Pugh, the Hon. Sec., the Committee tendered their best thanks to the subscribers and exhibitors for their co-operation and support. The report stated that it was matter for regret that the summer Show did not pay financially, and last year a deficit of £32 15s. occurred, this, however, being reduced by donations amounting to £10 16s. 6d. It would be the duty of the Committee to reduce the prizes in the schedule for the forthcoming summer Show in such a manner as would meet the altered circumstances of the subscription list. The autumn Show still increased in popularity, and out of 260 entries upwards of 100 were those of cottagers. The receipts of the Show were £101 19s., and the profit of £11 9s. 1d. went in reduction of the deficit on the summer Show. In conclusion the Committee thanked Mr. J. S. Nicholson for the use of Poulett Lodge for the summer Show, Lady Freake for the use of the Town Hall in the autumn, and all

those who had assisted during the year. An addition to the rules to the effect that all objections should be made in writing to the Secretary before four o'clock on the day of the Show was carried. Mr. Bates proposed that eight tickets only be given to each subscriber, except on application to the Secretary, and in support of his motion he stated that in many cases one subscriber received sixteen tickets, which was ridiculous in his opinion. The Secretary stated that under the present system 1200 tickets were issued, thirty-two being sent to one subscriber in one case; that the adoption of the proposition would lessen the expenses, and would no doubt benefit the Society. The motion was agreed to. Mr. Pugh was re-elected Hon. Sec., Mr. Roe Treasurer, and Messrs. Duncan and Bates Auditors, votes of thanks being accorded to each for past services. The Committee was then re-elected, Messrs. Bruckhause, Walde, Sage, and Mitchell being elected to fill vacancies. It was decided to hold the summer Show on July 2nd.

— THE *Kew Bulletin* for March contains chapters on the origin and production of "Indian Yellow," "The Commercial Value of Loxa Bark" (*Cinchona officinalis*), and "Barilla" (*Halogeton sativus*). Respecting the last named much interesting information is given, and we extract the following, by Mr. Jasper W. Cumming, Vice-Consul, Alicante:—

— REPORT ON THE BARILLA INDUSTRY (*Salsola* or *Halogeton sativus*).—"Since the development of the manufacture of soda salts by purely chemical processes, the Barilla industry in this province has become very reduced, although not completely obsolete, the plant being still cultivated to a certain extent. It is very difficult to ascertain the quantity of Barilla manufactured, but I am informed that from 200 to 250 tons may be considered an average yearly production. Value varies greatly according to abundance and demand, and may be roughly quoted from 2 dols. to 2½ dols. per quintal or 50 kilos. As to the cultivation of the plant, the seed is sown in January and February in the same manner as other ordinary seeds, and requires no special care. The seed becomes worthless if not sown the season following its collection. The plant is gathered in August. It is pulled up by the root, spread for two or three days, and then collected in small conical shaped piles of two or three quintals each, so that in case of rain the water may not penetrate so much into the interior and rot the plant. It is left thus about a month to thoroughly dry. If not then required to be burnt it is stacked and covered with esparto or rush to preserve it. The manufacture of Barilla is carried out as follows:—A hole is dug out in the form of a large round earthenware pot, about 1½ foot in diameter at the mouth, about 4 feet at the bottom, and depth about 3½ feet, the inner part of which is well beaten, and then covered with a slight smooth coating of mud. A small quantity of wood is then burnt to ashes in this hole to dry and heat it, when it is cleaned out and a couple of iron rods or bars are placed across the mouth, over which bars a quantity of the plant is placed and fired, more being added continually as it is consumed for about twelve hours. Then the bars are removed by means of a large, bent, two-prodded, wooden fork, the boiling substance in the hole is thoroughly stirred, till it becomes even and smooth on surface like molten lead; then the bars are replaced, and the same operation repeated until the hole is filled, when the entire mass is finally stirred as described. The mouth of the hole is then closed up, and the Barilla is left about a week to cool thoroughly, during which time it hardens and cracks into pieces. The hole has then merely to be dug around and the Barilla taken out."

TREATMENT OF MANURES.

IF Mr. Tonks, on page 192, considers my remarks on page 172 "rancorous," he is free to indulge in such epithets, but I prefer to discuss matters on which differences of opinion exist in a spirit of impartiality. I have carefully gathered all the evidence I can, and this supplemented by my own experience, I intend placing under the heading of "Artificial Manures; their Uses and Abuses." This, I hope, will give Mr. Tonks sufficient food to digest and subject matter for criticism, as some facts therein may be antagonistic to his ideas. The subject will embrace the natures of soils, their origin, constituents, and deficiencies; the crops they will suit or not suit, and how they can be made suitable to any crop; the various manures, artificial or natural, that ought to be applied, the effect and the various reactions that take place upon their application to the soil and upon crops or plants; therefore I will not discuss Mr. Tonks' letter as I would otherwise have done. I was only struck by the manufacturer utilising his farmyard manure because of the great expense of the application of 10 tons of it, if a cwt. of properly prepared artificial mixture would have supplied all that was necessary.

Knowing that there are persons still ignorant enough to believe that the canker and all other diseases affecting tree life is caused by the

bark being punctured by some insect, it is not surprising to see others still believe in the blight being caused by dull foggy weather. I do not belong to those, but knowing that foggy weather is favourable to their increase, I have avoided calling those ignorant who did not take the trouble to find out the origin of the American blight. My knowledge as to various diseases being caused by artificial mixtures do not come from such vagaries, but until Mr. Tonks is able to give the origin of the various fungi I do not consider he is justified in placing my opinion at a discount. The Potato and Hop diseases having followed in the rear of the artificial manure era, justifies anyone in considering the connection. I am prepared to hear soon of the creation of Chrysanthemum

At the Chrysanthemum centenary celebration, held by the Royal Horticultural Society at Chiswick on November 5th last year, a few other plants of interest were exhibited, and among them was *Vriesia Marie*, a hybrid from M. Truffaut of Versailles. The plant is depicted in fig. 30, which shows its characters well, the scape, bracts, and flowers being bright red and greenish yellow, spotted with reddish brown. Like the other *Vriesias*, it is easily grown, but requires a warm house and plenty of moisture, both in the atmosphere and at the roots.

FIG. 30.—*VRIESIA MARIE*.

disease; the damping of the blooms has already been attributed to artificial manures. Mr. Tonks mistakes me if he thinks I include pure Peruvian guano under that heading, for it is a natural manure, though there is greater danger in its application than in the use of stable manure.—G. A. BISHOP.

VRIESIA MARIE.

BROMELIACEOUS plants are not such general favourites in England as they are on the Continent, and few nurseries here contain a collection, or even a few species, while in France and Belgium the majority include a large representative number of the most attractive forms. Some attention has also been paid to hybridising them, and from time to time we hear of fresh additions being made in this way, but seldom see them except in botanic gardens. The Kew collection is especially rich in species and varieties, many having been added from the great collection formed at Liège by the late Professor Morren.

PLANTING FOR EFFECT.

MUCH may be done in the grounds attached to the majority of country mansions to render them more interesting and picturesque than they are at present at a trifling expenditure. Pleasant surprises should be experienced in every nook and turning of the grounds and carriage drives, and the wilder and more natural they are in appearance in certain parts the better will be the effect. In the construction of hardy ferneries, undulated and rugged surfaces and irregular outlines should be observed. Rough stones, burrs from the brick-kilns, clinkers, roots, butts, and gnarly portions of trees, together with any old figures that may be at hand, are the most suitable materials. When the logs and butts of trees, with the roots sticking upwards, are placed in position, the intervening spaces should be partly filled with light soil before placing the stones, burrs, and clinkers irregularly over the surface, afterwards partly filling the interstices with soil. Leaf mould liberally intermixed with ordinary garden soil will suit the require-

ments of the majority of the Ferns. Any time within the next six weeks or so will be suitable for lifting and transplanting Ferns. In planting make the soil firm about the roots, and then give sufficient water to settle it down. A knowledge of the characters of the British Ferns will greatly assist in their proper disposition when planting. After the Ferns are planted sufficient Ground Ivy and Periwinkles should be set to cover the bare roots and stones after the Fern fronds have died down during the winter and early spring months.

Old bare-stemmed trees, which are situate within view of frequented walks and drives, instead of being cut down may be rendered objects of beauty by clothing them with healthy flowering shoots of Evergreen Honeysuckle, Virginian Creepers, and blue and white Clematis, depending therefrom in wild profusion.

Tripods consisting of young trees thinned out of plantations of Fir with the branches cut off at irregular distances of 5, 7 to 15 inches from the main stem, fixed here and there in isolated patches of greensward, may be covered with such Roses as the white and yellow Banksian, Donna Maria, pure white; Felicité Perpetue, creamy white; Banksiaefolia, white and buff; Princess Louise, light pink; Alice Gray, creamy blush; and Queen of the Belgians, pure white, cupped and double. Thus furnished, with the flowering shoots tied quite loosely to the horns of the Fir poles, floral objects, lending variety and charm to their surroundings, are secured. Masses of the Japanese Rosa rugosa planted near to walks and drives are, by reason of its luxuriant and handsome foliage and single flowers, which are succeeded annually by a profusion of large bright reds hips, very effective, as also are similarly planted masses of Bramble. Rubus laciniatus is suitable for this purpose. Patches of the single and double flowered Furze are also telling. Standard Rhododendrons of R. guttatum and other good light varieties carpeted with the pink flowered and fragrant Daphne Cneorum are strikingly beautiful, the peaty soil in which the Rhododendrons delight being equally congenial to the requirements of this trailing and free-flowering Daphne.

In the laying out of pleasure grounds due provision should be made for planting numbers of the several beautiful species of coniferous ornamental trees and shrubs, including a large per-centum of flowering varieties, both as specimens and groups. A few plants of the Florida Allspice (Calycanthus floridus), Chimonanthus fragrans, Lilac, Philadelphus (commonly called "Mock Orange" and Syringa), Skimmia japonica, Sweet Briar, together with Wall-flowers and Violets, should be freely planted. Masses of Snowdrops, Primroses, Daffodils, Blue Bells, and Forget-me-nots, should also be planted freely within sight of shrubbery walks and carriage drives. Take advantage of rivers running through the ornamental grounds and park to plant on its banks standard trees of Weeping Birch (Betula pendula), Laburnum, Willows (Salix babylonica and S. pendula), Mountain Ash, and Golden Elder (Sambucus nigra aurea). In planting see that the trees do not in any way interfere with the view of objects of interest from any particular standpoint. Work such as referred to in the foregoing general remarks may be done at any time (weather permitting) between October and April, but the sooner it is done before the latter date the better it will be for those transplanted.—H. W. WARD, *Longford Castle, Salisbury.*

NOTES ON FRUIT TREES—APPLES.

(Continued from page 195.)

OF dessert Apples many, though of the highest excellence, are too small for appreciation by the general public, and though some are useful for culinary as well as dessert use, they are not valued in the kitchen, through the skin and core being in relative excess of the flesh in the small fruit as compared with the medium or larger sized fruit. This necessitates keeping two descriptions of fruit—viz., one for dessert and the other for culinary use, which in moderate establishments is more or less inconvenient, and with the general public still more so, as means are not available for investing in both, yet an Apple is liked uncooked as well as cooked. Therefore advantage is gained by having varieties possessing both properties.

DESSERT VARIETIES.

Early.—Irish Peach; medium, yellowish green, tinged reddish brown, brighter on sun side, beautiful, flesh tender, free bearer. August and September. Kerry Pippin; rather small, greenish yellow tinged and streaked red, bright crimson on sun side, flesh firm, a good bearer. September and October. Duchess of Oldenburg; large or medium, greenish yellow, streaked, good bearer. September. Midseason.—Golden Winter Pearmain or King of the Pippins; medium, golden yellow, streaked and mottled crimson, very handsome, flesh firm, free bearer, and certainer than most. October to December. Cox's Orange Pippin; medium, greenish yellow, dark

red on sun side, handsome, flesh tender, free bearer. October to January. Cackle's Pippin, medium; greenish yellow becoming brighter when mature, dotted grey, and somewhat russety flesh, firm, moderate cropper but certain. December to February. Fearn's Pippin; medium, but often small, greenish yellow, bright dark crimson on sun side, pale streaked on shaded side, very pretty, flesh firm, good cropper. November to February. Golden Reinette; medium, deep yellow, tinged on sun side with red, very handsome, flesh firm, good bearer, but requires a well drained soil and warm situation. November to February. Claygate Pearmain; medium, greenish yellow, striped red on sun side, slightly russety, flesh firm, free bearer. November to February. Adams' Pearmain; large or medium, greenish yellow, tinged red on sun side, slightly russeted, handsome, good bearer. December and January. Margil; medium or slightly below, orange, streaked red, russety, flesh firm, good bearer, but not a free grower, and requires a well drained soil and sheltered situation. November to February. Mabbott's Pearmain; medium, orange yellow, streaked red, handsome, flesh rather tender, good bearer. November to February.

Of early autumn varieties, American Mother, medium or above, golden yellow, patched and streaked crimson, russety, handsome, flesh tender, moderate bearer, October and November, and Melon Apple, large or medium, orange yellow, streaked crimson, handsome, flesh tender, December and January, are American varieties of the first order, which do not succeed on strong loam over clay, but require a silicious loam over sand, or a loam medium or clayey interspersed with calcareous gravel, on sand or gravel, and given shelter they are fine.

Late.—Boston Russet; medium, brownish yellow russet intermixed with green, flesh moderately firm, good bearer, but not a good grower, and though an American variety attains perfection in most soils and situations. January to April. Court Pendt Plat; medium, yellow, deep crimson on sun side, handsome, flesh firm, good bearer but not a strong grower. January to May. Stamford Pippin; medium, greenish yellow, tinged orange on sun side, good bearer, flesh firm but not hard, having a crisp tenderness when ripe. December to March. Golden Russet; medium, brown yellowish russet, and in good examples brown red on sun side, flesh firm but melting, good bearer. December to April. In silicious loams of good depth with sand or gravel under, this variety does well, but in cold heavy soils it does indifferently. In some years I have known the fruit bring 5s. per peck. All russety Apples require care in keeping; if exposed to light and dryness they shrivel, requiring to be kept cool yet safe from frost, dark and dampish, then the fruit comes out quite plump, and remarkably bright in colour, with a juiciness not found in those kept otherwise. Rhode Island Greening; large or medium, pale green, flesh rather firm but melting, good bearer. November to April. This is another of the American Apples, and good alike for eating or cooking, but it does not succeed in cold heavy soils and exposed situations. In good soils and sheltered positions it is first rate both in cropping and using. Allen's Everlasting; medium, crimson on sun side, pale on shaded, flesh firm, but tender in matured examples. March to May. Scarlet Nonpareil; medium, handsome, good bearer, January to March. I have omitted Ribston Pippin and Lord Burghley, as they are too subject to canker for general culture, and many others are omitted on account of their small fruit. Of those named for dessert purposes some have great value for cooking, and as such are calculated to meet general acceptance. Such are Duchess of Oldenburg, King of the Pippins, Fearn's Pippin, Adams' Pearmain, Stamford Pippin, Rhode Island Greening, and Allen's Everlasting.

Passing on to culinary varieties, we find little to be wished for, indeed, in their respect, we come quite up to the American standard in size.

KITCHEN VARIETIES.

Early.—Keswick Codlin; large or medium, pale yellow, brighter and deeper on one side with a faint blush, flesh soft, free bearer, may be used when large enough, best in August and September. Royal Codlin; large, greenish yellow, flushed red, handsome, flesh tender, good bearer. September and October. Cellini; large or medium, greenish yellow, red streaked and mottled, showy and handsome, flesh tender, capital bearer. October and November. Lord Grosvenor, large, greenish or pale yellow, very fine, flesh tender, free bearer. September and October. Lord Suffield, large, pale yellow, very fine, flesh soft, early and great cropper. August to October. Potts' Seedling; large, greenish yellow, flesh soft, early and great bearer. September and October. Ecklinville Seedling; large, greenish yellow, handsome, flesh soft, good bearer. October and November. Stirling Castle; large or medium, greenish yellow, flesh soft, early and very free cropper. September and October.

Midseason.—Alfriston; large, greenish yellow, tinged orange on sun side, somewhat russeted, flesh firm, moderate bearer. November

to February. Beauty of Kent; large, yellow, red on sun side, flesh tender, good bearer. October to January. Bedfordshire Foundling, large, greenish yellow, tinged orange on sun side, handsome, flesh tender, good bearer in silicious soils. November to February. Betty Geeson; large, greenish yellow flushed on sun side with blush, flesh tender, early and great bearer. November to March. Emperor Alexander; large, greenish yellow, orange, streaked bright red on sun side, noble and beautiful, flesh soft, free bearer. October to December. Golden Noble; large, bright yellow, very handsome, flesh firm, but tender though solid, great cropper. October to December. Grenadier; large, greenish yellow, handsome, flesh tender, good bearer. October and November. Hollandbury; large, yellow, deep red on sun side, a very handsome showy sort, flesh soft moderate cropper. October to December. Hornead's Pearmain; large or medium, greenish yellow, somewhat russety, very handsome, flesh tender, moderate cropper. November to February. Lord Derby; large, greenish yellow, handsome, flesh tender, great cropper. November and December. Nelson Codlin; large, greenish yellow, brighter on sun side, flesh tender, good bearer. October to December. Peasgood's Nonesuch; large, yellow, flushed and streaked red, handsome, flesh soft, free bearing. October and November. Round Winter Nonesuch; large, pale yellow, streaked and spotted crimson, fine and handsome, flesh tender, good bearer. November to December or January. Royal Russet; large, brown russet, reddish on sun side, flesh soft, free bearer. November to March. Unless kept from air and light, and cool and moist, it shrivels and is worthless. Small's Admirable; medium, greenish or lemon yellow, flesh rather firm, free bearer. November and December. The Queen; large, greenish yellow streaked crimson, very handsome, flesh soft. November and December. Loddington; large, green, flushed red, flesh firm, handsome, good bearer. November and December. The Sandringham; large, yellow and shining, striped and flushed red on sun side, very handsome, flesh tender, good bearer in a young state, in which only have I seen it. November to February or March. Castle Major; large, yellow, flushed red, very handsome, flesh tender, moderate cropper. October and November. Tower of Glamis; large, greenish yellow, flushed red, handsome, flesh rather firm, good cropper. November to January. Waltham Abbey Seedling; large, pale yellow, flesh soft, free bearer. October to December. Warner's King; large, greenish yellow, patches and dots of delicate brown russet, imposing in appearance, flesh soft, good bearer. November and December. Welford Park Nonesuch; large, lemon, bright crimson on sun side, streaked darker, handsome, flesh soft, good bearer. October and November. Melrose; large, yellow, tinged orange and crimson, spotted on sun side, handsome, flesh soft. October and November. Greenup's Pippin or Yorkshire Beauty; large, orange yellow, flushed bright red, handsome, flesh tender, great cropper. October and November. Yorkshire Greening; large, green, streaked red, flesh rather firm, good bearer. October to January. I have omitted the Hawthorndens as I find the fruit "pit" badly, and in most instances worthless on that account.

Late.—Annie Elizabeth; large, pale or greenish yellow, spotted and streaked crimson, flesh firm, good cropper. January to April. Bramley's Seedling; large, green, streaked red, flesh firm, strong grower and free bearer. January to March. Dumelow's Seedling; large or medium, pale yellow, pale red on sun side, sometimes bright red, flesh firm, greater bearer. November to March. Flanders Pippin; large or medium, green or greenish yellow, dull red on sun side, streaked, handsome, flesh tender, good cropper. December and January, or later. Galloway Pippin; large or medium, pale yellow, pale red on sun side, handsome, flesh firm, good cropper. November to January. Gooseberry Apple or Pippin; large or medium, green, red next sun, flesh firm, good bearer. November to May. Hambledon Deux Ans; large, greenish yellow and dull red, streaked on sun side, flesh firm, good bearer. January to May. Hanwell Souring; large or medium, greenish yellow, slightly flushed red on sun side, flesh firm, good bearer. December to March. Lane's Prince Albert; large, pale green, flushed and streaked red, flesh tender; a handsome Apple after Cellini type, and a very free bearer. December to March. Minchall Crab; large or medium, yellow, pale crimson in streaks on sun side, flesh firm, good bearer. November to March. Norfolk Beefing; medium, greenish yellow, covered with dull brownish red, flesh firm, good bearer, but does not succeed in cold wet soils. January to May. Northern Greening; medium, green, brownish red on sun side, slightly streaked, flesh firm, good bearer. December to April. Rymer; large or medium, greenish yellow, streaked and flushed red, flesh firm, good cropper. November to March. Some of the kitchen varieties have value for the dessert, alike from noble appearance, juiciness, tenderness of flesh, and briskness of flavour, as Peasgood's Nonesuch, Yorkshire Beauty, Emperor Alexander, Lord Derby, Melrose, Nelson Codlin, Small's Admirable, Hornead's Pearmain, and Hambledon Deux Ans.

Altogether eighty-nine varieties have been briefly described—viz., twenty-three sorts as suitable for kitchen and dessert, of whose quality for both purposes there is no question, and if to those be added the kinds which, though having greatest value as dessert or kitchen varieties—viz., nine of each—the number is brought up to forty-one. We want varieties that are staid, fair and taking in looks, flat and pleasing in quality. Brandy Apple, Golden Knob, and Golden Pippin, delicious as they are, are inadequate to the requirements of boys who make no account of skin and core. Ribston Pippin that cankers its life away, or Hawthornden that pits off its good looks, neither satisfy the old gentleman nor please the cook. No, the colonists of America have shown us that there are wants to be met other than luxurious fancies—indeed fruit must be "a delight to the eyes and good for food"—a combination of ornament with utility, the measure of its appreciation depending on its usefulness and economic value. Variety is not considered in food supplies of Apples. That is most highly prized that offers the most and is enjoyed the longest. Therefore the Americans with not more than half a dozen varieties are able to transport fruit profitably to our markets. Evolution in Apples truly has advanced. 1545 varieties are described in "British Apples" as "presumably distinct," but there has been so little selection that the American Apples represented by the units have given the hundreds their quietus, and scared the home growers "out of their wits."—G. ABBEY.

(To be continued.)

A CHRYSANTHEMUM DINNER.

THE members of the Sheffield and Hallamshire and the Sheffield and West Riding Chrysanthemum Societies, which have now been amalgamated under the title of the Sheffield, Hallamshire, and West Riding United Chrysanthemum Society, held their annual dinner on Thursday evening, March 6th, at the Maunche Hotel, where, after full justice had been done to an ample repast provided by the manager, Mr. W. Ross Cattanagh, the chair was taken by T. B. Hague, Esq.

The Secretary having read letters of apology from the President, Mark Firth, Esq., Archdeacon Blakeney, and other patrons, the Chairman proposed the usual patriotic and loyal toasts. Mr. G. S. Stocks then proposed the toast of the evening—"The United Society," and in a neat and very effective speech alluded to the great advantages which would certainly accrue from amalgamation; the jealousy which had existed previously would be now swept away, and professionals and amateurs would now look for one common object—the successful cultivation of the flower, and the success of the annual Exhibition.

Mr. E. D. Smith, in proposing "The Officers of the Society," trusted that as heretofore they would work well and effectively. The Secretary in replying stated that he thought as at present officered failure was out of the question, as everything had been so thoroughly in unison, such unison must tend to ultimately achieve the most thorough success. Mr. Newsham proposed "The President, Vice-President, and Patrons," which was responded to on their behalf by Mr. Collier; the rest of the evening being devoted to harmony, Messrs. Cattanagh, F. Lawton, Edge, Jarvis, Padley, Housley, and others contributing, and a pleasant evening came only too quickly to a close.

The annual Show is fixed for the 14th and 15th of November, and schedules will be ready as early as practicable, due notice of which will be given in the horticultural press.

THE KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY.

THE Society named above is entering upon the fifteenth year of its existence, and from the time of its formation its finances have been looked after by one gentleman—Mr. John Drewett—who is known to many as being connected with sundry and divers public institutions in the town. With him was associated nearly twelve years as Honorary Secretary the late Mr. Thomas Jackson; and it is a fact that the Society would have come to an end about five years ago, owing to the financial depression, had they not made up their minds to one more effort, which was attended with success. On the death of Mr. Jackson his colleague wished to be relieved of the duties of the office of Treasurer, but was induced to continue them by the prospect of finding a worthy successor to the late Secretary in the person of Mr. George Woodgate, and by the promise of support from several amateurs, among whom may be mentioned Alderman Sherrard, Messrs. Furrz, Douet, F. J. Hayward, and Dr. Walker of Wimbledon. The tide of prosperity now seems to have set again in favour of the Kingston and Surbiton Chrysanthemum Society, for after putting £40 to the reserve fund there is a balance of £23 still in hand.

Out of the feeling that to Mr. J. Drewett was due in a high degree the survival of the Society through most adverse circumstances, came a

desire to testify to him how his past services are valued, and at the request of the Committee Mr. Woodgate made known that wish to some of the oldest supporters of the Society, but no general appeal was made, in order that what was being done should be kept strictly private, as was the case. In a short time subscriptions to the amount of nearly £36 were received, and the presentation decided on consisted of a gold watch, a "Tantalus" stand for the sideboard, and an inscription on vellum. The two articles first named bore inscriptions setting forth why they were given, and on the vellum the same was stated, with the subscribers' names appended. This last, which was mounted and framed, was quite an artistic production, and in the bordering was introduced a faithful representation of the flower which gives its name to the Society under notice. It was designed and executed by Mr. E. Woodhouse, at 37, Market Place, Kingston.

The presentation was made last Saturday evening at the "Kingston Hotel," in the presence of about thirty out of the forty-five subscribers to the testimonial, amongst whom were all the lady patronesses and Sir Whittaker Ellis. The last named had hoped to be present on the occasion, but was not able to compass it. Following the usual custom there was first a sitting around the "board," which was well spread, but not extravagantly, and among the two dozen present at that function were several who assisted at the birth of the Kingston and Surbiton Chrysanthemum Society, and still take an interest in its welfare. G. C. Sherrard, Esq., J.P., the President of the Society, was the Chairman of the evening, and on behalf of the donors he made the presentation most gracefully, and the recipient of the gifts acknowledged them very feelingly.—(*Kingston and Surbiton News*.)

LANDSCAPE GARDENING.

[Read at a meeting of the Cardiff Gardeners' Association by Mr. Kettlewell.]

LANDSCAPE gardening is the highest branch of the art of gardening, inasmuch as the materials with which a landscape gardener works include all the noblest features of the country. It has respect to small plots as well as large and extended tracts of land—from half an acre attached to a villa residence, as well as to 20 or 100 acres attached to a mansion, and reaching out to a large park. It differs from ordinary gardening or forestry, inasmuch as it relates more to the first laying out of the land, to the arrangement and the adaptation of it, so as to set it forth to the best advantage, which the gardener or forester is afterwards to keep in order. Taking the art of landscape gardening generally there seem to me to be three most important features which will make or mar the picture, and it is in these that we discern the talent and taste and ability of the true landscape gardener. These three features are—1, The grouping and arranging of trees or shrubs, whether singly or in masses. 2, The undulating of the ground where necessary. 3, The finishing off of the whole. With reference to the first point—namely, that of the arrangement of shrubs, Mr. Loudon says that "there is one essential difference between the landscape gardener and the landscape artist which should never be lost sight of by the former, and this is that the materials with which he works are always changing, while those of the artist are fixed." Now this is especially the case in planting, as the trees introduced by the landscape gardener vary in height and form year by year, and in colour every season, so that he must know and take into consideration all these changes when he is planting, and even with all due thought and consideration there is yet a degree of uncertainty in Nature's growth. A tree, you will allow, is itself the noblest object of inanimate nature, and trees or shrubs, whether in masses or singly, produce, or help to produce nearly all the grand effects. What care, skill, and knowledge of the habits and in the planting of trees is then required by those who seek to produce a like result in garden scenery; and more than that, by those who seek to prune Nature of some of its roughness, and with the aid of art to add a more polished scenery to the foreground of the picture. Further on I hope to again say a few words in different places on planting.

I now come to the second important feature, that of undulation. The greatest charm of undulation lies in its softness and freedom; the lines should melt away into each other. Angularity, sharpness, or straightness are entirely out of place; correctness of eye, a nice judgment, and considerable taste are therefore required to produce a pleasing and finished result. Undulation, if delicately and cleverly applied, takes away that appearance of stiffness, and want of character and variety, which are often discernible in grounds that have been laid out by unskilled hands. With regard to my third point, that of finish, I refer to the clever and judicious distribution of the various parts of a design, the gradual transition from one point to another without any apparent interruption, the unobtrusive and almost imperceptible blending of one style with another, the perfect levels, the graceful curves of walks where curved, the accurate lines where straight.

I will now divide my paper into three parts, and say a few words

with reference—firstly to the general styles and principles of landscape gardening; secondly, to a few special subjects, embracing flower gardens, Rose gardens, kitchen gardens, water and lakes, rockeries, parks, and lodges; and thirdly, I will give a cursory sketch of the outline of work in laying out a place, and offer a few suggestions as to the practical treatment of walks, drainage, and planting.

There are three principal kinds of style recognised in landscape gardening. 1. The old formal or geometrical style where a garden is treated entirely as a work of art—*e.g.*, the Dutch garden. 2. The mixed, irregular, or gardenesque style, where more agreement with Nature is courted, through the aid of Art is still sought and valued. 3. The picturesque style, the distinctive characteristic of which is extreme naturalness.

The old formal or geometrical style is that which an architect would doubtless prefer, as it subordinates everything to the house, and is an attempt to carry out the principles common to both itself and architecture. Although this style has often been condemned as unnatural and absurd, it should not be looked upon as an attempt to imitate Nature, as a famous writer on the subject has well said, but as a display of the power of Art over Nature, and should therefore be judged like every other work of man by the end in view. It is a style admirably fitted to distinguish the garden scenery of the man of wealth from that of the common fortuitous scenery of the country around, and is utilised for that object. The geometrical style, however, has many inherent beauties of its own, as for instance that of a broad avenue. Who is there with any taste for the beautiful who has not been struck by the beauty and dignity of some of our old English avenues? The distinctive features of the geometrical style of landscape gardening are straight walks or walks branching off at right angles, beds formed in circles, segments of circles, ovals, oblongs, angles, or parallelograms, flights of steps, balustraded walls, terrace banks, raised platforms, sunken panels, exotic forms of vegetation, symmetry, correspondence of parts and gaiety of tone. The forms of Nature which are the most suitable for this style are those which are the most artificial in appearance, if it may be so expressed, as for instance round-headed standards, upright or fastigate shrubs, *Araucaria imbricata*, Irish Yews, Junipers (species of), *Arbor Vitæ*, Cypress, Cedar of Lebanon, species of *Cytisus* treated as standards, and many others. Purely town gardens can be treated in this style with great effect—that is, with terrace walks, flights of steps, sunken panels, vases filled with flowers and shrubs; but as a rule this style is only suitable for large gardens where the house or mansion is of the Grecian, Roman, or Italian style of architecture. It also is a most costly style, as it requires lawns to be the most perfect levels, grass, beds, and masses to be in the highest state of preservation.

The mixed or gardenesque style, as it has been termed, has as one of its most characteristic features curved or serpentine lines. Smoothness and freedom from angles are among its numerous indications, while the beauty and gracefulness of its lines are its chief object. This, however, does not entirely forbid the use of straight lines, but they must be in connection with the house or some subordinate building, such as a greenhouse or conservatory. It blends and interfuses Art with Nature, prunes Nature of its roughness by means of Art, drawing from each their most appropriate and agreeable elements, the grace of Nature without its ruggedness, the refinement of Art without its stiffness.

The last style in landscape gardening is that which has been named and worthily so too, the picturesque, a style which recognises no kind of symmetry or order, treating, as it does with broken ground, curious and bold forms of vegetation, rushing water, old ruins stained by time and age, and which yet possesses an indescribable wild grace so captivating to the eye.

The mixed style, with a little help from the geometrical and picturesque, is that which is best suited for small gardens, but care should be taken that one style only predominates, the other styles being quietly blended and introduced as subordinate features.

To turn to the general principles, simplicity demands first consideration. A design can be essentially simple without being crude and bald; intricate without being mazy. As simplicity is an element of true beauty, so also is it of the highest taste. A garden should be more or less simple in its arrangements according to its size and position, the lines all graceful, the decorations elegant. Intricacy brings into play a something beyond, a something more to explore, a newness of scenery, brought about by the clever grouping of plants, whether in masses or specimens, thus giving a charming variety of aspect.

Convenience is another principle which should be carefully studied. However tastefully a garden may be laid out it loses all its charm if comfort and convenience have not been provided for. Compact com-

position of the various parts, seclusion, an agreeable transition from one part of the garden to another without any decided break to disturb the harmony of the design are further principles which are always borne in mind by the successful landscape gardener. There is, however, one principle which must always be remembered by designers of a garden, and that is adaptation, for without adaptation no rules, no principles that can be given, will be of any real value. Every plot of land, whether it be half an acre or whether it be a hundred acres, has its own peculiar characteristics which should influence the disposal of its various parts, and give colour and variety to the whole design. It is, in fact, the delicate adaptation of the various rules, styles, and principles of treatment to the peculiarities and existing objects of each place, that brings credit to the landscape gardener and satisfaction to the owner.

(To be continued.)

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY

(Continued from page 203.)

Comtesse Panisse (Nabonnand, 1877).—Of fair growth, with fine foliage; not liable to mildew, and does tolerably as a dwarf; a full Rose, which therefore will not stand any rain and requires a hot bright sun. The petals are stout and good, and I had a fine bloom off my first plant, but have never had so good a one since. Not above the average size, and very changeable in colour. I see it is described in one catalogue as "rosy buff shaded with carmine and violet," which certainly seems sufficiently comprehensive, but amateurs will find that a great many of these Tea Roses come practically white; and the reason of this is, I suppose, that they are described as first seen under glass, but that out of doors they only open properly in bright hot weather, and then the sun "takes the colour out."

Comtesse Riza du Parc (Schwartz, 1876).—Of strong hearty growth, with good foliage, not liable to mildew or much injured by rain, late in blooming, not a good autumnal, and preferring a standard stock. This Rose "comes" very badly indeed, and a good shaped one is a decided rarity. It is not large nor a free bloomer, and has only survived from its colour, which is a charming shade of pink, with an indefinable sensation of yellow pervading it, especially at the base of the petals. It is already dropping out of the catalogue, but a good Rose of its colour would be heartily welcomed.

Devoniensis (Foster, 1838).—Of moderate but sturdy growth, nearly as thorny as *Comtesse de Nadaillac*, with small foliage; not very liable to mildew, nor (as becomes a native of Devon) as impatient of rain as some Teas. The strong blooms often come divided, but it is pretty good in petal, shape, centre, and size, though very liable to injury from frost. For a long time this was the best English-raised Tea Rose, and till lately it was highly rated, but now seems to me to be deteriorating. At all events, one does not see it shown so often as formerly, and I can do no good with it, as it appears to object strongly to being grown as a dwarf. Two catalogues at least describe this Rose as "pale yellow." I cannot tell why compilers fight so shy of the word "white," but they always seem to me to avoid it if they can.

Climbing Devoniensis (Pavitt, 1858).—I have not noticed the climbing sports of the H.P.'s, as they seem to me to be of little practical value, since the blooms are generally inferior to the type, and better pillar and wall Roses are to be found among the Noisettes, Gloire de Dijons, Ayrshire, Evergreen, or Banksias. Some nine or ten are catalogued, and oddly enough they are mostly sports of varieties which have quite a short growth naturally. This Tea Rose, however, "out-herods Herod" in differing from the *Devoniensis* type, which (as we have seen) is of quite moderate growth, but the climbing variety is the strongest, most untidy, and irregular grower we have. Growing is its strong point, and it sometimes nearly omits the flowering part of the business altogether. A strong long shoot of the *Gloire de Dijon* or *Noisette* races, if laid in well and uninjured by frost, will bloom freely all up the rod. But not so *Climbing Devoniensis*. Away it goes again (if well treated on a south wall) from the top bud of last year's shoot, and its sole endeavour seems to be to get to the top of the wall as quickly as possible, and as a plant to look as bare at the base, ugly, and lopsided as it can. The great pithy, thorny, flowerless shoots are very susceptible to frost, and are not handsome at any time. But I have seen it show better manners, growing moderately and blooming freely throughout the summer on a south wall, where no attention was paid to it; and I believe this desirable state of affairs was attained by simple starvation, but the buds were small and only useful as passab'e buttonholes.

Ernest Metz (Guillot, 1888) and *Ethel Brownlow* (Dickson, 1887) will, I hope, prove desirable members of our family, and set a good example in manners in general behaviour; but they are too juvenile as yet to have their characters described.

Etoile de Lyon (Guillot, 1881) is thus described in a catalogue of this season:—"This, without question, is one of the finest Tea Roses ever raised, and one which it will be difficult to supersede. It is a gem in every sense of the word, producing freely large and well formed flowers." Amateurs in general will probably not endorse this. The description, which is exaggerated under any circumstances, was no doubt taken from the Rose as seen under glass. This is necessary in the case of new Roses, but we look for more accurate characters of Roses eight years old. It seems to me a very disappointing Rose out of doors. It does well as a dwarf, and has good stout growth and foliage, rather liable to mildew, but the blooms come generally badly, of confused and queer shapes, and require as a rule very dry warm weather; yet did better, oddly enough, in the cold wet summer of 1888 than many others. It is what I call a disappointing Rose all round; for, when you do get a well shaped and regular bloom from a strong and very stout shoot, it is surprising how small and insignificant it looks when set up beside other Tea Roses cut from much slenderer and weaker stems. This is partly accounted for, no doubt, by the thoroughly globular shape, and by the outer petals being short, and kept close up to the rest of the bloom. Those are always the most effective shapes where the outer petals are the longest, and stand well away from the flower like great wings. It is something of the shape and colour of *Monsieur Furtado*, though larger, as indeed it ought to be, considering the great difference in growth. These two, *Etoile de Lyon* and *Monsieur Furtado*, with *Madame Bravy* and *Marie Guillot*, always seem to me the true types, if not the only perfect specimens, of the globular shape in Roses.

Francoise Kruger (Nabonnand, 1879).—A Rose which found little favour at first, but now yearly improves and increases in reputation. Of good growth and foliage, doing well as a dwarf, not much liable to mildew, and, when once it has commenced to expand, but little hindered by rain. It comes occasionally malformed or even with a green eye, but is often very perfect in form. A very free bloomer, and a good autumnal; the small buds are lovely in colour and shape, and a strong plant well thinned and attended to is capable of producing very fine exhibition blooms, large enough to show with H.P.s, and very lasting. A beautiful Rose, of very varied and changeable colour, strong large specimens when fully out, often showing an attractive and universal shade of yellow through all the inner petals.

Gloire de Dijon (Jacotot, 1853).—Perhaps the best known of all Roses. There can be little doubt that this is not a pure Tea, but has a cross in it of some other race, for the plant is absolutely hardy, of very vigorous climbing growth, and the foliage is unlike that of the Tea-scented China, and similar to that of *Grace Darling*. Like the *Noisettes*, Roses of this race must not have the strong young shoots pruned back, or wood instead of flowers will be produced; but, when this is understood, no Rose, save the common China or "Monthly," blooms so profusely and constantly, early and late, as the one under notice. Dean Hole says, "Were I condemned to have but one Rose for the rest of my life, I should ask, before leaving the dock, to be presented with a strong plant of *Gloire de Dijon*." Exhibitors are often blamed for neglecting Roses of real sterling merit like this one; but, though it has indeed many merits, it is not a show flower. A plant of *Gloire de Dijon* may be a hundred times the size of one of *Comtesse de Nadaillac*, and may have more than a hundred times the number of blooms; but take the finest *Gloire de Dijon* that ever was seen, and set it in a stand by a fair representative bloom of the other, and the great inferiority in every respect, even in size, would at once be manifest. The foliage is very fine indeed, but not so evergreen as *Maréchal Niel* and some other of the *Noisettes*, nor does it clothe the bases of the branches so well as *Rêve d'Or*. It is not liable to mildew, cares little for rain, and its bushels of blooms come very true to shape (which is weak to a florist's eye), and unusually uniform in colour. Last, but by no means least, among its good qualities, it will grow and flourish almost anywhere and anyhow, tolerably well even on a north wall. A Rose of such notoriety, which forms seed vessels freely, has naturally been a prolific parent of Roses of similar manners and customs, forming a race to themselves. Perhaps the best of these are *Bouquet d'Or* (Ducher, 1872), which, strange to say, is classed among the *Noisettes* in all the catalogues which I have seen except those of the N.R.S. and of Mr. G. Paul.—W. R. RAILLEM.

(To be continued.)

W. ALLEN RICHARDSON.

A LITTLE boy on being reproached with his bad manners and customs which were contrasted with the good ones of another little boy is reported to have said, "Perhaps so, but then he's been better brought up than I have." The "W. A. Richardson" described by Mr. W. R. Raillem in your last issue is never recognised by me or my family. If we meet him we do not see him, and this is not because we are proud, but because we are all so tall and such good climbers, although we don't approve of the custom which applies that term to Roses, that anyone less ambitious is known to have been badly brought up by those to whom he was entrusted in his early days, and to have acquired such low manners and customs as to preclude our acknowledging him. This is further shown by his producing a "very small" flower, and not all the care your correspondent and our friend may have lavished on him since he came to live with him will eradicate the faults thus early acquired.

We all certainly produce flowers sometimes nearly white, sometimes orange, and generally orange-ye low, edged with white, our true colour,

and we think this a good custom rather than a bad one, because variety is always charming, and we find people to love us in every state; but, as the dark Rose sometimes says when he puts on his chameleon change of brown—burnt, Mr. Raillem has the bad manners to call it—and gets hugely admired, "*Chacun à son goût*."—W. A. RICHARDSON.

MARÉCHAL NIEL CANKERING.

I AM very pleased to hear from Mr. Biron that canker in Maréchal Niel can be so easily cured. The usual place for it to occur is at the juncture of stock and scion, and the cause commonly assigned is that the former does not grow and swell fast enough to meet the demands of the latter. In such a case a cut through the canker down the bark of the stem, as used to the trunks of young Apple trees, seems a reasonable remedy, and it does appear strange that I should not have heard or seen it suggested before. My own Maréchal Niels have suffered little from canker, as they have generally been killed by frost before they have become old enough, but a large plant in my greenhouse has now been attacked, and, with many thanks to Mr. Biron, I shall certainly use his remedy, and hope it may be successful. Has he ever tried it on Apple trees actually cankered?—W. R. RAILLEM.

ROYAL HORTICULTURAL SOCIETY.

MARCH 11TH.

NUMEROUS exhibits of an exceptionally interesting character filled the greater part of the available space in the Drill Hall, James Street, on Monday last, and the visitors found a spring show of considerable beauty. Orchids were strongly represented; Hippeastrums formed a bright display, Daffodils were well shown, Camellias were uncommonly fine, Roses were included with miscellaneous spring flowers, and a valuable group from Kew added much to the attractions of the meeting.

In the afternoon Mr. H. J. Veitch discoursed upon Hippeastrums and their culture in a practical and popular manner, and a good number of Fellows and visitors assembled to listen to the lecture.

FRUIT COMMITTEE.—Present—Sir Charles W. Strickland, Bart. (in the chair), and Messrs. R. D. Blackmore, Harrison Weir, T. Francis Rivers, G. W. Cummins, J. T. Saltmarsh, W. Warren, J. Hudson, W. Denning, G. Wythes, F. Q. Lane, G. Bunyard, P. Veitch, J. Willard, W. Bates, G. Clyffe, H. Balderson, J. Cheal, Dr. Hogg, and J. Wright. This may be fairly regarded as the slack time of the year in the fruit world, and only a limited number of exhibits can be expected. The most notable contribution was a collection of Apples and stewing Pears from A. H. Smee, Esq. (Mr. G. W. Cummins, gardener), and for which a silver medal was recommended.

Mr. James Moore, Seymour Cottage, Swan Road, Sutton, Surrey, sent a dish of a seedling Pear from Bergamotte Crassane, medium-sized fruits of rich flavour, but much over-ripe. The Committee desired to see fruits in good condition another year, with information relative to the character of the tree. Mr. Miller sent a dish of Claygate Pearmain Apple from Ruxley Lodge, Esher. A dish of the same variety was also placed on the table from Smee's collection, this being the better of the two in quality, and votes of thanks were awarded. Messrs. R. Veitch and Sons, Exeter, sent a dish of Ashford's Seedling Apple, a favourite Devonshire market variety, raised by Mr. Reynolds of Ashford, Pinhoe, medium-sized, firm, fairly well-coloured fruits, used for dessert and culinary purposes. Some of the specimens were referred to Chiswick for testing their keeping properties.

Splendid dishes of stewing Pears grown by Mr. Cummins for Mr. Smee were placed on the table, the varieties including Catillac, Uvedale's St. Germain, Pius IX., Verulam, Winter Franc Real, and Besi Mai. A cultural commendation was unanimously awarded. Mr. Cecil Hooper sent a variety of small baskets for packing fruit, and a vote of thanks was accorded. Mr. Mil'ner, Ruxley, sent a bushel basketful of very fine Mushrooms, and a cultural commendation was awarded.

Mr. Smee's fruit, for which the silver medal was recommended, comprised about thirty varieties of admirably grown and well kept Apples, including a dish of the Gooseberry Apple grown in 1888, and the Pears above referred to. The recommendation of the medal was unanimous.

FLORAL COMMITTEE.—President, W. Marshall, Esq., in the chair, and Messrs. R. Dean, B. Wynne, W. Holmes, T. Baines, C. Jefferies, C. T. Druery, H. B. May, G. Nicholson, H. Herbst, James Walker, H. Cannell, E. Mawley, T. W. Girdlestone, C. Noble, J. Fraser, G. Paul, Harry Turner, and the Rev. H. H. D'Ombrian.

The group contributed from the Royal Gardens, Kew, comprised a number of rare and interesting plants, and the attention they attracted proves how much such collections add to the importance of meetings. Several members of the Aroid family were included, amongst them being *Godwinia gigas* with an enormous deep purple spathe, and *Arisema speciosum*, one of the smaller Aroids, of an ornamental appearance, the deep purplish brown spathes being regularly streaked with white, and the trifoliate leaves also give a bold appearance to the plant. Very remarkable was *Tacca artotharpifolia*, with flower stems 5 or 6 feet high, and bearing a cluster of flowers and long drooping filaments like the better known *Attaccia cristata*. Another curiosity was *Strelitzia Nicolai*, which has flowers similar in shape to *S. Reginae*, but the colours are white and purple, and it is consequently less showy. The Poison Bulb (*Buphane toxicaria*) was represented by a plant in flower—a dense

umbel-like head of dull crimson flowers, in the style of a *Hoemanthus*. It is from this bulb that the bushmen of South Africa are said to prepare a poison for use on their arrows. *Æchmea glomerata* may almost be counted amongst the curiosities, though it is also decidedly ornamental, the closely set bracts being scarlet tipped with purple. Rhizomes of the Arrowroot (*Maranta arundinacea*) were exhibited, and excited some interest in those who, though familiar with the preparation sold as arrowroot, had never seen the plant from which it is obtained. Of strictly ornamental plants several *Rhododendrons* were the most notable. *R. arboreum* and the variety *roseum*, together with *R. grande* (*argenteum*) were represented by fine heads of flowers; *Brownea arhiza* has somewhat similar dense trusses of flowers; *Acacias retinoides* and *verticillata*, with yellow flowers, are useful species, the former very fragrant.

From Messrs. J. Veitch & Sons came an excellent historical group of *Hippeastrums* (*Amaryllises*) representing the gradual advance effected since the old *Acramani pulchella* was sent out. This variety, with *Crocea grandiflora*, *Johnsoni*, *Graveana*, and others of the early improvements were shown, and there were also plants of *reticulata Leopoldi*, King of the Crimson, *Empress of India*, and a grand new variety named *Champion* (certificated). In another group were plants of *Azalea mollis* varieties, *Andromeda japonica*, *Boronias megastigma* and *heterophylla*, and *Primula obconica*.

Camellias are annually expected about this time of year from Messrs. W. Paul & Son, Waltham Cross, and at this meeting the yearly contribution comprised twelve large boxes of handsome blooms, for which the Committee awarded a silver Banksian medal as a recognition of their merits. Numerous varieties were represented, most of the best old and new varieties being included.

Daffodils and hardy flowers furnished a beautifully bright and fresh group as staged by Messrs. Barr & Son (bronze medal). Double and single *Narcissi* of many varieties were there with the brilliant *Anemone fulgens*, *Chionodoxas*, *Crocuses*, *Iris reticulata*, and *Snowdrops*. A group of foliage plants and Ferns from Mr. H. B. May (silver medal); and Messrs. Paul & Son, besides the *Coelogyne* already noted, had some boxes of fresh and beautiful Rose blooms and a pyramidal plant of *Rosa polyantha grandiflora*. Mr. H. Porter, Freshfield, Liverpool, sent a plant of an *Adiantum* named *Porteri*, said to be the result of a cross between *A. cuneatum* and *A. gracillimum*, but it seemed to be a variety of the former with slightly smaller pinnules. Messrs. H. Cannell & Sons, Swanley, were adjudged an award of merit for a collection of well grown *Cinerarias* bearing richly and diversely coloured flowers. Mr. J. T. Gilbert, Dyke, Bourne, Lincolnshire, showed some Crown Imperials and a large flowered Primrose named *Primrose Dame*. From the Society's garden also came plants of the peculiar *Billbergia nutans* with green flowers edged with purple and pink bracts.

ORCHID COMMITTEE.—Present: Harry J. Veitch, Esq., in the chair; and Messrs. F. G. Tautz, F. A. Philbrick, Lewis Castle, Henry Williams, E. Hill, J. Douglas, J. Domyne, H. Ballantine, H. M. Pollett, F. Sander, James O'Brien, and Dr. M. T. Masters.

From Messrs. Sander & Co., St. Albans, came a handsome group of choice Orchids, for which a silver Banksian medal was recommended, and several certificates were also adjudged for novelties included in the group. Very notable were well grown plants of the beautiful *Phaius tuberculatus* on rafts or in baskets, and bearing fine spikes of its remarkable flowers. At St. Albans this Orchid is grown in a warm house, suspended above a tank, and flourishes there in a surprising manner. *Dendrobium litiiflorum superbum* is a fine variety, with large flowers and deeply coloured. A curiosity was noticeable in *Oncidium heteranthum*, having two forms of flowers, one with the ordinary rounded sepals and petals, yellow, and brown, and white; the other small, with linear creamy white segments. Several large specimen plants of *Dendrobium nobile* varieties were shown, and a large *D. Wardianum*; a new species of *Lycaste* in the way of *L. aromatica*, but distinct and wanting its fragrance; *Oncidium cruciatum*, *Selenipedium Sedeni virginale*, several *Maxillarias*, and the certificated plants described at the end of this report.

Messrs. B. S. Williams & Son, Upper Holloway, also contributed a beautiful group of Orchids most tastefully arranged with Palms, Ferns, and other foliage plants. The *Odontoglossums* were especially noteworthy, several varieties of *O. crispum* being remarkable for the size and excellent shape of the flowers. *O. cirrhosum* was well represented, as were also *O. Andersonium*, *O. odoratum*, and *O. facetum*. There were capital examples of the fragrant and graceful *Dendrochilum glumaecum*, the peculiar *Phaius maculatus*, and the greenish flowered *Dendrobium macrophyllum*, with several plants of the pure white *Coelogyne cristata alba*. Amongst other plants the fragrant *Boronia megastigma* was admired, the neat salmon coloured *Azalea rosæflora*, and the double form of *Sparmannia africana*.

Messrs. J. Veitch & Sons, Chelsea, exhibited a small group of valuable and beautiful hybrid Orchids from their extensive stores, and in addition to these, certificated and described, the following were noticeable:—*Cymbidium eburneo-Lowianum*, with buff coloured flowers, attracted attention, but it has been previously certificated; *D. Wardiano-japonicum*, from a cross between the two species expressed in the name, was considered to be in the way of *D. transparens*, and the effect of *D. Wardianum* was not very evident; *D. micans*, from *D. Wardianum* and *D. litiiflorum*, partakes of the colouring distinguishing the last named, and is a decidedly pretty Orchid; *Cypripedium Othello*, from *C. hirsutissimum* and *C. villosum* Boxalli, is an interesting cross, but not sufficiently developed at present to merit an award. Messrs. J.

Laing & Sons, Forest Hill, sent several excellent varieties of *Cattleya Trianae*, for one of which an award of merit was granted; also the bright red *Carnation Madame Arthur Warocqué*, one of the *Souvenir de la Malmaison* type. Messrs. Paul and Son, Cheshunt, exhibited plants of *Cœlogyne cristata* and its varieties, for which an award of merit was adjudged.

Amateurs' exhibits were numerous and good. Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, sent the yellow flowered *Dendrobium signatum*, which was certificated, and *Dendrobium Smilliae*, a peculiar and interesting species, with short racemes terminating in the stout pseudo-bulbs, the flowers small, pink and white, with a knob-like deep green lip. G. Appleyard, Esq., Savile House, Savile Road, sent a charming spotted *Odontoglossum* bearing the name of Appleyardianum, somewhat resembling *O. hebraicum*. Mr. G. Wythes, Syon House Gardens, Brentford, showed flowers of *Cœlogyne cristata* and *Cypripedium villosum*.

H. Mark, Esq., Cheriton, Albemarle Road, Beckenham, Kent, exhibited a plant of *Oncidium tetracopis*, with brown sepals and petals, the lip being marked with yellow and brown. F. G. Tautz, Esq., Studley House, Hammersmith (gardener, Mr. Cowley), showed a dark coloured variety of *Cypripedium selligerum*, named *rubrum*, the whole of the flowers of an exceptionally rich tint. A plant was also shown under the name of *Cypripedium Rothschildianum*, which was determined, on reference to the Committee, to be *C. Elliottianum*, and an opinion was expressed that the figure published in the "Botanical Magazine" under the name of *C. Rothschildianum* really represents *C. Elliottianum*. A very distinct variety of *Odontoglossum Pescatorei* came from the same garden, and was certificated.

PLANTS CERTIFICATED.

Dendrobium Aspasia (J. Veitch & Sons).—The result of a cross between *D. Wardianum* and *D. aureum*, and two plants were shown in which, while the flowers were practically identical, the habit of growth was very different, the strong and tall one resembling *D. Wardianum*, the other much shorter and like *D. aureum*. The sepals and petals are light-coloured or nearly white, tipped with purple, the lip somewhat like that of *D. aureum*, with a central golden bronze blotch, margined with white and tipped with purple. A handsome and distinct hybrid; a decidedly valuable addition to those already raised by the same firm.

Cypripedium Numa (J. Veitch & Sons).—A hybrid obtained from a cross between *C. Stonei* and *C. Laurencianum*, and resembling one that has been already named *C. Godseffianum*. The flowers are dark coloured, the dorsal sepal heavily streaked with maroon, the petals spotted with a similar colour, the lip like *C. Stonei* in shape but much darker in hue.

Lycaete Skinneri, *Young's Variety* (F. Sander & Co.).—A magnificent variety with white sepals, the petals and lip tinged with a peculiarly delicate and distinct shade of apricot, tinted pink. An excellent novelty.

Phaius hybridus Cooksoni (F. Sander & Co.).—A remarkable hybrid raised from a cross between *P. tuberculosus* and *P. Wallichii*, the latter being the seed parent, and it was obtained by Mr. Norman Cookson at Wylam-on-Tyne amongst the many treasures which he has secured. *P. Wallichii* is a tall strong growing species with large brownish flowers and white sepals, and *P. tuberculosus* is one of the most delicately beautiful Orchids in cultivation, the markings and colouring of the lip being almost indescribable. The hybrid is somewhat stronger in growth than the pollen parent, but much less so than the seed parent, while in the flowers it presents a strange combination of the colours. The result is that the lip is a peculiar purplish bronze, the sepals and petals tinted with pink and a brownish suffusion running through them. It is one of the hybrids in which the fusion of characters can be seen at a glance.

Cypripedium Schomburkianum (F. Sander & Co.).—An interesting new species of the *Selenipedium* section, from the Roraima, with neat flowers, the lip yellowish green, the petals long, narrow, and drooping (botanical certificate).

Phoenix Ræbelini (F. Sander & Co. and James O'Brien).—A dwarf Palm, with dark shining green pinnate leaves 9 to 12 inches long and 6 to 8 inches broad, the pinnæ narrow and straight. It is compact in habit, graceful, and is said to be of exceedingly slow growth, consequently it is well adapted for decorative purposes where small plants are required.

Cattleya Trianae marginata (J. Laing & Sons).—A beautiful variety, in which the lip has a clearly defined white margin, contrasting with the richly coloured central portion. The flower is of good shape, and the petals broad (award of merit).

Camellia La Vestale (C. Turner).—It is seldom that additions to the certificated Camellias have to be recorded, but that named above is a charming novelty. The flowers are pure white, of excellent symmetrical shape, the outer petals slightly recurving, and it is therefore not quite so flat as the well-known variety *alba*.

Odontoglossum Pescatorei melanocentrum (F. G. Tautz, Esq.).—Very distinct and effective, the sepals and petals pure white, the base of the lip and column being a deep crimson, which shows up on the white ground colour, and from that the name is derived.

Oncidium Larkianum (J. Larkin, Esq., Derriville).—A supposed hybrid between *O. Gardnerianum* and *O. Marshallianum*; the lip bright yellow, large; the sepals and petals brown, edged with yellow (award of merit).

Angraecum hybrid (H. Low & Co.).—An interesting little Orchid, apparently a hybrid between *A. hyaloides* and *A. citratum*, and strangely intermediate in both floral and habit characters between the species named.

Dendrobium signatum (Sir Trevor Lawrence, Bart., M.P.).—A yellow flowered species, suggestive of *D. luteolum* in the shape of the flowers, the sepals and petals recurving, and the lip having a dark blotch in the centre.

Hippeastrum (Amaryllis) Champion (J. Veitch & Sons).—A grand variety with finely proportioned flowers 9 inches in diameter, the perianth divisions nearly 4 inches across, and of a rich deep scarlet colour.

Cattleya Trianae fulgens (H. B. Mildmay, Esq.).—Very handsome, the petals extremely broad, of a purplish mauve tint, the lip intense crimson and gold in the throat (award of merit).

FRUIT FORCING.

VINES.—*Early Forced Vines in Pots.*—These must sustain no check through dryness at the roots, affording tepid manure liberally, surfacing the soil with rich material, and if the roots extend beyond the pots feed them there as well. Secure a good moisture by damping in the morning and early afternoon, also before nightfall, maintaining a night temperature of 65°, 70° to 75° by day, and 80° to 85° with sun heat, and close early to keep it to 85° or 90°. When the Grapes begin colouring still continue the atmospheric moisture, and feed liberally, as the fruit swells considerably after commencing to colour, and to enhance the quality maintain the temperature named with sufficient ventilation constantly to insure a circulation of air.

Early Forced Planted-out Vines.—In houses started early in December the fruit is thinned and swelling freely. The border, especially in the vicinity of the hot-water pipes, must be duly supplied with water somewhat in advance of the temperature of the house, liquid manure materially assisting in swelling the berries. Mulch the border with short but rather fresh manure, or a few fresh droppings sprinkled on the surface occasionally will afford much benefit to the foliage and roots, but they must not be given too liberally or the ammonia arising will injure the foliage. Maintain a genial condition of the atmosphere by damping in the morning and at closing time or early in the afternoon. Ventilate early, but not before 70° to 75° is reached, securing with increased ventilation and sun heat a temperature of 80° to 85°, closing early to husband the sun heat. At night 60° to 65° is suitable, and 70° to 75° by day artificially.

Houses Started in January.—The Vines are in flower or advanced to the thinning stage. Secure a night temperature of 65° to 70°, 5° more for Muscats, 70° to 75° by day artificially, and 80° to 85° with sun heat. Maintain a moderately dry atmosphere, ventilating constantly. Fertilise all shy-setting varieties carefully. Early Vines do not make the progress desired, especially those with the roots in cold borders unprotected sufficiently from cold rains, snow, and frost. The Vines break badly, and the bunches show a tendency to blindness, some of them running to tendrils and others not advancing freely. Under such circumstances a slight increase of temperature and a reduced supply of moisture for a short time may be beneficial. Bright sunny days with sharp winds render careful ventilation necessary. Avoid sudden changes of temperature, and admit air in small quantities at a time, avoiding cold currents.

Houses Started Early in February.—Breaking into growth freely, these require attention in disbudding and regulating, stopping them two to four joints beyond the bunches according to the space. Stop the laterals up to the fruit at one joint, or remove them altogether except from the two lowest leaves; those above the bunches may be allowed to make two or more joints before being pinched, but no more foliage should be encouraged than can have full exposure to light. Remove all superfluous bunches, also ill-shaped bunches of the free-setting varieties as soon as those that are the most promising for the crop can be determined. Raise the temperature to 60° at night, 65° by day from fire heat, and up to 75° to 80° with sun heat.

Houses to Afford Fruit in August and September.—Start the Vines at once, making the inside borders thoroughly moist by the application of liquid manure or water at a temperature of 80°. It will in some degree stimulate the roots and compensate for the inactivity of those in the outside borders, which do not as a rule become active until a mean of 50° is assured, and which does not take place ordinarily until early April. Fermenting materials, however, can do little good after this. The atmosphere should be kept moist by damping the rods and every available surface two or three times a day, 50° being a sufficiently high night temperature, and 65° by day with sun.

Late Houses.—The necessity of starting late Grapes in good time is evidenced by the numerous instances of indifferent ripening and keeping

that are seen in autumn and spring, a longer period of growth being mostly all that is needed to produce good sized and highly finished fruit, and such as possess good keeping qualities. Syringe the rods several times a day, maintaining a moist atmosphere by damping the borders every evening. It is advantageous to cover the inside border with fresh stable manure, the straw being shaken out, the ammonia given off having an invigorating tendency. Night temperature 50° to 55°, day 55° to 60°, and 10° to 15° more with sun, and rather free ventilation from 65°.

Young Vines from Eyes.—Those struck and potted as advised in our last calendar are now well rooted, and should be shifted as soon as the roots reach the sides of the pots into 6-inch size, placing them on shelves over the hot-water pipes in preference to plunging them in bottom heat. Syringe amongst them, and pinch the laterals at the first leaf, unless they are intended for planting out this season, when the laterals may be left intact.

Cut-back Vines in Pots.—Those for fruiting in pots next season will soon be fit for turning out and shaking out of the soil, and any long bare shoots cut back and placed in 7 or 8-inch pots, from which they can be transferred when established to 12 or 13-inch pots. If these, or the eyes named in the preceding paragraph have been plunged in bottom heat, they may be returned to it for a time, 75° to 80° being suitable, but otherwise bottom heat is not necessary. Keep them close and moderately moist until they are established. Train the canes near the glass, as they cannot have too much light, it being important that the growth be solidified as made. Turfy loam rather rough, with a fifteenth of steamed bone meal added, form a suitable compost for Vines in pots. Clean pots and efficient drainage of clean walks must be employed in pot Vine culture.

MELONS.—The weather being cold but with bright days, the advance has been satisfactory. Plants that were shifted into larger pots and being intended for planting out, should be given their fruiting quarters before they become very much root-bound. Pot later sown plants when they show the second leaves, employing warm moist soil.

Melons in Dung-heated Frames.—The plants from the seed sown early in February will be fit to plant out. Make up a bed for them, and make also a successional sowing. Those growing Melons in frames and having to keep up a successional supply of fruit should make a sowing every fortnight or three weeks up to May, making fresh beds at similar intervals to receive the plants, so as to maintain an uninterrupted supply of fruit. Maintain a night temperature of 60° to 65°, and 70° to 75° by day, as far as practicable, by timely attention to the linings and coverings over the lights at night, admitting air from 75°, but without lowering the temperature, and keep through the day at 80° to 85° from sun heat.

In houses and hot-water heated pits maintain a night temperature of 65° to 70°, 5° less on cold nights, 70° to 75° by day, admitting a little air at 75°, allowing the temperature to rise to 85° with increased ventilation, closing at 80° or 85°, sprinkling at the time every available surface; and if the temperature rise to 85° or 90° so much the better. Keep the bottom heat at from 75° to 80°.

CUCUMBERS.—Increased light and sun heat correspondingly increase evaporation, necessitating a greater supply of atmospheric moisture. Damp the house so as to maintain a genial condition of the atmosphere, and syringe the plants lightly during bright afternoons. A night temperature of 65° is sufficient, allowing 5° advance when the external air is mild, 60° being the minimum in the morning when the external air is cold. Liquid manure may be given once or twice a week, and the evaporation troughs kept charged with it. Do not allow the fruit to hang too long, or they may weaken the plants; besides, they keep fresh for several days with their stalks inserted in saucers of water. Thin the fruits well, especially on plants just coming into bearing, stopping the shoots one joint beyond the fruit, removing superfluous growths and bad leaves as they appear, as well as staminate blossoms.

The weather continuing unfavourable for early forcing in pits and frames heated with fermenting material, the temperature being difficult to maintain at a point calculated to promote steady progressive growth, a close atmosphere resulting in a superabundance of moisture, not unfrequently causing the loss of the plants. When the moisture cannot be expelled, much may be done by sprinkling dry lime or soot round the plants, those substances having a strong affinity for moisture. Continue to prepare material for making fresh beds and lining purposes, and sow seed as successional plants are required.

FIGS.—*Planted-out Trees Started Early in the Year.*—Attention must be given to the budding and stopping, removing all the overcrowded shoots, stopping those intended to form well developed spurs for the second crop at the fifth or sixth leaf or joint, the leading shoot, where there is space, being allowed to extend, as they invariably afford the finest fruit. Water the borders freely with liquid manure at 80°, taking care not to apply it too strong, and mulch with rich compost, which will attract the roots to the surface. Encourage also the emission of roots from the stem by placing fibrous pieces of turf and partially decayed manure in contact with it, and by extending the material outwards a quantity of feeders will be secured, which if supplied with warm liquid manure will greatly assist the maturity of the fruit.

STRAWBERRIES IN POTS.—Vicomtesse Hericart de Thury is perhaps the best flavoured and prettiest fruit for jellies, but it makes no appearance beside Noble or La Grosse Sucrée, one of either weighing three of the first-named. All plants should now be in position for advancement by gentle forcing, or if not they should be brought under glass

without further delay. Some may be advanced by placing them in houses where there is a gentle heat, and others may be placed in cool houses where they will come on gradually. In all cases it is necessary to examine the drainage, removing any moss or other matter from the surface of the soil, and wash the pots, surfacing with horse droppings rubbed through a sieve, which prevents the soil leaving the sides of the pots and discourages action at the surface. Until the trusses are showing it is well if the temperature does not exceed 50° by artificial means, and between that and setting 55° is safe, advancing to 65° by day with free ventilation. The Strawberry also likes plenty of light until the fruits are set, but afterwards they are apt to become dried, hence they swell best in positions where the sun's rays are not strong at mid-day. After the fruit is set and swelling a temperature of 60° to 65° at night, 70° to 75° by day, with an advance from sun heat to 80°, 85°, or 90° is necessary, affording copious supplies of water and liquid manure until the fruit shows indications of ripening, when somewhat drier and more airy atmosphere with diminished supplies of water at the roots will afford large, well-swelled fruit of good flavour. Thinning the fruit must be attended to as soon as the setting is completed, removing the smallest and deformed fruit; and on no account must there be insufficient water at the roots during the swelling, but during flowering the soil must be kept moist, avoiding extremes either way. The chief object in Strawberry forcing is to secure an early and unbroken supply until those in the open ground come in, and this, where there is a number of houses started at intervals, will admit of its being done without much trouble or change of plants, whilst in others some tact will be necessary to meet the requirements.

KITCHEN GARDEN.

THE WEATHER.—March came in with snow and frost, 18° of the latter being registered with us on the 3rd. Many seeds were sown in the open ground, but of these we have little fear. As soon as the weather changes kitchen garden work will be resumed, as we like to have it well advanced before the end of the month.

TURNIPS.—A few rows will be sown on the first opportunity. Two sowings are sufficient in March. The Early Milan is the best for a first crop. Sow in drills 1 foot apart on a sheltered piece of ground. A moderately light soil is better at first than heavy material.

MUSHROOMS.—More beds should still be formed, as they will bear in April or May when vegetables may be scarce. Beds in the open air and cool sheds may be relied on. Our beds of this winter have not required much attention, and they have been unusually productive. Those which began bearing in November are exhausted, and being used on some of the vegetable quarters, particularly for Carrots and Beetroot, where rank manure is objectionable. Others that have been bearing since the new year and now declining will have a thorough application of water heated to 90°. When slightly dry they will be retrenched and covered with hay. This will generate fresh heat, and we shall have a very good second crop of Mushrooms in April.

CABBAGES.—These promise to be ready by Easter. They have received a slight check, but being sturdy, will soon recover under mild weather. A sprinkling of nitrate of soda will expedite growth. Guano is the next best stimulant, and the plants will be benefited by having a little more soil drawn to their stems.

SEAKALE AND RHUBARB.—These may now be forced with little trouble. If a quantity of straw or littery stable manure is put over the Seakale crowns the growths will soon push up into it and turn out clean and well blanched. This is a good substitute for pots, but the latter may be used by those who possess them. Rhubarb now shows signs of growing without any forcing, but to hasten the supply a few old boxes or casks may be turned over the crowns with or without a little hot manure round them. We placed some Rhubarb roots on a hotbed in December. Others were covered over as suggested with a good hotbed, and the latter have been much the more profitable.

GARLIC AND SHALLOTS.—A supply of both should be provided. Select some of the best bulbs, fork a rather light piece of ground and press the bulbs into it at a distance of 10 inches from row to row, and 6 inches from bulb to bulb. We merely cover them with soil, and never fail to have abundance. The Shallots are harvested and housed in autumn, but the Garlic may be left in the ground year after year. It is never wanted in great quantities, but a little is often called for.

SOWING SEEDS IN HEAVY SOILS.—Many growers complain that they cannot sow their seeds early because their soil is so heavy and cold. This is undoubtedly a great drawback. One of the greatest aids to germination is the free use of potting shed refuse, or sand, leaf soil, and wood ashes. If the ground is very heavy and wet the drills for the seed should be opened twice the ordinary depth, half filled with the mixture for sowing in, and the seeds covered with more of it. By following this practice all kinds of vegetables may be sown early in strong soils.

PARSLEY.—If the first sowing has not been there should be no further delay. The seed and young plants are very hardy. Parsley likes rich ground. Old plants are now somewhat deficient in leaves. Some of the largest have perished, and should be removed. A quantity of soot or guano sprinkled between the plants, and the Dutch hoe run amongst them will induce quick growth, and the supply will be maintained till the spring sown plants furnish leaves.

HORN CARROTS.—It is useless sowing the long varieties for early crops; the Horn varieties only should be sown in March, and those who have not placed seed in the ground should do so as soon as possible.

BROAD BEANS.—The December sown Mazagans are up and healthy. Their produce will be very acceptable, but we like the Longpod type better for a second or main crop, and these may now be sown in rows 2½ feet apart in the strongest soil in the garden, and do not fail to give them plenty of manure if long succulent pods are desired.

EARLY CELERY.—The seed sown some weeks ago has produced plants that are now ready for pricking out. These may be inserted in shallow boxes, but the best way is to transplant them 2 inches or 3 inches apart in free soil on a firm, gentle, hotbed, and protect with glass; water immediately, shade from bright sunshine for a few days, keep them sturdy by judicious ventilation, never allow them to suffer by want of water, and serviceable plants will be the result.

BRUSSELS SPROUTS.—The present is a good time to sow in the open for the main crop. The plants will be more useful next winter than those sown under glass, and which will button in August. The seed may be sown broadcast thinly and covered to the depth of half an inch.

PLANT HOUSES.

Bertolonias.—Young plants that were raised from cuttings in autumn and have been well preserved through the winter, may now be placed in 4-inch pots. Bertolonias grow well in a compost of peat and sphagnum in equal proportions with the addition of sand, covering the surface with a thin layer of moss. In potting slightly raise the plants above the rim of the pots, so that a pair of good leaves rest on the surface of the compost. No harm will be done by the removal of a pair or two of small leaves at the base, as roots will be produced from the stem, and larger foliage will result. In the majority of ordinary stove structures it will be necessary to grow the plants under bell-glasses, handlights, or in a frame so that they can be kept close and moist. It is necessary to tilt the lights daily, if only for a short time, to prevent the atmosphere from becoming stagnant. The tops from old plants or any side shoots that are upon them may now be rooted. The cuttings may be inserted singly in small pots in the compost advised above. Place a good pinch of sand in the centre to surround each cutting. They will soon root in brisk bottom heat in the propagating frame if kept close and shaded from the sun.

Sonerilas.—To have pans and pots of these in good condition cuttings must be inserted at once. They root freely in the propagating frame in sandy soil or, better still, all sand. They may be inserted thickly together in pots or pans, and transplanted into others as soon as they are rooted. They do well in the compost advised for Bertolonias, and will flourish in any stove where the atmosphere is close and moist, if a shady position is found for them. They are effective growing amongst the moss in pots of Vandas, Acridas, and other Orchids of a similar nature.

Fittonias.—A few good pans of these are effective in the stove, and should find a place where the object is to maintain this structure attractive throughout the season. For this purpose insert cuttings at once. They root freely in any close, moist and shady position if placed amongst chopped sphagnum moss and sand. When well rooted plant them in the pans in which they are to grow. They are most effective when well elevated in the centre. They grow luxuriantly in the compost advised for Bertolonias. Where small plants for various forms of decoration are in demand few surpass these in beauty when mixed with Mosses and small Ferns.

Panicum variegatum.—Cuttings should be rooted in quantity, for this Panicum is most effective in baskets suspended from the roof and for the margin of the stage. It grows so rapidly when once started and given favourable conditions, that in a few months it will furnish the whole space between the stage and floor of the house. The cuttings may be inserted in the pots in which they are to grow. The pots may be filled with equal parts of loam and leaf mould, with the addition of sand and one-seventh of manure. A good layer of sand should be placed on the surface. Those for baskets and other positions may be inserted in pans and transplanted when they are rooted. They root best in a close propagating frame.

Selaginella caesia.—Associates admirably with *Panicum variegatum*, and it would be impossible to produce a more pleasing effect than the two plants growing together alternately. The *Selaginella* may be in slightly the larger pots of the two, or before the close of the season it is low by the side of the other. They may be divided and started into growth, either in the stove or any structure, until they are sufficiently ornamental for placing in a permanent position. Equal parts of loam and leaf mould, with the addition of sand, form a suitable compost. Where Orchids are grown, and fine peat is plentiful, it may be used at the rate of one-third with the loam and leaf mould without the slightest risk of the plants not doing well.

Anthurium Andreanum.—Plants that have grown tall may be cut into lengths that have one good eye, and inserted singly in small pots in sphagnum moss and sand. The old foliage should remain on the pieces until they are rooted and commence growing, when they can be removed. Place a good pinch of sand at the base of each, and plunge the pots containing them in brisk heat. Portions of the stem root freely, and by autumn will make strong flowering plants. Throughout the autumn and winter the bright scarlet spathes are most effective. The old "stool" if not disturbed will soon make five or six shoots from the base, and in two years will develop into a fine large specimen. Propagate only from the best varieties. Anthuriums are handsome when secured to upright pillars used for the support of the roof.

THE BEE-KEEPER.

NOTES ON BEES.

THE weather since February 23rd has been cold and frosty. The mean temperature up till March 2nd was 27½° Fahr. The lowest temperature since winter commenced occurred on the morning of March 2nd, the thermometer indicating 22° frost, standing at 10°. So low a temperature after so much mildness has had a telling effect on nuclei or weak stocks of bees. I have been an eye-witness to many that tided over the winter well until that morning, when they succumbed. The dead bees in every case were located on the opposite side from the honey, but there is nothing new in that. What I wish to impress upon beginners is the condition in which hives should be wintered. It will be observed the bees did not die through want of food being in the hive, but through being in the wrong part of it. I have as weak hives living as those that are dead. They live because in the fall I packed the honeycombs all on one side, compelling the bees to cluster with the honey on one side. The bees in deep combs naturally leave passages, so that a freer communication from one comb to another is created for their own conveniences. The Americans tried to improve upon this, and drilled holes in a straight line, instead of the zigzag form of the bees, and many in this country imitated the American plan. Combs so drilled aggravate disaster to bees, as they create a direct draught, which lowers the atmosphere and so benumbs the bees that it is impossible for them to move about in search of food, especially when they have been advancing to the side with the least quantity of honey. Bees, although few in number, will not die if the honey is all on the one side; but it is better if it is overhead. I never knew a hive of bees to perish from want when the honey was above them, nor do I believe they ever will. It is the natural place for it, not only in winter but at all times, and the proper hive for that is the storifying one.

AUTUMN-GATHERED POLLEN.

I have stated often that I never had a hive that suffered from being pollen-bound, nor do I believe I ever shall. Modern bee-keepers have discovered that there is some fatality in having a good supply of pollen in the hives during winter, and advise removing it. When I see a plant under my management not growing as I wish I try to discover the cause, and then adopt the remedy. When bees show signs of something wrong I know that I have bungled, and arrange matters so that the bees can act according to their instinct as well as to my profit. To remove pollen-laden combs from a hive in autumn is a simple mode of frustrating the advance of bees at the most important season relative to the profit of bee-keepers. I question if the advocates for removing pollen from hives in autumn can give a satisfactory answer why they do so, or the advantages gained. Some of my hives that in autumn had an extra supply of pollen are far advanced, and if the weather is favourable are sure to be profitable. Had I removed the pollen in autumn the eggs that have matured into young bees would have been all destroyed.

FLOWERS FOR HONEY.

"I intend starting bee-keeping this summer, and should be glad to know what flowers and shrubs are most suitable for the production of honey. Any hints as to the best kind of hive for a beginner would also be appreciated.—W. J. S."

The above question covers by far too wide a range to be answered satisfactorily. If the extent of the ground had been stated a selection could have been better given. It is only where there is a good extent that honey producing flowers are profitable—i.e., where bees can gather surplus, and Clover is the first and best. Beans are good for honey, and where a demand for the seed

of Turnips or other of the Brassica tribe exists one sort might be grown. Fruit trees and bushes are all honey producing, and are more profitable, and in many cases as ornamental as some kinds of shrubs. Of the latter the Laurustinus, Willows (the male for pollen and the female for honey), Berberis, Lilac, Cotoneaster microphylla, and nearly every flowering shrub and tree are honey or pollen producing, and not unfrequently both. Amongst garden flowers are the Aconite, Snowdrop, Crocus, and Hellebore; Anemone cœrulea is a great favourite. Poppies for pollen and Mignonne for honey and pollen are good annuals, so are Godetias. Arabis is perhaps the best spring plant, but all the Cruciferae family are useful.

Some flowers appear to have a fragrance that tempts the bees to them, but no honey or pollen, or so little that the bees get no good from them, working for hours without showing signs of either pollen or honey. This seems the point where the line can be drawn between instinct and reason. The greatest advantage is in having spring and autumn flowers in profusion. The latter keep the bees out of danger when they would otherwise be disposed to rob or be entrapped in shops or houses, as well as to be storing a supply of pollen for spring breeding. The spring flowers, although not directly profitable, encourage the bees, resulting in strong hives at the proper time, which without bee-keeping in many cases would be a failure. It is a delusion to say that uncapping cells of honey and feeding in dribblets forwards the bees. It is the profusion of flowers, combined with the genial warmth of spring, that stimulates bees.

Apart from the usefulness of flowers for bees we have their pleasure at all times, and as many of them are sensitive to changes of weather and approaching rains we can often predict a storm a long time in advance. A bed of Poppies never deceives us, neither does the Chickweed, and Tulips will sometimes lounge before a gale bend their heads from its direction. If carefully watched our native plants will tell the coming weather as well as many of the tender exotics.

THE BEST HIVE.

The Lanarkshire storifying hive is without doubt the cheapest and most serviceable hive in use. Its principles, both at home and on the continent, are every day becoming more in repute. Full instructions for making will be found in previous issues of this Journal.—A LANARKSHIRE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Cool Orchids (Inquirer).—You will find full instructions respecting the culture of cool Orchids in Mr. B. S. Williams's "Orchid Growers' Manual," in Messrs. Veitch & Sons' "Manual of Orchidaceous Plants," part i., or in Castle's "Orchids: Their History and Culture," published at this office, post free 1s. 2½d.

Alternantheras (P.).—Thousands of these plants are grown in boxes in the manner you propose, and planted from them direct to the beds in June, or when the weather permits. They should have a tempera-

ture of not less than 60°. The variegated Mesembryanthemum may be treated in the same way, but the soil does not adhere to the roots so well. If you can dig some turves 2 inches thick or so, char the grass sides, cut into 2 inch squares, inserting a cutting or rooted plant in each, with sand falling in round it, and pack these squares closely in boxes, covering with leaf mould or light soil, the plants will be in excellent condition for transplanting in due time.

Grafting Pears (C. E.).—You may insert one scion in each branch, two if the branches are as thick as your wrist, and if both grow retain the best for the future branch, removing the other. As many branches as there are now, provided they are not much less than a foot apart, just so many you must provide for forming the future tree. The scions, well-ripened wood of last year, should be taken off at once and covered with soil or cocoa-nut fibre refuse on the north side of a wall to keep them fresh and retard their growth.

Packing Fruit (R. C. L., India).—American Apples are sent to this country in barrels, the fruit being firmly pressed down without any packing. Each barrel holds about three bushels. Much fruit is sent from Kent to London in round, very strongly made, bushel baskets, which you may have seen described on page 145 of our issue of February 20th. French Plums are sent in deal boxes, differing in size, many being about 2 feet long, 18 inches wide, and 9 inches deep; but choicer fruits are sent in much smaller boxes containing two or three layers of fruit, packed in soft paper shavings, the boxes also being lined with paper, the ornamental or "laced" margin of which is brought very neatly over the fruit, giving to the boxes a very attractive appearance. Some of the smaller of these, a foot in length or less, are extremely tasteful, and not a few purchasers consider them worth more than the fruits they contain.

Cropping Vines (C. G.).—We do not think the owner of the house has any cause to complain about the produce of the Vines since they were planted, and we hope he has not complained. Most persons who have new Vine borders made and Vines planted not unreasonably "expect good crops of Grapes," and we know that in their anxiety to produce them some gardeners have exceeded the bounds of prudence in cropping when the Vines were young. We do not imply that you have done this, as when the fruit finishes well, and the Vines at the same time make satisfactory growth, that shows that they were not exhausted. During the present season you had better not allow any bunches to remain on the weak laterals, but allow them to extend for gaining strength. If you obtain a weight of Grapes, averaging from 1 lb. to 1½ lb. per lineal foot of each Vine, that may be regarded as satisfactory under the circumstances. It is contrary to our rule to recommend dealers in anything. Consult advertisements and catalogues.

Exhausted Vines (S. T.).—As the Vines in the outside border are in such an exhausted state, and you have convenience for making a border inside the house, we should not lose a season in attempting to renovate them, but make a border 3 or 4 feet wide in the house, of good soil, building the front of the border with turves, procure some good canes at once and plant when growth commences, cutting out some of the old and apparently nearly useless rods to afford room for training young canes. It would not be advisable to shorten the young Vines for planting at this season of the year, as bleeding would most likely follow; neither would it be desirable to allow all the buds to grow, as this way you would probably have a great number of very weak laterals. We should rub off the buds down to where it would be convenient for fresh growths to start, and not until these had attained a length of several feet should we remove that part of the canes divested of buds. In this way you may have very good young canes this year and very strong ones the next.

Forced Lilacs (G. H.).—As these cease flowering cut them close back, only leaving one or two eyes on the past season's growth. They should be placed in a cool house to harden and break again into growth, and finally into cold frames. If care is taken many of these plants will make strong growth, and flower freely enough another season. Although it is better to have two batches of these plants and flower them alternately, but those not in this position may achieve success with one batch of plants, but every care must be taken of them after flowering. It is a mistake to give such varieties as Charles X. too much root room, for they grow too strongly, and fail to flower in consequence of the wood being insufficiently ripened. When thoroughly root-bound short sturdy growths only are made, which are certain to ripen if assisted for a time in a frame, and then plunged outside in a warm, sunny, open position. When they have commenced growth they may be top-dressed with a little rich material, and given afterwards two or three applications of artificial manure during the season of growth. Guelder Roses may, after flowering, be subjected to the same treatment; but these are so easily rooted, either from ripened wood or green shoots, so that there is no difficulty in having good batches of plants for alternate years. Without a large supply of flowers are needed for cutting, plants in 5 and 6-inch pots are the most serviceable for decoration.

Steamed Bone Flour (T. R.).—This is the result of grinding bones that have had the fat and a portion of the ossein melted out of them by being subjected to steam pressure and powerful heat in a close boiler. When the bones are thus dried they can be ground into finer particles than new bones can, and the action of the manure is quicker in consequence, notwithstanding that the finer and drier flour may contain a little less nitrogen. Perhaps your best plan will be to dissolve them by either of the following methods as may be most convenient:—1, Place 5 cwt. (or 12 bushels) of bone on an earthen floor, surrounded

by a rim of ashes; pour on as much water as the bones will suck up, and then pour on 2 cwt. of sulphuric acid; it will boil somewhat violently for a while. When this has subsided it will get tolerably solid, and the ashes and all may be shovelled up together, and will be fit for use in a day or two. 2, Take a large watertight hogshead and cover the bottom with about 5 inches deep of dry soil; on this put a layer of bones of the same depth, and cover them entirely with wood ashes; on these another layer of bones, then ashes, and so on till the hogshead is full, placing a good thickness of ashes on the top. Leave it exposed to the rains all summer and winter till spring. Then on removing the contents of the hogshead the bones will crumble to powder under a slight pressure, and form one of the most valuable manures ready for immediate use.

Fuchsias from Seed (W. R.).—We have raised many hundreds of plants from seed, but few of them on flowering proved equal to existing varieties; still the pursuit is interesting to amateurs who desire to have something new of their own raising. The pods should be carefully gathered when ripe. As the seeds are enveloped in a pulp it is necessary, in order to preserve them, to cleanse them effectually. This is done by washing; bruise the berries with the hand, and mix them with water; as soon as the pulp is all washed off pass the liquor through a hair-sieve fine enough to catch the seed, wash it repeatedly till it is quite clean, then dry it gradually; put it up in brown paper, and keep it in a dry room till spring. Sow now in a mixture of light sandy loam and peat, cover slightly, and place the pots in a gentle hotbed. When the seedlings are half an inch high transplant them in rows across pots 5 inches wide—these will hold about twenty or thirty plants each—and then replace them in the hotbed. In these pots they may remain for a month or six weeks, and then they will require placing singly into 3-inch pots. Place them for a few days in a cold frame, and keep pretty close and shaded till fresh roots are formed, and then they are then able to bear the full light, and a moderate admission of air. Give plenty of the latter as they acquire strength, and when the pots are full of roots give another shift into 4-inch pots, and let them remain in these last till they flower. Many of them will flower the first year, and then is the time to make a selection. The selected ones should be repotted, and grown on to the end of the season to prove them. Cuttings of the best may be inserted, and the whole kept in the coolest part of the greenhouse during the winter.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. G.).—The flowers you send being florists' varieties, not species, they do not come within our regulations for naming specimens. See the conditions above. We know of no better chance of obtaining the names of florists' flowers than by sending some to the nursery from whence the plants were purchased. (Herefordian).—The Begonia is glaucophylla splendens, the Orchid is Oncidium Cavendishianum, and the other plant is Cyrtodeira fulgida. (D. C.).—1, Posoqueria multiflora; 2, Spathiphyllum Patini; 3, Paullinia thalictrofolia; 4, Insufficient without flowers; 5, Myrsiphyllum asparagoides. (B. N.).—1, Pinus longifolia; 2, Retinospora squarrosa; 3, Juniperus canadensis. (B. E.).—The specimens are not good ones, but we will endeavour to give them names in next issue if the plants can be identified by comparison with others. (C. H.).—It is one of the numerous species of Eria, probably E. obesa, though the pseudo-bulb is scarcely so large as that is commonly. (X.).—It is difficult to name such scraps, and we can only guess that 1, Lycopodium clavatum; 2, 4, and 5, Asplenium Trichomanes; 3, Doodia aspera; 6, Polypodium pectinatum.

TRADE CATALOGUES RECEIVED.

SPRING PIGS.

As the time draws near when well-managed sows have their first litter special attention may advantageously be given to the subject of swine management now, in order that all which is necessary to promote the health of both sows and pigs may have timely attention. Health before all things say we, for unhealthy pigs are among the difficulties of farming, for which it is not an easy matter to find a remedy, and perhaps the best way to have healthy pigs is to breed all that are required upon the farm, and to avoid the purchase of animals apparently healthy, but which may have the germs of disease in their systems, soon to develop into a contagious disorder that may lead to serious loss.

A well bred, well fed sow is naturally ready for breeding at the age of six months, but many farmers prefer to wait at least two months longer, and some consider the age of ten months altogether best, as the yelts' frame is proportionately larger. Much depends upon treatment, and it usually answers best so to arrange matters that a sow has her first litter by the end of February or early in March, and her second litter in August, as then both litters have the advantage of long days and warm sunshine, under which they

thrive in a manner never equalled by late autumn pigs, for pigs suffer more from cold than any other animal, and so-called bad doers in winter require most of the food they get to keep them alive, the food being just so much fuel to sustain vital heat, hence the importance of well-planned breeding and of snug winter quarters for the pigs.

Spring pigs have all the advantage of weather that is possible in our fickle climate, and a very large proportion of their food will be turned to best account for its legitimate purpose of pork manufacture. It was laid down last month by Mr. Sanders Spencer, of Holywell Manor, St. Ives, Hunts, whose pigs are famous all over the world, that 4 or 5 lbs. of meal, consisting of one-sixth Wheat, three-sixths Barley, one-sixth Peas, and one-sixth Broad Beans will produce 1 lb. of pork if consumed by a fairly well-bred pig of six months old—or in other words, 15 lbs. of meal, costing less than 11d., will produce 3 lbs. of pork, at a cost of less than 4d. per lb. We give this statement because it is perfectly reliable, and also because these are the days of mixed food; but we may remind our readers that our young Londoners, of an average dead weight for the clean carcase of 56 lbs., realise 6½d. per lb. at Smithfield, and the food used is just middlings and maize. Inferior Wheat samples ought certainly to be turned to account for feeding purposes, and there should be no difficulty about mixed food at any farm where a fair proportion of the land is still used for corn growing.

It is a good rule not to keep large sows, but to dispose of them as they approach the unwieldy stage. In a commodious sty, with a moderate quantity of straw, the pigs should take no harm, and we prefer leaving the sow undisturbed. The sow is kept upon sharps and bran for the first month, by which time the pigs begin eating, and they are fed by means of a slip board, outside the sty, with fine middlings mixed preferably with milk thinly, in order that the difference or rather this addition to the sow's milk may not be so great as to cause scour in the pigs. Weaning generally occurs at the end of the sixth week, the pigs being at first shut out from the sow for a few hours only at first, the time being gradually extended till they are entirely withdrawn. After the weaning the diet takes a more substantial form, and the quality of the meal may be improved by mixing any corn set apart for the purpose. With the exception of maize all the corn should be home grown, unless indeed the home-grown corn is of such high quality that it answers best to sell it and purchase other inferior corn. This may frequently be the case, especially among Barleys, but where oatmeal is the staple pig food as it is in Sussex, large heavy home grown corn is preferable, because it has less husk than light imported Oats. Green food and roots, especially Mangolds, is always a wholesome addition to the swine dietary, and a run on pasture should always be continued for sows free from maternal cares, both for the sake of health and green food. Healthy parents may be expected to bring healthy pigs, and they will continue so if due attention is given to cleanliness, wholesome food, and the strict exclusion from the farm of all other pigs that have not a clean bill of health.

WORK ON THE HOME FARM.

All horse stock must now have special care, for there is much risk of colds, sore throats, influenza, and still more serious complaints, while they are under the weakening influence of shedding the coat. An extra feed of corn daily may do much to support the system, and every attention should be given to horses after a journey or long day's work. A cough, accompanied by shortness of breath, should have immediate attention. The horse should go into hospital for a few days, have its throat well rubbed with mustard, and have bran mash with scalded oats, and a powder in the mash night and morning as follows:—2 to 3 ozs. powdered nitre, and 9 to 12 drachms tartar emetic, mixed, and divided into six powders. This is a safe, sure, and very cheap remedy if only the case is taken in time. If more alarming symptoms present themselves at once call in a competent veterinary surgeon, for acute inflammation or congestion of the lungs may quickly cause the loss of a valuable animal. Mares heavy with foal should be worked with caution, but they are all the better for light work, which affords healthy exercise till within a short period of foaling. Then let each mare have a large loose box, and be kept quiet. A pregnant mare near her time ought never to be turned out with other horse stock, as is so frequently

done, for any excitement may lead to the loss of both mare and foal. One of our tenants lost a mare and foal in this way last spring; he then shut up the other mares, and went and insured them! Well, we hope it was a lesson for life; but he had been breeding horses for many years, and ought to have done better. Insure the mares, take proper care of them, and then you need not hesitate to breed. The one thing which can be said against horse breeding is the loss of the mare's work just when horses are so much in request upon the land; but if the arable land is reduced within reasonable limits it may answer to keep some really well-bred mares, for superior horses are certainly profitable at the present time.

OUR LETTER BOX.

Experiments in Agricultural Chemistry (G. E.).—Professor Jamieson's views on agricultural chemistry and the results of his experiments are embodied in a series of annual reports of the work of the Associations for the Improvement of Agriculture, which have for some years been under his control both in Sussex and Aberdeenshire. We believe the reports are only printed for the benefit of members of the Association, and are not sold.

Bone Meal for Pasture (J. J. S.).—Of bonemeal 3 cwt. per acre, and of half-inch bones 4 cwt. per acre is a fair dressing. Your employer is quite right in his preference for the half-inch bones. With a view to permanent benefit, as well as the immediate restoration of fertility in your grass land, which has been mown for twenty years, we strongly advise you to use, in addition to the half-inch bones, 1 cwt. nitrate of soda, and 1½ cwt. of mineral superphosphate per acre. Our first bit of experience of the value of half-inch bones for old pasture was gained some twenty years ago, when we tried them upon a 15-acre meadow in a poor, thin, silicious soil. The effect was good and lasting, for bones decay so slowly that they afford a certain store of food for many years, and it is the finer particles which tell upon growth for the first two or three years. Do not, however, place too much reliance upon the bones. They act beneficially in the soil, mechanically, and as a mild form of fertiliser; but bone-phosphate, the chief mineral constituent of bones, is almost insoluble in water, and the powerful agency of sulphuric acid has to be used as a solvent when we require prompt and full action of this phosphate upon a crop. Therefore use the bones, but also use the soda and mineral superphosphate every spring, only take care to use them early, and the cost of the manure will be returned tenfold.

Oil Cake for Dairy Cows (W. J. A.).—Linseed cake ought never to be used for dairy cows, because it spoils the milk for butter-making by imparting an unpleasant flavour to it, and it also renders a cow liable to milk fever at calving. The best meadow hay, sliced Mangolds, and bran is the best dietary for cows in milk now, 17 lbs. of Mangold and a gallon of bran being given to each cow in the morning at milking time and again at the second milking in the afternoon. For delicate or weak cows a few crushed Oats may be used to good purpose. Hay is given in racks morning and evening, care being taken to use only as much as the cows can clear up at once. If you have a chaffing and mixing apparatus then equal parts of hay and Oat straw may be cut up and mixed with minced or pulped roots. In Denmark, where many dairies are now under constant veterinary inspection, the winter dietary consists solely of hay, straw, Oats, Barley, and Carrots. We use Carrots during the last three months of the year, Mangolds coming into use with the new year, and we proved to our satisfaction long ago that for a strong healthy cow bran is quite sufficient without any corn.

REMARKS.

- 2nd.—Bright with cold N.E. wind and occasional slight snow showers: snow about 1 inch deep at 9 A.M.; ground white all day.
3rd.—Bright and cold, ground white all day.
4th.—Cold with smoke fog all morning, bright afternoon, ground still white in the shade.
5th.—Bright and mild, snow melting rapidly.
6th.—Generally overcast but occasional sunshine, bright night.
7th.—Fine with occasional sunshine in the morning, bright afternoon.
8th.—Wet until about 11 A.M. then generally fine, but heavy showers at 1.45 and 5.30.
Very cold at the beginning of the week, the minimum on the 4th being the lowest recorded in March during thirty years. Temperature of the week, as a whole, about 5° below the average.—G. J. SIMONS.

FLOWER CULTURE FOR PROFIT.

THOSE who are fortunate in possessing a well-established healthy stock of *Eucharis grandiflora* ought to be able to flower these about three times in a year, and to sell the greater portion of the flowers at a highly remunerative price. Being, perhaps, among the most effective that can be used in wreaths and crosses, and of good service in bouquet making, there is always a good demand for these flowers. Seeing, also, that they succeed admirably in a house the roof of which is covered with *Stephanotis*, shade of some kind being in fact absolutely necessary during hot bright weather, there is all the more reason to attempt their culture on a somewhat extensive scale, though, unfortunately, failures will and do very frequently occur. The mite is the great bugbear in *Eucharis* culture, but even this is blamed for more failures than in strict justice ought to be attributed to it. In my humble opinion not a few failures might be traced to mealy bug. No good gardener can long tolerate the appearance of bug-infested plants, but too often the remedy is the commencement of the decadence of the stock of bulbs. The fleshy leaves of the *Eucharis* are most susceptible of injury from any kind of insecticide used sufficiently strong to destroy even a few bugs, and the rapid decay of the leaves is accompanied by an equally bad collapse at the roots. Whether or not the mite were present when the plants were in full vigour, it is very certain they could not make any headway till the plants are much weakened from other causes. Once it has become necessary to shake out and repot *Eucharises*, or other plants of a somewhat similar nature, there is no mistake about the capability of the mite to retard progress and improvement. We have completely skinned and soaked infested bulbs for twenty-four hours in Gishurst compound and other strong insect-destroying concoctions without apparently destroying the mite, and the remedy does not lie in that direction.

All who can successfully defy either the mite or mealy bug rarely if ever fail to grow *Eucharises* in a most profitable manner, and it will, therefore, be understood my remedy for these, and which takes the form of preventive measures, is perhaps the best method of culture in any case. No greater mistake can well be made than to be constantly pulling pots of bulbs to pieces, this being a sure means of preventing free flowering, and, in addition, simply invites an attack of mites. Supposing it is desirable to either increase the stock, to renovate unhealthy bulbs, or to get quite rid of mealy bug, the best course to pursue is that indicated by Mr. H. Porter (page 140)—that is to say, a fresh start should be made with bulbs only, the leaves being cut clean away. I first saw this plan successfully adopted by a friend who wished to thoroughly clear his plants from mealy bug, and I have since tried it for the mite. At the present time I have whole boxes of bulbs and many in small pots that were actually thrown away as being worthless, all attempts to rid them of the mite having failed. It would appear a hard matter to kill them, as after all their rough usage they are rooting strongly, and forming healthy foliage. Another instance has come under my notice where numbers of *Eucharis* bulbs were thrown away into a wood near the garden. They remained there all one winter, then commenced growing afresh, and all were potted again with the best of results. A box of mite-infested bulbs I once sent to a market grower who was convinced he could destroy the mite were, from a cause which need not

be gone into, not delivered for two months. Quite recently I heard that they are now in a very healthy condition, the mite, if present, being quite harmless.

Where many err is in placing several bulbs previously in an unhealthy state in one large pot. This may answer well where no mite exists, but rarely in the case of those in a comparatively weakly state. Our plan, and which we have tried with good results, is to place either one large or three smaller leafless bulbs in a 4-inch pot, plunging all in a fairly brisk bottom heat. Roots and leaves are formed simultaneously, and at this time of year quickly, the pots are soon well filled with roots. Before they become badly root-bound they are shifted into 6-inch pots, and if the growth made is extra strong yet another shift may be given in the autumn. Newly disturbed bulbs are apt to flower soon after they are repotted; but this has a most weakening effect, and the flower head should be pinched off as soon as seen. Kept in a brisk stove heat, not too near the hot-water pipes, though not necessarily plunged in fermenting material, carefully shaded from bright sunshine, frequently syringed and not over-watered, well-established *Eucharises* generally ought to grow strongly and defy the mite. The single bulbs will increase in size, and also form side shoots, a strong pot being eventually obtained. In each and every case an unlimited root run is liable to end in the loss of roots and the ruination of bulbs. The more crowded the pots are with roots the less likely are the plants to fail to flower frequently or to succumb to the mite. Some of the most profitable pots in the country are not disturbed or repotted in any way till they actually burst the pots they are in, numbers of the largest specimens remaining in the same pots five years and upwards. A light loam with plenty of fibre in it best suits *Eucharises*, any in which clay abounds being objectionable. To three parts of the former add one of good leaf soil and coarse sand freely. If the loam available is of a heavy close nature burnt loam and charcoal must be liberally added to the compost, as it is of the greatest importance that the soil remain sweet and porous. It is almost needless to add that the pots should be clean and carefully drained.

As before pointed out, well established specimen *Eucharises* will flower two or three times in a year, the flowering period being to a certain extent regulated by the cultivator. Where many plants are grown it is possible to have flowers, few or many, all the year round, but as a rule they ought, as much as possible, to be most abundant at Christmas, Easter, and other Church festivals, this being when there is a great demand for them. While the plants are growing strongly the heat should be kept up, but when the young leaves are fully grown the most advanced may be transferred to a somewhat cooler house, the temperature ranging say from about 55° by night to 65° in the daytime, or a drop of about 10° all round. No drying off ought ever to be practised, but while resting rather less water will be needed. A rest of from six weeks to two months is sufficient, and all that is then needed is sudden excitement or a considerable increase in temperature to start them flowering freely, and probably in less than a month. During the flowering and growing period weak and clear soot water may be given frequently with advantage, but ought to be discontinued while the plants are resting. Soot is rightly considered a good deterrent of the mite, but it is sometimes of a somewhat fiery nature, and must not be used recklessly.

Prices for *Eucharis* blooms do not vary so much as might be expected, as we have frequently sold them in June and July to better advantage than in the spring and autumn months, Eastertide excepted. A fair average would be 3s. per dozen (thirteen ought always to be sent), but if they can be consigned in moderate quantities direct to florists the average would be nearer 4s. The lowest price we have booked is 2s. 6d., and the highest 6s. per dozen. Seeing that a strong pot of bulbs will annually produce not less than thirty spikes, and not unfrequently double that number, from four to six flowers being

borne on each scape, I think I am justified in placing Eucharises in the front rank of profitable flowers. As a rule far too much fuss is made in packing the flowers for transit. We merely line a shallow fancy soap box for sending a few, and a thin mustard box for larger quantities, with either soft dry moss or cotton wool, this being covered with tissue paper. A small piece of well moistened cotton wool is wound round the short footstalk of each flower, this being most necessary in warm weather, and all are packed closely together face upwards, being then covered with a sheet of tissue paper, over this a layer of cotton wool, on which the lid closes tightly. The flowers cannot shift, and we have never had a complaint of their travelling badly. Small boxes are sent by post, heavy ones by rail. It is useless to send stale flowers. All should be gathered directly they are fully expanded, and placed in a cool room till they can be sent away.—M. H.

BLENHEIM PIPPIN AND OTHER APPLES.

BLENHEIM Pippin is undoubtedly one of our very best Apples, and its fruit is entirely worthy of the high estimation in which it is so generally held, for in it we have a remarkable development of every characteristic of the best market fruit—large size, handsome shape, high colour, and with this is combined the intrinsic merit of rich-flavoured juicy flesh. But alas! the noble fruit is almost as rare as it is rich, and it was with a feeling little short of downright amazement that I saw this Apple recommended repeatedly in the *Times* and other newspapers as a leading sort for profitable fruit culture. No doubt the fruit commands a brisk sale when you can get it, but that is just the point—it is a shy bearer, not only as a young tree but in its prime. I have tried it in every way—as a standard, bush, pyramid, and espalier; in a deep natural loam, in specially prepared soil on different stocks, and in different counties; but nothing which I have done, or have seen done by others, has had any material influence upon its barren nature.

It was in the year of the great comet in the fifties that I had a standard tree of it in a grass orchard, heavily laden with splendid fruit, several bushels of which was stolen off the tree one night by some rogue, whose judgment was better than his principles. That orchard was in my hands for the next six years, but I never had another crop of fruit on the Blenheim Pippin. Since then I have seen a few good crops of it, and have more than once heard the owner of the fruit boast of his good fortune in having for once got a crop for such a rarity. I tried it in Sussex, both on the free stock and the Paradise, but failed to obtain fruit during all the years (some fifteen or sixteen) that the trees were in my hands.

These trees were part of a large selection of sorts, common and uncommon, made for me by Dr. Hogg, and among them was an Apple named Cobham, the fruit of which bears so close a resemblance to Blenheim Pippin that it only requires a little more colour to pass muster as a veritable Blenheim. It is quite as juicy, is as rich in flavour, the flesh is more tender and sweet, the fruit keeps good longer, and, what is more to the purpose, it comes freely upon the trees when they are quite young, so that it proved entirely worthy of its character of an early and abundant bearer. The tree grows with such vigour on the Paradise stock that it soon attains to a large size, and from its vigour and fruitfulness is worthy of a place with such fine sorts as Warner's King and Lane's Prince Albert as a capital substitute for Blenheim Pippin.

Cox's Orange Pippin is rightly regarded as a substitute for Ribston Pippin. It has also been recommended as a substitute for Margil, which certainly is a mistake so far as my experience goes, for I have found Margil on the Paradise stock a sure bearer, yielding fruit early and abundantly, and if possible the trees become more fruitful with age, the spurs being crowded with blossom buds, the wood growth being perfectly healthy without a trace of canker. Planted in the same soil, Cox's Orange Pippin on the Paradise made magnificent pyramids and bush trees, and there were equally fine espaliers of it on the free stock, but where it had one fruit Margil had a bushel, so that I for one am bound to give Margil preference, both for the home supply and for market. It ought certainly to hold an important place in profitable fruit culture.

To show how difficult it is to recommend Apples for general cultivation I may mention Court Pendu Plat, of which there were several fine standards in the grass orchard which I have mentioned. They were uniform pictures of health, and generally had an abundant crop of fine fruit, the production of which is all the more certain from the late flowering habit of the tree. These trees were in the deep rich loam of the Cherry orchard district of North

Kent, but some others which I subsequently planted in Sussex became so crippled by canker as to be worthless. In the Kentish loam Red Astrachan answered perfectly, and I know nothing more beautiful among Apples than its deep crimson fruit covered with a delicate bloom, but I could do no good with it in Sussex, where the trees certainly grew freely and were healthy, but they never had a fruit. This was in the ironstone district, where much of the soil contained so much oxide of iron that fruit which thrives in it has very highly coloured fruit, and I retain a lively remembrance of the magnificent appearance of some trees of Fearn's Pippin in full bearing, every branch being crowded with handsome glossy crimson fruit.—E. L.

PLANT HYBRIDISM.

[A paper by Mr. Lewis Castle, read at the Horticultural Club, March 11th, 1890.]

No subject connected with horticulture presents so many features of interest and importance as plant hybridisation; it has been closely studied by some of the best observers and most skilful practitioners, numberless facts are recorded bearing upon the matter, and extraordinary results have been achieved. To review the results alone would require a large volume, but to provide matter for discussion it will only be necessary to touch upon a few points, and detail observations or experiments illustrating them.

It must, however, be premised that it is exceedingly difficult to draw up any general rules, as what is found to hold good in one family, or even in one genus of plants, does not apply with the same force in others, and where any general principle can be defined the exceptions are often so numerous that its value is considerably diminished. This no doubt is mainly due to the impossibility of providing identical conditions in every case, and also to the fact that though so much is known regarding plant-fertilisation there are still many mysteries or seeming anomalies to perplex investigators. Fortunately in certain marked groups of plants—sometimes merely the varied descendants of one species—hybridising or crossing has been reduced to a system, and after long experience those engaged in the work can predict with some approach to accuracy the probable results of their experiments. With an extension of such methodical observations we may expect much which is now obscure will be ultimately elucidated.

INFLUENCE OF POLLEN AND SEED PARENTS.

One portion of the subject which merits especial attention is a consideration of the relative effects of the pollen and seed plants employed as parents in the production of hybrids. We have to deal with some of the principal phenomena of plant life, and the results of the innumerable experiments would appear to give us good foundation for definite rules. This, however, is far from being the fact, and we can only generalise in the majority of cases. In the Orchid family perhaps hybridising has been reduced more nearly to a system than in any others, and the number of reversed crosses exactly resembling the product of the original cross is so great it points to the conclusion that the pollen and seed parents have but little special effect. One of the most skilful and successful of Orchid hybridisers writes me on this subject as follows:—"In no case can I see one hybrid but what is quite intermediate in habit of plant and shape of flower, though in some cases out of the same seed pods we get variety of colours. In every case if possible we take the strongest plant for the seed parent. We always have an object, but in some cases are disappointed, and those concerning which we are most hopeful are often the most disappointing. Some hybrids, particularly in the *Cattleya* family, even before flowering are exactly intermediate in habit between the two parents, that any person who knows the family well can read the parents in the plant. Take *Cypripedium Sedeni*, for example, from *C. Schlimi* crossed with *C. longifolium*, and the reversed cross. These are so nearly alike that we cannot distinguish one from the other; habit of plant, time of flowering, leaves, length of flower-stem, shape and colour of flower, are all the same."

An example of this fusion of characters was afforded at a recent meeting of the Royal Horticultural Society, when plants of the hybrid *Cypripedium Lathamianum* were exhibited from *C. Spicerianum* crossed with *C. villosum*, and from the reversed cross the results were practically identical. In a few instances the reversed cross has resulted in something of a slightly different character, as for example in *Zygopetalums*, *Z. pentachromum* having been raised from *Z. Mackayi* crossed with *Z. maxillare*, and *Z. Sedeni* from the reversed cross. In the majority of instances, however, there is a fusion of character that is rarely seen in other plants.

The term hybridising is now usually confined to the fertilisation of one species by the pollen from another, and crossing to the same operation effected between varieties of one species; the latter

term was, however, at one time applied to the reverse crossing already noted, and hybridising is a sufficiently general term to be fairly applicable to either case. In *Primula sinensis* and its numerous forms we have examples of extreme variation artificially produced without the aid of another species, but the variations obtained under cultivation are so pronounced that crossing has been resorted to with surprising results in increasing the number of forms and tints. One of the largest cultivators of these and some similar plants assures me in making crosses between two varieties of *Primula sinensis* he always expects the seed parent to give three out of every four characters, and it is this fact which renders it difficult to produce distinct alterations in any type, as it is only either by chance or by a long series of experiments that a desired result can be secured. Another hybridiser who has been engaged for some years in the production of *Primula* seed, has found that the seed parent generally gives the foliage and habit, and the pollen parent the floral colour. With regard to this I proved from experience a few years since that in crosses between the "Fern-leaved" and "Palm-leaved" varieties, when the former was made the seed parent there was a much larger per-centage of seedlings with "Fern leaves" than if the pollen was used on the "Palm-leaved" varieties, thus supporting the opinion just given. It has also been observed with regard to *Primula sinensis*, that the pollen from a double variety placed on a single variety was more likely to give a good proportion of double flowered seedlings in the progeny than if the parentage were reversed. As an example of that the pollen of an excellent double variety with flowers of a moderately good crimson colour was employed to fertilise a single variety of an exceptionally bright tint, and the result was a double variety with flowers equal to the pollen parent in form and substance and as bright as those of the seed parent. As exceptions to this, however, it must be noted that in two instances where doubles have been crossed on singles, all the seedlings came single, and in the reverse cross about 10 per cent. were double.

In experiments with Balsams I have found somewhat similar results to those described—namely, pollen from a single flower applied to a double flower produced a much larger per-centage of double-flowered seedlings than where the single variety was made the seed parent; but when pollen could be obtained from another plant of a double variety for application to the double seed parent the result was still more satisfactory in the number of double-flowered plants produced, though the colours were often less bright than in the parents, and this loss of colour was not so noticeable when a single-flowered pollen plant was employed.

With Zonal Pelargoniums I made a number of experiments some years ago, partly with the object of testing the relative effects of the respective parents, and though the results were somewhat diverse, yet amongst hundreds of seedlings raised quite 80 per cent. more closely resembled the seed parent in habit and foliage, and the pollen parent in flowers. Mr. Peter Grieve, who performed good service amongst the variegated Pelargoniums, has stated that in his opinion the constitution of a plant is chiefly due to the seed plant, and he attributes the delicacy of many of the Pelargoniums named to the employment of the plants with variegated leaves as seed bearers. He further says, "The most vigorous and in all respects the best I have raised have been from green-leaved seed parents." This we can easily understand, but my observations teach me that considerably more depends upon what may be termed the individual characters of the seed plant than upon the specific or varietal distinctions. Thus the selection of a healthy plant for seed-bearing is likely to give better results than a weakly individual of the same species, whatever the cross may be.

It has been stated with good reason that where so much difference results from reverse crossing it is in a large measure due to diversities of form or constitution of the pollen, and in some of the most variable cultivated plants the microscope reveals a surprising variation in the form of the pollen grains. Certain plants, however, possess an inherent capacity for variation through a greater range than others, and in two that have been noted—i.e., *Primula sinensis* and the Balsam, all the forms have been originated by intercrossing without the aid of other species. Phlox Drummondii might be cited as another instance of a similar kind, all the variations having been formed within the limits of one species. It appears that under cultivation the constitution of a plant gradually becomes disturbed; different soils and conditions, with perhaps increased vigour, produce effects that are most likely to be felt in the delicate floral organs, though probably more evident in the foliage and growth. To increase the tendency to variation, therefore, plants should be grown under as diverse conditions as possible consistent with their health, and when the crossing is confined to the forms of one species the most distinct should be selected, except where some particular character is desired, when close in-breeding will sometimes produce the wished for result.

PARTIAL FERTILISATION AND STERILITY.

Hitherto attention has only been directed to plants in which there has been little difficulty in securing seed; the progeny have presented a fusion of characters more or less complete, and have been equally fertile, or nearly so, with their parents. Next to these we have the hybrids or crosses, which are themselves either partially or wholly sterile, except when fertilised with pollen from another variety or species. Examples of this occur in nearly every family of plants where hybrids have been produced, and even amongst the descendants of one species, as in the highly bred forms of *Primulas* previously mentioned, *Cyclamens*, and other plants. In some of the brightly coloured single *Primulas* much difficulty is experienced in securing seed for this reason, as even when abundance of pollen is produced, as happens occasionally, it seems useless except when employed on other varieties. Close intercrossing often induces sterility in the seedlings, and is commonly attended by a greatly increased vegetative growth; a consequence as some suppose of the sterility, but probably in certain cases it is the cause, for it is well known that excessively luxuriant plants are rarely such good seed bearers as those of a medium or even stunted growth. There is another form of partial sterility, this time in the parent plants, when perhaps it is possible to make one plant the seed parent in a cross, but not to reverse the cross and secure seed. Something after this kind took place in the production of the hybrid *Rhododendron* Princess Alice, which was obtained by two cultivators from *R. ciliatum* fertilised with pollen from *R. Edgeworthii*, yet Mr. Anderson-Henry has stated that he repeatedly tried to secure seed from *R. Edgeworthii* by employing pollen of *R. ciliatum*, but failed every time.

Sometimes in the results of hybridising one species with another some of the seedlings show altered characters partaking of the two parents, and others closely resemble one only of the parents. A peculiar instance of this kind has been recorded, in which *Begonia manicata* was crossed with *B. coccinea*, and one pod of seed was produced. Seedlings were raised, and amongst them were two distinct forms that were afterwards named *B. prolifera* and *hybrida*, but a large proportion were the true *B. manicata*. In this case it would seem that either the pollen of *B. coccinea* had sufficed to impart vitality to the ovules without altering their character, or that some of the ovules had been self-fertilised, either being equally remarkable.

IMPERFECT FERTILISATION.

The last form of fertilisation that need be considered here is that in which the pollen only influences the ovary to induce an enlargement, the ovules not being affected in any degree, or not sufficiently to render them fertile. Dean Herbert recorded many instances of this kind, and amongst them he mentioned that when *Alstroemeria aurea* is fertilised with pollen from other species full sized capsules are produced, but no perfect seeds. Fruits have been obtained on *Passifloras* in the same way, but seedless, and numbers of other instances could be given.

Turning to the Orchids we have as regards the *Odontoglossums* two curious facts to consider. One is that numbers of *Odontoglossums* are found in a wild state so exactly intermediate in floral form and colouring between other well known species as to leave no reasonable doubt that they are natural hybrids; they have been introduced freely, and have puzzled botanists and horticulturists not a little. The other fact is, that notwithstanding this evident variability and tendency to intercrossing in a wild state, the *Odontoglossums* have not yielded to the cultivators' attempts to obtain hybrids under artificial conditions, indeed they have stubbornly resisted all efforts, and have caused more disappointment than any other Orchids. Seedlings have been raised in a few instances, but invariably lost, and the strangeness of this circumstance induced me a few years ago to make some experiments with a view to testing the matter. I had several healthy plants of *Odontoglossums*, and amongst them were six each of two favourite species—*O. Pescatorei* and *O. triumphans*. They were in good condition for experiment, flowered well, and if a cross could be effected they gave a promise of something worth securing. Yellow forms of the *O. Pescatorei* type had been introduced, and one charming variety, for which Mr. Brownlow D. Knox obtained a first-class certificate from the Royal Horticultural Society on April 13th, 1886, impressed me greatly, and the impression was intensified when the same plant realised £165 at a public auction the next day. There was little doubt that *O. triumphans* or *O. tripudians*, most likely the former, had conferred the yellow colour, and it did not seem too much to expect similar results from an artificial cross. Three of the strongest plants were selected of *O. Pescatorei* and of *O. triumphans*, and two flowers of each were reciprocally fertilised—i.e., the pollen of *O. Pescatorei* was placed on *O. triumphans*, and *vice versa*, thus twelve flowers were fertilised, and to my great

satisfaction it appeared to be effectual with nine, for in the course of a week the ovaries were perceptibly enlarging. They were carefully watched, and as they slowly advanced golden visions began to rise of a few thousand yellow flowered plants of *O. Pescatorei*, and these hopes were sustained for nearly six months, when the capsules, which were then well developed, commenced shrivelling, and upon examination were found to contain nothing in the shape of fertile seed.

With the other plants of the two species named a different experiment had been tried—namely, seven or eight flowers were fertilised with their own pollen or with that from other flowers on the same spike, but in only one case was the ovary in any way affected—*i.e.*, where a flower of *O. triumphans* had been fertilised with pollen from another flower on the same plant, and in this instance the development only lasted for a week or two, and the capsule then collapsed as in the previous case. These experiments were interesting as proving what Darwin and others have recorded—namely, that pollen often has the power of affecting the ovary, though it cannot influence the ovules, and cases have even been described where the ovules too have been effected, but no embryo produced. Experiments were tried with several other *Odontoglossums*, but without success, except in one instance, between *O. Cervantesi* and *O. Rossi majus*. A flower of the former was fertilised with pollen from *O. Rossi majus*; on March 29th, 1888, a capsule was produced, which slowly developed and ripened until June 30th, 1889, when it commenced dehiscing. The pod was then removed, and was found to be packed with minute seeds, which when examined under a glass appeared to be perfect. In the course of the following week the seed was sown, and now a few diminutive seedlings are just visible. The reverse cross failed to produce any result, and in any case the seedlings from such parents are not likely to possess any special merit even if they survive, which is doubtful.

The subject is a tempting one to pursue still farther, but I have said enough, perhaps too much, and I will now leave it to others to extend the hints I have attempted to furnish.

REGRAFTING ORCHARD TREES.

THE advice sometimes given in respect to totally removing trees of inferior varieties might well be modified in favour of the plan of cutting back and regrafting with superior Apples or Pears, as the case may be. In this way whole orchards might be gradually improved in character and value without the loss of a season. It is not advised to cut large trees hard back to near the trunk, but the greater portion of medium sized branches may be sawn cleanly off, when all danger of severe frosts is past, to near the main limbs, and each be eventually grafted with a fresh variety. The more fresh grafts there are inserted all over the trees the quicker will a full bearing state be arrived at. Such measures should be promptly decided upon, in order to be well in advance instead of a few seasons behind the numerous orchards recently formed in this country. Not till the sap is rising should the grafting be done, though the stocks may be prepared in advance of this, while the scions or grafts ought to be taken off the parent trees now or very soon, in order to retard the movement of sap, as it is necessary for them to be a few days behind the stocks. The strong branches of superior varieties cut from vigorous trees now being pruned ought to be saved, kept separated, labelled, and bedded in moist cool ground till they are wanted for grafting purposes.

The selection of varieties for grafting on other trees ought, to a certain extent, to depend upon circumstances, or whether the produce is required for home consumption or for marketing purposes. In the former case a constant succession may be desirable, but for sale the early and late varieties are usually found to be the most profitable. It is useless to attempt to sell Apples at a time when nearly every owner of a garden or orchard has abundance and to spare, this being principally in September and October. Therefore regraft inferior varieties with Lord Suffield, Keswick Codlin, Stirling Castle, Cellini, Ecklinville Seedling, and Cox's Pomona, these being heavy cropping, large fruited, culinary varieties, that can be sold readily direct from the trees; and of dessert varieties, to be similarly sold, the best are Worcester Pearmain, Red Joaneting, Mr. Gladstone, Beauty of Bath, Kerry Pippin, Irish Peach, Red Quarrenden, and Summer Golden Pippin. The most valuable keeping culinary varieties are Warner's King, Grenadier, Loddington, Lane's Prince Albert, Wellington, Beauty of Kent, Tom Putt, Reinette du Canada, Lady Henniker, and Annie Elizabeth; while Blenheim Orange, King of the Pippins, Cox's Orange Pippin, Bramley's Seedling, Sturmer Pippin, and Court Pendû Plat are excellent dessert Apples for storing, high prices often being obtained for them during the winter. The following are good orchard Pears, and might well be grafted on inferior stewing

or perry sorts:—Doyenné d'Été, Jargonelle, Williams' Bon Chrétien, Hesse, Beurré d'Amanlis, Souvenir du Congrès, all to be sold direct from the trees, and Durondeau, Pitmaston Duchess, Duchesse d'Angoulême, Louise Bonne of Jersey, Beurré Superfin, Beurré Hardy, Eyewood, Beurré Clairgeau, Beurré Diel, and Beurré Rance, all of which must be stored for a time.—W. I.

[This is the first time we have seen Bramley's Seedling described as a dessert Apple, though we know some persons enjoy it in an uncooked state.]

VANDAS AND THIRPS.

VANDAS, *Aerides*, and *Saccolabiums* are soon injured by fumigation with tobacco to eradicate thrips. The employment of strong tobacco smoke often accounts for their pale green, sickly yellow appearance. If thrips appear, whether yellow or black, it can be destroyed without recourse to such treatment. We lift the plants attacked carefully, a small cloth is placed over the moss to prevent active insects entering it. The plants one at a time are placed at one end of a tank in a sloping direction in which is a solution of tobacco. The plant is shaken or tapped gently; many of the insects fall into the solution below. Tobacco powder is then dusted into the axils of all the leaves, as well as the heart of the plant. The cloth is shaken into the tank and placed on another. If the plants are stood by themselves and carefully attended to for a few days this troublesome pest can soon be destroyed. The powder at the end of two or three days should be thoroughly washed from the axils of the leaves, and especially from the centre of the plant, being careful not to injure any of the foliage.

MOSS FOR POTTING FROM COLD SHEDS.

It is a mistake to leave moss in cold sheds until it is needed for potting and top-dressing. What is wanted for the day's work, whether of peat or moss, should be placed in the structure in which it is to be used the night before. If it is not laid too thickly together it will be thoroughly warmed by the morning ready for use. Slight checks often result from carelessness in having the potting material many degrees colder than the temperature of the house in which the plants are grown. A good supply of moss should be picked and cut in readiness, so that it only needs carrying to the place where the plants are to be repotted. Some trouble is required to eradicate slugs which are introduced with the moss. We take the precaution of spreading out thinly a good quantity on the floor of the house, and then give it a thorough soaking with water at a temperature of 200°. The moss is then left to dry again, which it quickly does if a suitable place is selected for it.

We spread it on a path below which are some of the main pipes, and it dries quickly again and is ready for use. Even with this treatment we have not succeeded in clearing out all the slugs or their eggs. They have appeared shortly after potting, but by a soaking of hot water hundreds have been driven out at different times. Sometimes the moss is much more infested with slugs than at other times. Almost constant attention is needed to eradicate slugs after potting, but if this is done a good deal of trouble and annoyance during the remainder of the season is avoided.

PLACING THE ROOTS IN POTS AND BASKETS.

Beginners in the culture of these plants often try to compel the roots to enter the material provided for them. Those that manage for the time to flourish outside the pot or basket are frequently broken and destroyed by cramming them amongst the compost during the work of repotting or rebasketing. We have often seen plants in this condition, and have turned out many that have undergone this treatment, with the result that the bulk of the roots had perished. Vandas, *Aerides*, and *Saccolabiums* especially delight in having their roots in the moist atmosphere of the house. It is a mistake to try and compel the plants to confine their roots to the limit of the pot or basket. These plants vary considerably in their method of rooting and the quantity they make. If we examine two *Aerides*—namely, *A. Lobbi* and *A. virens*, we find the former inclined to root within the basket or pot to a large extent, a few roots only extending beyond. In a pot this plant is more inclined to push its roots outside than when growing in a basket. This is undoubtedly due to the roots being more fully exposed to air and the moist atmosphere of the house

than those in a pot. *A. virens*, whether in a pot or basket, will have its roots outside. Good healthy plants 18 inches high in baskets will often have roots 4 feet or so in length. Plants in this condition are, as a rule, in the best of health and grow freely, root abundantly, and flower profusely. Those throwing out their roots in abundance in the atmosphere should be grown in baskets where they can be suspended. When grown in pots their roots are always liable to injury.

PLANTS THAT HAVE BECOME BARE AT THE BASE.

Plants of both *Vandas* and *Aerides* may often be seen bare at the base of the stems. Sometimes one or two suckers start, and these should be carefully preserved until the top portion of the plant can be removed. Before this can be done the bare stem must be bound with sphagnum moss up to the leaves and kept moist. This assists the plant wonderfully in making roots above, and when a good portion has been made the plant may be cut off just above where the suckers have issued, and the bare stem can be removed and the top potted or placed in a basket. The top should be taken off just preceding root action and growth. If treated similar to healthy imported plants they will soon establish themselves and grow freely before the end of the season.—ORCHID GROWER.

NOTES AT FOREST HILL.

MESSRS. J. LAING & SONS' nurseries at Forest Hill are always worth a visit, and though their great season is "the Begonia time," yet there are so many specialties, all equally noteworthy, that some attraction is sure to repay a caller. In the spring months the bulbs and forced plants are in strong force, and they have now been rendering several houses gay for a long time. Excellent *Primulas* also have occupied considerable space; *Imantophyllums* are advancing, and the collection, which is being enriched by numbers of home-raised and introduced novelties, is a remarkable one, the plants all in superbly vigorous health.

TUBEROUS BEGONIAS.

The Tuberous Begonias are in a very youthful stage at present, and needing all the experienced care of Mr. Laing's skilful growers to bring them to their annual state of perfection. It is surprising what strong plants can be obtained from seed in a few months by due attention and the best culture. When sturdy hushy specimens are planted out in the summer, to be in a few weeks covered with brilliant flowers, it seems scarcely possible that they could have been raised from seed in the same year. Yet there we see them, tiny seedlings in various stages, being pricked out from the seed pans into larger pans, to be afterwards potted, and then transferred to the grounds or reserved to adorn the houses. Everyone knows what has been done with Tuberous Begonias at Forest Hill. The record is a triumph of the hybridiser's skill, and the still rapidly extending popularity of the plants has been well earned. A large piece of land has been prepared for the Begonia beds this year, and I cannot say how many thousands of plants will be needed to fill the space and supply the demands, the number certainly must be a very large one. Garden owners and cultivators are beginning to find the merits of Tuberous Begonias for hedging purposes, and their decorative value under glass has been abundantly proved.

CHRYSANTHEMUMS.

Another great feature is formed by the Chrysanthemums, which seem to be scarcely less numerous than the Begonias; at least, several houses are filled with a series of long frames, the young stock of all the leading varieties being extremely large. Messrs. J. Laing & Sons have been fortunate in past years in raising some seedlings of great merit, which have already taken a high place amongst exhibition varieties. With the hope of continuing their success they have obtained a quantity of seed from various sources, and now some hundreds of healthy young seedlings are advancing satisfactorily, and will be watched with much interest. There are, however, a few seedlings that receive especial attention and are of unusual importance. These have been raised from seed of the Japanese variety *Edwin Molyneux*, ripened at Forest Hill, and it is scarcely necessary to say that the plants will be reared with all possible care, and it may be fairly expected that should they reach a flowering stage Mr. Laing will amongst them secure a prize worthy of the centenary year.

Most of the members of the Laing family have been honoured by Continental raisers in the names of the Chrysanthemums sent out in recent years; but in some notes a season or two since I pointed out an unaccountable omission. M. Délaux has now completed the family, and has announced Madame Rose Laing as a distinct novelty of the Japanese type. The variety has been described in a continental journal as charmingly attractive; the florets flat, rosy crimson and white, tipped with gold; the tints darken at the centre of the bloom, and silvery white towards the centre of the florets, a novel colouring quite distinct from other varieties.

ORCHIDS

The collection of these plants steadily increases, all the most useful species and varieties being added, and they thrive well in the Stanstead Park houses. *Dendrobiums* are excellent, particularly *D. Wardianum*,

which makes usually strong pseudo-bulbs. *Cattleyas* have been furnishing a fine bank of flowers for some time past, and one grand variety of *C. Trianae* was certificated at the last meeting of the Royal Horticultural Society. Cool house Orchids, especially *Odontoglossums*, are well grown, and good varieties of the principal species are included.

Respecting the large miscellaneous collections—*Caladiums*, *Camelias*, *Lapagerias*, &c.—it is not necessary to say much now, but one little plant that has been flowering through a good portion of the winter (*Acacia ovata*) deserves a special note. A small spray of this is represented in the woodcut (fig. 31), which shows its characters fairly. It is most useful for culture in 48-size pots, being of dwarf hushy habit,

FIG. 31.—ACACIA OVATA.

and producing its bright yellow flower heads freely. The plant is easily grown, readily forced, stands well, and is altogether exceedingly useful, being more graceful than the early *Acacia platyptera*.—L.

LANDSCAPE GARDENING.

[Read at a meeting of the Cardiff Gardeners' Association by Mr. Kettlewell.]

(Continued from page 225.)

I NOW come to the second portion of my paper, and that is to offer a few remarks about some of the leading departments in a garden, and I will begin by giving a few suggestions as to the flower garden. A flower garden, or if there be no flower garden—the flower beds, should be situated on the warmest and most private side of a house facing the drawing-room windows, as the beds give an air of beauty and gaiety in summer when filled with masses of brilliant flowers, while dwarf evergreens, which have been kept in pots and plunged during the summer in some reserved nook in the kitchen garden, can be most effectively

and successfully utilised to take away the bareness which a flower garden or flower beds have in winter. It is surprising what a pleasing effect can be obtained in flower beds by the careful arrangement of shrubs in pots, and with what little trouble and expense, since they only require repotting once a year, and watering a little during the driest part of the summer. If this mode is not adopted a good effect can be obtained during all seasons of the year, whether the beds are filled with masses of brilliant flowers during summer or bare during the winter by the judicious distribution of dwarf specimen evergreens.

Perhaps at this point in my paper the list of a few shrubs suitable amongst others for one or both of the modes above mentioned may be of some interest and value to my readers:—*Andromeda floribunda*, *Yucca gloriosa*, *Erica carnea*, *Rhododendron hirsutum*, the variegated Yew, the variegated *Aucuba*, *Retinosporas*, the Tamarisk-leaved *Savin*, *Pernettya mucronata*, variegated *Euonymus*, *Hollies* of kinds, and *Gaultheria procumbens*.

The beds of a flower garden should be symmetrical and correspond. The more simple the shape of the beds the easier are they to keep in order, and the better for exhibiting the arrangement of flowers. No beds should be made too large, as they then become difficult to attend to; nor the space between too narrow, lest they become in time inaccessible or the flowers in the beds intermixed. Grass laid evenly in broad strips 2 feet 6 inches to 3 feet in width is the most effective division between flower beds, as it sets off the colours of the flowers best and imparts an air of unity to the whole design.

Flower beds ought never to be scattered at random over a lawn, but should always form some regular figure, except in the case of a few beds by the side of a walk. In designing a flower garden, regular figures such as squares, ovals, circles, parallelograms are much more effectively and easily filled, though the ground, by a judicious distribution of beds, can be adapted to almost any shape. In conclusion, one golden rule should always be borne in mind by practical designers of a flower garden, and that is that the chief object of a flower garden is "to display flowers to the best advantage;" however ingenious, however tasteful a design may be, unless this golden rule is strictly adhered to it is of little or no worth.

ROSE GARDENS.

I now come to the second leading department in my list, and this is the rosery, or Rose garden. In gardens of medium or large size Roses are often collected together and placed in a small separate space. This should be in a sunny position, but sheltered from the wind as much as possible, and severed from the lawn and the rest of the garden by a screen of shrubs, as it is as uninteresting in winter as it is brilliant in summer. The design of a rosery should be of some regular shape, the beds simple yet bold in their outlines. Circles, oblongs, ellipses, are perhaps the most useful. As regards the beds of the figure, on no account should acute angles or corners be allowed, as portions of the beds would be practically rendered useless, and the whole design or figure would appear meagre to the eye. Moreover, few plants could be inserted in them, and those but imperfectly. The beds at the same time should be sufficiently narrow, to allow the centre plants to be easily reached from either side of the bed, and for this reason oblong beds with the ends rounded off are perhaps the most suitable. The greater the simplicity of the beds of a rosery, as in a flower garden, the more suitable are they for showing off the Roses.

With reference to the walks of a rosery, the path round the outside of the figure should be of gravel, while the divisions between the beds of the figure should be of grass, 3 feet to 4 feet in width, or of gravel with Box edging, so that admirers of these beautiful flowers may easily examine or pick them. Grass, however, will always look better than gravel, and when it is used not more than one or two cross walks of gravel and an encircling one will be necessary. Great effect can be obtained by throwing across a walk at the entrance to a rosery a light covered archway made of wire, with some of the more beautiful climbers trained up it. Another most effective, and at the same time uncommon adjunct to a rosery, is a Rose house or temple. This is a structure having a light span roof, glazed nearly down to the ground at the sides, with ample facilities for ventilation, and if possible pipes for heating it in winter. Light iron pillars or arches can be erected inside for the support of the more tender climbers, and beds can be formed inside to receive and cherish the Tea-scented and other tender Roses. Before passing on to the next important department in a garden I would say that it would be an invidious task to attempt to give a list of Roses, considering that you all probably know many more kinds than I do myself; but I would make this suggestion, that a very pretty effect can be obtained by placing one class or tribe in each bed, such as beds of

Provence Roses, Hybrid Perpetual Roses, Hybrid China Roses, Bourbon Roses, Moss Roses, or Noisette Roses.

KITCHEN GARDENS.

I should like now to say a few words on that most necessary department, the kitchen garden. Where practicable this should be within easy and direct communication of the rear of the house, and on no account—except in peculiar cases, such as town gardens—should it be necessary to go through the pleasure grounds in order to reach the kitchen garden. The reason of this is simple. The kitchen is generally at the back of a house, and the kitchen garden exists for the purpose of supplying vegetables and other necessities used in the kitchen, and should therefore be as near it as possible. The stables should also be near, so that the refuse and manure may be readily carted to the ground.

Perhaps the best shape for a kitchen garden is a parallelogram, the longest sides being from east to west in order that a greater length of wall facing south may be obtained. Any regular figure, if a parallelogram is not practicable by reason of either the space available or the formation of the ground, is the most suitable for convenience sake; the walks, beds, and borders being in straight lines as much as possible and at right angles to each other. Every kitchen garden should be walled in at least on three sides; firstly, in order that it may be warmer; secondly, in order that the walls may be a means of growing many of the better kinds of fruit trees. The wall facing south should be built to a height of 12 feet with a coping projecting over 3 or 4 inches, the side walls the same height or a little lower, the wall facing north, if there is one, 5 or 6 feet. If, however, an entire enclosure is thought unnecessary, a hedge of Box or Yew kept to the uniform height of 6 or 7 feet will prove more picturesque.

A border all round the inside of the kitchen garden is requisite, varying according to the size of the garden, from 6 to 12 or 14 feet; these borders, however—and this is a matter very little thought of—should not have more than 3 feet of rich alluvial soil, as they then become unsuited to the growth of fruit trees since the roots pass away too far from light and air, two essential requisites to the healthy growth of a plant. A good plan is to place a layer of stones or rubbish below that depth. Perfect drainage is a matter of the utmost consequence in a kitchen garden, and one that must be also thought of if fruit trees or vegetables are to be grown with success.

As a good deal of water is often required in a kitchen garden an open cistern or ornamental tank is advisable, or a pump with an open cistern, as water is much more suited for plant life after being well exposed to the action of the atmosphere. At the back of the garden, or in some out of the way place close to the kitchen garden, there should be one or two sheds for tools and other uses, and a small yard accessible to a horse and cart for rubbish, manure, and the various composts used in planting.

The next important question to which I would call your attention is that of water. This is an element of great beauty in a garden when treated with taste, and adds life with a certain degree of dignity to the scenery. In forming small sheets of water in a place of limited extent simplicity again should always be studied. Circular or octagonal basins, with or without fountains, are perhaps the best in formal gardens, while in the mixed or gardenesque style, where a closer approach to Nature is sought, roundish or oblong pools are the most suitable. If, however, larger sheets of water are being treated—and now we come to lakes—then the shape may be more varied and irregular, so that the whole may not be seen at the same time, and by a tasteful treatment of its terminations considerable indefiniteness may be obtained. Numerous or unnecessary curves or bays are, however, decidedly out of place, as they destroy the appearance of breadth except in large lakes, where a much bolder treatment may be adopted.

Planting is another feature in relation to water which requires taste and skill on the part of the landscape gardener to ensure success. What an amount of colouring and variety of scenery can be obtained by the careful and tasteful distribution of trees or shrubs, whether singly or in masses. A sheet of water entirely shaded by trees would tend to render the water impure and stagnant, rob it of the glitter, the sparkle, the capacity for reflecting objects, which constitute some of the most agreeable attractions, while on the other hand a sheet of water without any planting would look crude, bare, and distasteful. It is then, as I said above, by the tasteful and appropriate planting of the margins of a lake that the many pleasing features of water can be effectively displayed.

Smoothness in the finish of the banks is essential, the turf being laid 6 to 8 inches below the margin, so that there may not be any hard line

of earth visible between the surface of the water and the grass. There is one exception to this rule, and that is where in secluded parts of the lake the banks are naturally precipitous, then great variety may be obtained by partially broken ground with Heather and rough grass, jutting rocks, old stumps of trees, and if there be a stream or brook running into the lake on that side, additional beauty and picturesqueness may be obtained by miniature waterfalls and cascades. This treatment, however, to be successful requires consummate taste and ingenuity.

(To be continued.)

LAPAGERIAS.

THERE can be no doubt that these plants will bear low temperatures without injury, and a slight frost reaching them when grown under glass does not appear to injure them in the least. But in houses where the winter temperature is low, and the house is also kept as cool and airy as possible in spring, the plants are placed at a great disadvantage in comparison with those that are accorded more genial treatment.

Under cool treatment throughout the year, or during the earlier months of the year, Lapagerias are naturally late in starting into growth, which largely influences the flowers they produce. The wood has no time to mature thoroughly, the flowers are late and do not possess that bright colour and size characteristic of good forms of *L. rosea*; while its companion, *L. alba*, is too often tinged with pink instead of being pure white. Late flowers of the last named, produced under cool autumn treatment, have in addition a greenish tinge that mars their beauty.

To grow Lapagerias freely, strongly, and rapidly, the structure in which they are accommodated should be kept close and moist from the present time, with a night temperature of about 50°. The conditions favourable for starting *Azaleas* and *Camellias* into growth after they have flowered are suitable for Lapagerias. They soon start into growth; in fact, if the temperature of the house in which they are growing has ranged from 40° to 45° throughout the winter, they will be ready for bursting at once into growth, and strong shoots will soon commence to issue from the base. By assisting them to make their growth early their shoots lengthen rapidly, and partially mature the foliage before the sun gains much power and shading becomes necessary. Cold draughts cause the young tender shoots to flag nearly as much as bright sunshine does, therefore little ventilation is given before April, when it may be gradually increased until greenhouse treatment is given them from the middle to the end of May. The plants have thus a longer season of growth and abundance of time to mature their wood thoroughly. This is important if they are to bear flowers freely, large and bright in colour, or of the purest white. Gentle warmth, even during the close of the flowering season, will prevent their coming green or tinged with pink. This is certainly the result of a low temperature. The plants increase much more rapidly in size by the gentle assistance advocated than they are capable of doing by the cool airy treatment too often given them.

Where Lapagerias can be planted out they make greater progress than in pots. This is not because they like a large amount of soil for their roots to ramble in, but because they are not exposed to the same drying influences as in pots. Their roots require a cool position where a uniform condition of moisture can be maintained without having to be continually pouring water into the soil. In selecting a place for them, hot-water pipes, or anything else that may tend to unduly dry the soil, should be avoided. Tubs decay, or they would be better than pots, because they do not dry, however rapid evaporation may be, quickly enough to be a source of danger to the roots. Probably the next best method is growing them in large pots, and plunging these to the rims to prevent evaporation.

The soil in which Lapagerias will flourish is not so important as many suppose, for I have seen them luxuriate in a variety of composts. A safe mixture, however, is good fibry loam and peat, broken up with the hand and used in equal proportions. To this add a liberal quantity of coarse sand, a few half-inch bones, a 7-inch potful to each barrowful of soil, as well as sandstone broken up. The latter we prefer, because the roots cling to it tenaciously, and it keeps the compost sweet and porous. Press the soil moderately firm, for the plants do better in it than when it is light and spongy, which necessitates frequent applications of water. When the plants are limited to pots a greater percentage of peat may be used, or all peat, which remains in a sweet condition for a longer period than a mixture of peat and loam.

Good drainage is absolutely necessary, but the border in which they are growing should not be over-drained. Although they like moisture in the soil about their roots they cannot endure it in a

stagnant condition. When the border is limited in size, and it is once well filled with roots, rich top-dressings are necessary. The surface should be annually removed down to the roots and good fibry loam supplied, with one-seventh of decayed manure, which will be found to assist them wonderfully.

The shoots are generally trained upright, especially strong suckers that issue from the base, and on the whole this is probably the best means of training them; in fact, strong shoots should be trained after this fashion the first season and allowed to extend as much as possible. Strong shoots from vigorous plants will travel yards in a season. If left in this position they will break freely, and make a spreading head towards the extremity. They may be allowed to do this with advantage. But when there is space to fill time is lost, and the progress of the plant sacrificed by allowing them to remain in this position after the second season. Few, if any of the lower eyes will burst into growth, they may remain dormant for years. Shoots of this nature, or old strong shoots that may have been trained upright, will produce a number of strong growths that will extend rapidly if they are laid horizontally at the base, and the weaker shoots at the top trained upright. Plants that are bare at the base will quickly be furnished with strong flowering wood by this simple process.

It is necessary to syringe the plants frequently to keep bare old stems practically moist for a time, until the buds swell and burst. A free use of the syringe is an advantage to the plants during the whole of the growing season, and should be discontinued only after the completion of growth until flowers are visible, when it may be continued until they show signs of expanding. If all the flowers are gathered a good syringing will prove beneficial. At the present time, on bright days, the syringe may be used twice daily, once will be ample on dull days. In May the syringe is used in the middle of the day as well as in the morning and afternoon. If young growths display signs of flagging during hot weather the syringe is used, and they soon revive. Little need be said about watering, suffice it that at no season of the year should the soil become dry. During the season of growth liberal supplies are needed. If once the border is full of roots weak stimulants may with advantage be given every alternate time they need water during the season of growth. Fresh cow manure placed in a tank with a bag of soot is a capital stimulant. It should be given in a clear state, or strained through fine tiffany and well diluted with water. At this season of the year the water needed at the roots and for syringing should be slightly warmer than the temperature of the house.

Pruning is rarely practised with these plants, although a little is requisite each season. This should consist of cutting back the shoots that have flowered to a good eye. It keeps the plants free from dead and dying shoots, which would be the case if that portion which flowers is not removed. This is all the pruning needed until the plants have filled the roof or the space allotted to them. It is a mistake, then, to allow puny growth to crowd the roof, and a judicious system of thinning should be practised. The shoots selected for removal must be cut back to a good eye, and by this method the space can be kept furnished with strong robust shoots that will flower freely and produce finer blooms than weak, short, stunted growths are capable of doing. If Lapagerias are thoroughly established they will bear more pruning than many suppose, and with advantage. Plants that make scarcely any growth annually generally flower profusely, too freely in fact, and they are much enfeebled. They may be restored to vigour by pruning. This is the only means of saving them, for if allowed to continue flowering they become weaker, and finally dwindle and die.

Nearly all the pests that infest plants will attack Lapagerias. Aphides are partial to them, but these are readily destroyed by fumigating with tobacco. Thrips are troublesome, but if the plants are freely syringed these will be kept in check. When established upon the plants fumigate with tobacco smoke two or three nights in succession, or thoroughly syringe with tobacco juice freely diluted with water, to which may be added half an ounce of soft soap to each gallon of water, and a piece of common washing soda the size of a cob nut. We prefer this to fumigating, only it renders the woodwork of the house unsightly. A solution of any of the insecticides recommended for the destruction of thrips may be used. It should be eradicated at once, for it quickly destroys the foliage and brings the growths of the plants to a standstill. If thrips appear when the foliage is firm and leathery a weak solution of petroleum and water, 2 ozs. to 3 gals. of water, will soon destroy it without injury to the plant. The same solution will destroy scale, from which the plants can soon be cleared if they are syringed two or three times in succession during the period of rest. Mealy bug is more difficult to deal with; it secretes itself behind the scales that protect the buds and cannot be reached with the syringe. Patience and perseverance in battling with it are the only means by which it can be exterminated.

Shade is necessary during bright sunshine. At first for a few hours daily, but during the months of June, July and August it is well to keep the blinds over the plants during the greater part of the day where they are grown in a structure facing south. As the growth matures it should be gradually discontinued, and dispensed with altogether by the end of September or early in the following month.

Where Lapagerias are grown for ornamental purposes, *L. maculata*, a pink variety beautifully marbled with white, should find a place. It is a strong grower with large bold foliage, and is sufficiently distinct from *L. rosea* to warrant me in saying it will become quite as popular. For market purposes the white form only is valuable.—WM. BARDNEY.

EVENTS OF THE WEEK.—On Saturday, March 22nd, a meeting of the British Fruit Growers' Association, in conjunction with the local Horticultural Society, will be held at the Town Hall, Ellesmere, Salop, at 7 P.M. The Royal Horticultural Society's Committees will meet in the Drill Hall, James Street, Westminster, on Tuesday, March 25th, at 12 noon, and the Royal Botanic Society's first spring Show of the season will take place on Wednesday, March 26th.

— **ROYAL HORTICULTURAL SOCIETY.**—At the last general meeting of the Society, Rev. W. Wilks, M.A., in the chair, the following were elected Fellows:—Thos. Barton, Rev. Thos. Bates, E. Bridges, M. Cammell, Thos. Christopher, Alister Clark, Esq., Mrs. John Clerk, J. Cobb, Geo. Colville, Jas. Crute, Hon. Hy. W. Fitzwilliam, Henry Fordham, C. W. B. Greaves, A. C. Harcourt, H. P. Harris, John Hart, S. Flower Jackson, Rev. A. Johnson, E. H. Jones, T. Wickham Jones, Jas. H. Laing, John A. Laing, F. F. Lambert, H. V. Machin, O. C. Marston, R. A. H. Mitchell, G. Munro, Mrs. Newton, Miss Nisbet, G. T. Partridge, H. G. Quilter, J. Roberts, Miss Frances Schreiber, Rev. John Sinclair, J. G. Smeaton, Edward Waltham, Mrs. H. Ward, F. Watson, Wm. Weale. Associate, W. G. Baker.

— **HALL FOR HORTICULTURE.**—At a meeting of the "Sites Committee," held on Monday last, it was resolved to call a great meeting, of which due notice will be given, of horticulturists and the horticultural trades throughout the kingdom, when the whole scheme and present position of affairs will be fully explained. The Committee hope that the trade, upon whose attitude much depends, will see that it is to their interest to popularise horticulture and take the matter up with spirit, and that a large number of gentlemen commercially interested in horticulture both in London and the provinces will attend, as the scheme will benefit the latter nearly if not quite as much as the former.

— **THE HORTICULTURAL CLUB.**—The usual monthly dinner and *conversazione* took place on Tuesday, March 11th. Dr. Hogg, in the absence of Mr. John Lee, presided, and there were present the Rev. W. Wilks, Rev. F. H. Gall, Messrs. T. W. Girdlestone, J. H. Veitch, A. Veitch, George Bunyard, H. J. Pearson, C. E. Pearson, T. Francis Rivers, C. T. Druery, &c. The subject for discussion, Plant Hybridism, was opened by a thoughtful and interesting paper by Mr. Lewis Castle, read in his unavoidable absence by Mr. George Bunyard. Mr. Veitch dealt with the subject in relation to Orchids, Mr. Druery to Ferns, Mr. C. Pearson to Pelargoniums, and Mr. Rivers to fruits, while most of the members present joined in the discussion, and a very interesting and profitable evening was spent.

— **NATIONAL ROSE SOCIETY.**—We understand that it has been determined by the Committee to alter the date of the annual dinner to June 24th, the day on which the exhibition of Tea Roses will be held at the Drill Hall. The dinner will take place at the Hotel Windsor at six o'clock, and the chair will be taken by the Very Rev. the Dean of Rochester.

— **THE DUTCH HORTICULTURAL SOCIETY.**—At the meeting of February 12th, 1890, Messrs. E. H. Krelage & Son at Haarlem sent a *Narcissus tazetta* called Grand Emperor, and a collection of bulbous and tuberous plants (vote of thanks). Honourable mention was

accorded to the same firm for a collection of cut flowers of different varieties of *Helleborus*, and for a *Helleborus Bocconi superbus*. *Iris Bornmulleri* from the same firm was awarded a second-class certificate. First-class certificates were awarded to Mr. R. Zaadnoordyk at Limmen for a new Tulip belonging to the group Duc Van Thol, and exhibited under the name of Cochenille Duc. This Tulip is distinguished by a dark red colour and extraordinary large flowers. A similar award was made to Messrs. Groenewegen & Co. at Amsterdam for an *Imantophyllum robustum elegans*, very robust in habit, and having large well-shaped dark coloured flower.—H. C. ZWART, *Secretary*.

— **THE WEATHER IN THE SOUTH OF ENGLAND** has been unusually fine during the past week. Bright sunny days, almost summer-like in temperature, have been the rule, followed by clear nights and slight morning frosts. Many plants and shrubs seem to have suffered severely by the recent sharp frost, Rose shoots especially being much cut.

— **THE WEATHER IN THE NORTH.**—March 10th to 17th. With the exception of 2° on the morning of the 14th there has been no frost during the week, dull and drizzly weather generally prevailing. At 9 P.M. on the 12th the thermometer stood at 50°. The 14th was fine and bright, and the morning of Sunday 16th was very mild and pleasant till mid-day, when it overcast and a good deal of thunder was heard in the distant S.E.—B. D.

— **GARDENERS' ORPHAN FUND.**—A number of growers of flowers for Covent Garden Market met the Committee of this Charity on Friday night last, and the meeting, under the presidency of Mr. G. Deal, unanimously accepted the Duke of Bedford's kind offer of the wholesale flower market for the purpose of a great Floral Fête on behalf of the Fund. It was decided to provide an unequalled display of plants and flowers on the evening of May 21st. The Lady Mayoress, accompanied by the Lord Mayor and city dignitaries, will attend for opening the Exhibition. Sixteen gentlemen, representing the growers and standholders of the market, were appointed to co-operate with the Committee of the Fund in making the necessary preparations for achieving what is hoped and expected will prove a brilliant success.

— **SPOT ON PELARGONIUMS.**—I had a number of plants spoiled by "spot" last season; they were healthy up till the time of potting, but after that they began to look bad, and had the appearance of having been sprinkled with hot water. I tried every means in my power, but to no purpose. I came to the conclusion that some old leaf mould which had been mixed with the potting compost was the cause of the mischief. When some of the plants were turned out I found many of the roots quite black and decaying; when the plants had been ripened I pruned them in hard, and when they had started to grow I shook them out and cut off all the discoloured roots, placing them in as small pots as possible, using a mixture of fibrous loam and sand only. They look well now, but are not quite clear; they have just been placed into their largest pots, the same compost being used as at the first potting, with the addition of half-inch bones. Should the spot again prove troublesome can any of your readers give me a remedy for it? The plants were most carefully watered; the fault is not in that direction.—C. RUSSELL, *Inquire*.

— In addition to the plants which have been named in recent issues of the Journal for covering the back walls of vineries, I might make mention of one which I have found a very effective covering, and exceedingly useful as well, that is *MYRSIPHYLLUM ASPARAGOIDES*. I planted it along the back wall of a vinery here last season, and trained it up by simply tying small strings to the bottom and top wires. The shoots soon took to these, and no more attention was required in the way of training. It is astonishing how closely the shoots keep twining themselves round the string, though resting against the intermediate wires. In no case did a shoot get behind a wire or twist itself round one, so that I cut any number of shoots up to 11 feet in length beautifully covered from top to bottom with its glossy foliage. The strings can be easily drawn out when the shoot is cut. These long sprays are simply invaluable in table decoration, as they can be twisted about in any form desired. I am just now preparing sufficient plants to do other five or six houses in the same way. The plant is easily raised from seed, and it is not yet too late to sow it. After it is established it keeps throwing up young shoots year after year. I cut twenty dozens of those long sprays during the Christmas week. Anyone who has much house and table decoration to do can easily understand what the value of those would be at such a time.—JOHN GARRETT, *Whittingham Gardens, Prestonkirk*.

— THE SCOTTISH PANSY SOCIETY'S SHOW is announced to be held in George Street, Edinburgh, on Friday, June 20th. The Secretary is Mr. McKennan, 144, Prince's Street.

— *The South Oxfordshire News* for March 15th contains a portrait of MR. JOHN WALKER OF THAME, with an account of his life and a description of his business. It is said that he commenced in 1846 with "20 poles of ground and a two-light frame."

— GARDENING APPOINTMENT.—Mr. Milner, for the last twelve years gardener at Sundorne Castle, succeeds Mr. Joseph Kinch as gardener to Miss Talbot, Penrice Castle, Swansea. Mr. Kinch went to Penrice from Margam recently and died suddenly. He leaves a widow and five children, one of whom we believe Mr. J. Muir contemplates nominating for election on the Gardeners' Orphan Fund.

— THE fourth Exhibition of the SCOTTISH PRIMULA AND AURICULA SOCIETY will be held in the City Assembly Rooms, Shore Terrace, Dundee, on Thursday, May 8th, 1890. Twenty-four classes are provided in the schedule, with prizes from 2s. to 20s. Mr. John Morris of Dundee offers 10s. "for the best named seedling (stage self) never before entered for competition." The Hon. Sec. and Treasurer is Mr. William Straton, Annfield Broughty Ferry.

— I READ with much interest Mr. Collier's article on the TUBEROUS BEGONIA, page 180, but I think he is a little behind the times when he says that Begonia seed sown in January will give us a few flowers the first year. Perhaps he would be interested to know that we have sown Begonia seed in February, and the plants have furnished 7 and 8-inch pots by the beginning of September and continued to flower until the middle of November.—G. W., *Henbury Hill*.

— CHRYSANTHEMUM MRS. CARTER.—We are pleased to find our illustration of this variety on page 445, November 1st, 1889, appreciated, and we recognise the fidelity of the reproduction of it as applied to Alice Carter and Mabel Carter in a catalogue of the firm by which the varieties were introduced, but we do not observe any mention of the original engraving in connection with the copies. This is the more noticeable since the source of another illustration of a variety that was not introduced by the firm is very properly recognised.

— NARCISSUS SPORTING.—Mr. James Walker of Whifton, Middlesex, who grows "millions of Daffodils" mainly for the London market, occasionally has sports among them. The last which he showed us was an example of two distinct varieties flowering from one bulb, namely, Sulphur Crown and Incomparabilis plenus, both forms being admirably represented. These varieties, also Orange Phoenix, Mr. Walker says, appear to be of the same origin, and flowers of any one of them may, and sometimes do, come from the same bulb.

— THE ORIGINAL HESSLE PEAR TREE.—I have received a letter from Mr. Lord of Hesse, in which he refers to a matter which may be of general interest, and I therefore send you the following extract. "It may probably interest you to know that the first or original Hesse Pear tree is still standing in my landlord's garden just behind my house. It is hollow and worn out with age, but still has a little life in it. Its age I cannot say for certain, but it has been stated to be considerably over 200 years, some say 300 years." Our florists' Tulips are looking well.—H. R. MEIN, *Kilso*.

— BRAMLEY'S SEEDLING APPLE.—I daresay many readers of the Journal will be inclined to think that the qualities of the above were overrated. I confess that until last September I was of that opinion. I then saw several trees in an orchard at Halloughton, near Southwell, that justified all that has been yet written in its favour, and I do not think it possible for anyone to overrate its qualities as I then saw it. I have at different times and in different parts of the country occasionally seen trees bearing splendid crops of Apples, but I have never seen such immense crops, and at the same time such fine fruits, upon the same trees. If it were possible for me to accurately describe those trees as I saw them people would not believe my statement, and I feel confident I should not have believed a similar statement regarding them.—J. U.

— CARNATIONS AND THE SPARROWS.—Many plants which have been out all the winter have been attacked by the sparrows, and the centre leaves, and in many instances the heart of the plant, has been eaten away. A friend who is a well known amateur grower of Carnations and Picotees, had recently a day's potting into the flowering pots, and the next morning he found that the birds had "pegged away" at his plants, and hard runing had resulted. He at once used lines of

black thread, not glazed thread, on the plants as they were potted from day to day, and thus secured them from injury. Many persons will see that their plants are mutilated, and wonder what is the reason; and Crocuses especially could be protected in this way.—DIANTHUS.

— FORCED IRISES.—Anyone having overgrown clumps of Iris germanica in their herbaceous and shrubby borders, and doubtless there are many such, may reduce them, and find them very useful for cut flowers. For the last few years I have found them force easily. This year some were taken from the borders the end of January, placed on the floor of vinery at work, with a little garden mould to cover the roots, and at the present time we are cutting the flowers. Some more crowns are also brought in now, and these will come on much more quickly than those dug up in January. If varieties are numerous a clump of each may be dug up at the same time; it will give a succession better, and when flowering is past the plants can be thrown on the rubbish heap unless wanted.—A HARDING, *Orton Hall Gardens, Peterborough*.

— BRUSSELS SPROUTS.—Your Leeds correspondent appears to have been fairly successful with this vegetable. I am expected to have Brussels Sprouts ready for the first dish of partridges in September, and my plan is to sow in August about the last day in that month out of doors. The plants remain in the seed bed till the first week in April, and are then planted 2 feet 6 inches each way. They are simply kept clean by having the hoe frequently run through the ground during the summer, and on the 1st of September we can always gather firm compact sprouts. The variety we grow is Sutton's Exhibition. Another sowing is made the first week in April. From these we commence gathering the first week in November, and continue until March, when they begin to open. Still they furnish Greens up to the end of April, thus giving eight months' supply. I am trying another plan for comparison, and will record the result in due time.—H. F. E., *Hampshire*.

— BLACKBERRIES.—A few weeks since fruiting Blackberries were a subject of remark in the Journal, and a copy of the number containing remarks by "Rubus" was sent to Mr. Laurence, at Harrisburg, U.S.A., and in a letter I have received from him he writes, "'Rubus' should see the American Blackberry grown the right way, and although you have some of the best American varieties in England they have not become popular. They need 6 feet apart between the rows, and 4 feet between the plants. The secret of fruiting is in pinching out the tops of the shoots when $3\frac{1}{2}$ or 4 feet high; then they throw out laterals, which should be pinched back to 10 or 12 inches, and good crops of fruit follow. They throw up canes like Raspberries, and the old ones are cleared out every year." As many persons planted these kinds I hope that some may be induced to give the Blackberries a further trial on the plan recommended above.—D. S. H.

— SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR FEBRUARY, 1890. — Mean temperature of month, 37.7°; maximum on the 1st, 50.3°; minimum on the 6th, 23.3°; maximum in the sun on the 27th, 94.9°; minimum on the grass on the 6th, 17.2°; mean temperature of the air at 9 A.M., 36.6°; mean temperature of the soil at 1 foot deep, 38.8°; nights below 32°, in shade 11°, on grass 18°. Total duration of sunshine forty-six hours, or 17 per cent. of possible duration. We had eleven sunless days. Total rainfall 0.99 inch; rain fell on twelve days. Average velocity of wind, 7.5 miles per hour; did not exceed 400 miles on any day, and fell short of 100 miles on six days. Approximate averages for February—mean temperature, 40.2°; sunshine, fifty-six hours; rainfall, 1.63 inch. A cold dry month, only one really wet day. The temperature is over 4° lower than in January. We have now had cold and dry months of February for five consecutive years.—JOSEPH MALLENDER.

— AN EARLY HORSE CHESTNUT.—The Paris correspondent of a London daily paper says, "The famous Horse Chestnut tree in the Garden of the Tuileries, which is known far and wide as Le Marronnier du Vingt Mars, because, as tradition has it, its branches are always bedecked with tender leaves by that date, is acting its part to perfection this season. It must be confessed that this celebrated tree—which, at the approach of spring, is attentively scrutinised by numbers of eager Parisians on the look-out for some sign of verdure—now and then disappoints its admirers by failing to 'come up to time.' This year, however, in spite of the intense cold which prevailed at the beginning of the month, it is well to the fore, being covered with buds which are bursting and shooting in every direction. It has still four days for the completion of its toilette, and naturally the omen is regarded as propitious, for not long

ago there was considerable misgiving on this subject, it being apprehended that the fine old tree, the name of which is a household word in this metropolis, might be hadly beaten by the 'enemy.' The weather, indeed, is extremely favourable to the development of leaves and buds, and already the Marronnier has not a few competitors which are running it rather close. A mild temperature with bright sunshine or light showers has worked wonders during the past few days."

— A LECTURE ON "APPLES: THEIR CULTURE AND USES," was given by W. Roupell, Esq., at the British Workmen's Club, Upper Tulse Hill, to a large and appreciative audience on Friday, the 14th instant, for the benefit of the Gardeners' Orphan Fund. The Chairman, Buxton Morrish, Esq., after giving an account of the origin of the Fund, made a powerful appeal to those present to support so admirable an institution. Mr. Roupell then proceeded with his lecture, giving some practical details for the management of the trees, such as planting, pruning, cleansing, and renovating old worn-out trees, &c.; also the different uses to which Apples had and might be put. The lecturer, who had in front of him a collection of well preserved fruits, gave a list of suitable varieties to cultivate. During the lecture Mr. Roupell referred to the good that was likely to result from the establishment of the British Fruit Growers' Association, and spoke of the appeals already made to that body for help in isolated districts. The frequent and hearty applause testified to the esteem in which Mr. Roupell is held in his own neighbourhood.—E. B.

— THE fortnightly meeting of the READING GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION was held on Monday evening last. There was, as usual, a large attendance of members. R. D. Catchpool, Esq., occupied the chair. Mr. Richard Dean of Ealing read an interesting paper, entitled "The Wonderful in Horticulture." Some magnificent Orchids were exhibited by Mr. Pound, gardener to G. May, Esq., of Caversham, and were remarkable for their fine health and vigour. The most noticeable were *Phalenopsis Schilleriana*, carrying upwards of thirty fully developed flowers; *P. Stuartiana*, equally well flowered; a fine specimen of *Dendrobium nobile*, *Goodyera discolor*, and *Odontoglossum pulchellum*, all profusely flowered specimens. A fine plant of *Dendrobium Wardianum* was exhibited by Mr. Woolford, gardener to A. Palmer, Esq. The Secretary announced that he had received from Mr. B. S. Williams some valuable books as a donation to the library.

— IMPORTANT TO NURSERYMEN.—The following report has been sent to us for publication:—An action was heard at the Westminster County Court on the 12th inst., which was brought by M. August Van Geert of Ghent against Messrs. James Carter & Co. of High Holborn to recover the price of some Camellias supplied in the autumn of last year, and which reached Messrs. Carter & Co. in an unsalvageable condition, the leaves and buds having fallen from the plants; and as M. Van Geert would neither make any allowance nor replace the plants, Messrs. Carter & Co. were compelled on principle to defend the action. The defence involved the important question as to who was responsible for the damage, as the plants were sent to the agents of M. Van Geert in the city, and the defendants had no knowledge of the carriers or the route by which they were sent from Ghent, although they appear to have paid the freight to the carriers in a lump sum with the charge for bringing the plants from M. Van Geert's agent to Messrs. Carter's warehouse in High Holborn, and upon this fact coupled with the statement in a printed catalogue of M. Van Geert's that "all plants travel at expense and risk of purchasers," it was decided by His Honour Judge Bayley that the defendants were liable. In the case of another consignment which Messrs. Carter received from M. Van Houtte about the same time in a damaged condition it was unnecessary to bring the matter into a County Court, as M. Van. Houtte very promptly and liberally met Messrs. Carter in the matter by sending other plants to replace those which had been injured.

— HANGING BASKETS FOR GREENHOUSES.—In places where large and lofty structures are used for the flowering of greenhouse plants, the beauty of the display is greatly enhanced by baskets suspended from the roof. The baskets may be made either of wood or wire, the former, I think, from their more rustic appearance, looking better. They are usually made square. The pieces of wood which form them must be made equal length, and holes drilled through them about an inch from the ends. Four lengths of copper wire are required, one for each corner. The wire should be put through each piece of wood and brought up to form a handle for suspending from the roofing. A great many plants are well adapted to basket culture, and if the colours are tastefully

blended the effect is very pleasing. Tuberous Begonias, either single or double, are excellent for this work, a good plant being placed in the centre with an edging of any drooping plant, such as Musk, seedling Lohelia (white or blue), *Sibthorpia*, *Panicum*, &c. Small specimen Fuchsias do well with similar edging, while baskets of Ivy-leaved Pelargoniums, *Tradescantia*, *Fittonia*, or *Achimenes* are also very beautiful. Some of the greenhouse Ferns thrive well in baskets, particularly those with creeping rhizomes like the genus *Davallia*, which grow over and in time completely hide the basket if left undisturbed. If they are well attended to with water during the growing season it will be found that a great number of plants do as well in this position as in any other, and when any of the flowering plants fade they can easily be replaced with fresh ones. It would be well when hanging them to notice that the superfluous water will fall on the floor, and not on plants growing beneath, which might be injured in consequence.—O. C.

— POPULAR ROSES IN AMERICA.—At the February meeting of the Pennsylvania Horticultural Society, held in Philadelphia, an attempt was made to test the relative popularity of the Hybrid Perpetual Roses *Madame Gabriel Luizet* and *Mrs. John Laing*; the choice was made by ballot, and resulted in a majority of twenty-seven votes in favour of *Madame Gabriel Luizet* in a total vote of about ninety. A similar contest between *La France* and the *Duchess of Albany* resulted in a majority for the first-named. It would seem that these two varieties (*Madame Gabriel Luizet* and *La France*) are securely fixed in the affections of the Philadelphia horticulturists, and may not easily be displaced by the newer varieties, even though these are Roses of the very first rank.

— ORANGE CULTURE AT JAFFA, according to Consul Gilman, has become an industry of great value. Of the 9000 acres of cultivated land pertaining to the community, 3000 acres are covered by Orange groves and gardens; and these are all under irrigation. Among the other fruits produced are the Lemon, Lime, Citron, Date, Peach, Apricot, Grape, Fig, Pomegranate, Plum, and Melon, as well as the Olive. All the ordinary garden vegetables are also grown here of good quality and in abundance. Of late, the Vine especially is receiving increased attention and care; extensive vineyards are being planted; and as here the Vine is free from the diseases and insect pests of other countries, and the soil and climate are peculiarly adapted to it, this should be one of the most flourishing wine-producing countries in the world. The Olive does best in the hill country, and generously responds with abundant crops to the slightest care.—(*American Garden*.)

DESTROYING CATERPILLARS.

IN your issue of March 5th I find a report of a conference of fruit growers held at Evesham to consider the best means to destroy the green caterpillar on fruit bushes and trees. As they seem to be quite at a loss how to proceed to the destruction of them I beg to say that I have for several years made a mixture which entirely destroys them, and as a proof of it I enclose copies of two certificates which I received some years ago, and which I think will prove more than I can say about it. Further than that, it is non-poisonous, as any fruit may be taken from the tree and used at once. This was the only difficulty to contend with. The growth of the tree is much improved by the use of it, and being dissolved in water only requires the use of a syringe.

By inserting this in your next issue I shall feel obliged.—EDWD. CRUMMOCK.

[The testimonials received are satisfactory, and if the preparation is made for sale it should be kept before the public in the usual business way—advertising.]

CULTURE OF THE EGG PLANT.

ALTHOUGH the Egg Plant is not of such general use in English kitchens as it is in that of the southern countries, still it may interest some of your readers to know how we grow it under the climate of Paris. The Early Long Purple is almost the only sort which we can grow here. Most of the other varieties, being much later, are not suited for Paris or for England. The Early Dwarf Purple, which is a month earlier than the other kinds known in France, may be grown too, particularly in hothouses, on account of its compact habit, but the fruits are rather small and do not exceed the size of a medium Pear.

We sow the seed in March on a hotbed, prick out the seedlings into another hotbed, with a temperature of from 70° to 75° Fahr., and when the plants are strong enough towards May take them to their permanent quarters. We usually plant two rows of Egg Plants in a Melon frame measuring about 4 feet 4 inches each side, so that when the Melons are lifted the Egg Plants take their places, and stand about 18 inches apart in the rows, the latter being 24 inches apart; they thus have plenty of room and air, and yield fine fruits.

They can also be grown on a gentle hotbed under glass towards the

middle of May at a distance of about 20 inches, on substantial soil, the frame being in that case taken off in June. They may besides be grown on a warm house border, with bottom heat, but plenty of ventilation must be given. They may be also grown in a hothouse in pots which

quarters their full size, and according to the season fetch from 2d. to 4d. each in our market. During the setting of the fruits some care and attention should be given, and the extremities of the growth pinched. We use tobacco juice against insect pests.—E. SCHAEFFEL, *Paris*.

FIG. 32.—ARISÆMA SPECIOSUM.

are plunged on a warm bed covered with some earth, in order that the pots do not rest on the dung.

The plants require plentiful waterings during summer, and the more light, heat, and sun they have the better the fruit. We usually leave but three branches on each plant, which may yield from five to eight fruits. The latter, for culinary purposes, should be gathered when about three-

ARISÆMA SPECIOSUM.

AMONGST the Arisæmas we have some of the most ornamental Aroids if the brilliant Anthuriums and the invaluable Richardia be excepted. One of the most showy of these—*Arisæma speciosum*—was exhibited from the Royal Gardens, Kew, at the meeting of the Royal

Horticultural Society on March 11th last, and is depicted in the illustration (fig. 32). The leaves are trifoliate, rather graceful in appearance, but the spathe is boldly marked, being of a deep purplish maroon colour slightly tinged with brown, clearly and distinctly streaked from base to apex with white. The plant is a native of the Temperate Himalayas, and was introduced in 1872.

Most of the *Arisæmas* succeed in an intermediate temperature, but some require a stove, and others, again, will thrive in a greenhouse; all, however, need an open soil and abundance of water during growth, shallow pots or pans suiting them, as they do not seem to require much depth of soil.

ROYAL HORTICULTURAL SOCIETY.

MARCH 11TH.

SCIENTIFIC COMMITTEE.—Professor Church in the chair. Present:—Messrs. Blandford, Wilks, Morris, Drs. Hugo Müller, Frank Oliver, Scott, Masters, and Professor Marshall Ward.

Effects of London Fogs on Plants.—Mr. Morris read the terms of an application for a sum of money from the Government grant administered by the Royal Society, to be devoted to the partial payment of the expenses connected with the inquiry into the composition of London fog, with special reference to those of its constituents that are injurious to plants.

Fruit of Loranthus.—Mr. Morris stated, on the authority of Professor Oliver, that the fruit of the *Loranthus* attached to the panicle of the Sugar-cane, as exhibited at a previous meeting, was *L. americanus*.

Sugar-cane Borer.—Mr. Blandford reported that the moth mentioned at the last meeting as injuring Sugar-canes in St. Vincent was *Diatrea saccharalis*. The beetle alluded to on the same occasion is known as *Xyleborus perforans*, and was originally described by Wollaston in his "Catalogue of the Coleoptera of Madeira," page 96. It occasions great injury to the bungs of the wine casks in Madeira. Wollaston found it commonly feeding in the stems of *Jatropha curcas*.

Seedlings of Sugar-cane.—Mr. Morris, in continuation of information placed before the Committee on December 10th, exhibited specimens of mature seeds of the common Sugar-cane (*Saccharum officinarum*). There were also shown germinating seeds, some plants, drawings of the flower, and dissections of the fruit (caryopsis) in detail. Mr. Morris stated that there appeared to be no authentic record of any really wild station for the Sugar-cane; further, that the fruit of the Sugar-cane had not hitherto been figured or described. At Barbadoes several times during the last twenty years, and more recently by Professor Harrison and Mr. Bouch, self-sown seedlings of the Sugar-cane had been observed. The subject was taken up systematically in 1888, and about sixty of the seedlings had been raised to mature canes. Many of these exhibited well-marked characteristics, differing from the varieties growing near them. Careful inquiry had shown that canes known as the "Purple Transparent" and "White Transparent," and possibly also the "Bourbon" cane, produced seeds in very moderate quantities. Spikelets received at Kew had been examined and the seed found *in situ*. A description with figures had recently been laid before the Linnæan Society by Mr. Morris. It is anticipated that by cross-fertilisation and a careful selection of seedlings, it will now be possible to raise new and improved varieties of Sugar-cane, and renew the constitutional vigour of plants that have become deteriorated through continuous cultivation by cuttings or slips. Great importance is attached to the subject in sugar-producing countries, as it opens up an entirely new field of investigation in regard to Sugar-cane cultivation.

SPARMANNIA AFRICANA.

THIS fine Cape plant, which has been in our gardens now for something like a century, deserves more attention than is generally paid to it, which but too often consists in just keeping alive one or two old semi-nude plants in any convenient corner of the greenhouse or some other such structure.

In May and June the *Sparmannia* is usually crowned with its numerous umbels of snow white flowers, containing as they do a multitude of gaudy stamens—which reminds us forcibly of the popular *Hypericum* of our borders associated with a beautifully white corolla, instead of its familiar guardian in gold. It possesses, however, qualities of far more importance to the gardener than those we have just named. When a young stock is kept up—and it is easily propagated—it furnishes material for the cut flower basket through the greater portion of the year. Its double form, *S. africana* var. *flore pleno*, is the best for this purpose, which, though destitute of the beautiful stamens of the old favourite, amply compensates with an abundance of petals veined with deep rose. The flowers of the variety are slightly larger than those of the species, from which they vary in another respect—viz., their somewhat pendulous habit. I cannot conceive of a more profitable cool-house plant where cut flowers are in demand.

From what we gleaned in a recent visit to Messrs. B. S. Williams and Son's nurseries, Upper Holloway, it appears that gardeners are now becoming alive to this fact, the demand being on a steady increase. *Sparmannias* are easily struck where young shoots are to be obtained, giving no more trouble than the ordinary tenants of the propagating house. Our own practice is to place one or two old

plants, well spurred back, into an early vinery, where, by the middle of April, they produce plenty of young growth suitable for cuttings, which we insert rather thickly, to economise space, in 48-sized pots, and plunge in the bed of the propagating house. Bottom heat is not absolutely necessary for them, but they root all the quicker for it. When rooted, they are potted singly in 60's in a compost of loam and leaf mould, with a dash of coarse silver sand to keep the whole porous. They are again shifted when necessary into various sizes as required, using the same compost.

The *Sparmannia* is by no means a gross feeder, all it requires being plenty of light and well drained, wholesome soil. Old plants should in every instance be well shaken out of the old compost before being placed in new quarters, which should be as confined as possible, shifting into large sizes as required, rather than overpotting in the first instance. Plants thus treated will retain their foliage better than when treated in a careless manner.—W. R. W.

A NOTED BOTANIST.

DR. C. C. PARRY died at his home in Davenport, Iowa, on the 20th of last month, from pneumonia, which followed an attack of influenza, contracted in the east. He paid a long visit to botanical friends in the autumn and early winter, and while here was busy investigating various matters connected with the California flora. He was then in perfect health apparently, active and alert in mind and body, and full of plans for new work. He was enthusiastic in discussing new expeditions in the far west, and full of reminiscences of travel and adventure. Though sixty-six years of age, we little thought then that our friend's wanderings were so near an end.

Charles C. Parry was born in Admington, England, on August 28th, 1823. His family emigrated to America nine years later, and settled on a farm in Washington County, New York. Dr. Parry was educated at Union College, and then studied medicine. He was interested, however, in botany even at this period of his life, and although he practised his profession for a short time in Davenport, where his family removed in 1846, he soon abandoned it for the more congenial pursuit of natural history. He had devoted much attention to collecting the plants of New York before he moved to Iowa, and these studies secured for him the acquaintance of Dr. John Torrey and Dr. Asa Gray. Their acquaintance confirmed his taste for botanical exploration, and exerted a powerful influence upon the remainder of his life.

Dr. Parry's real work as an explorer began in 1849, when he was attached to David Dale Owen's survey of Wisconsin, and made a collection of plants in the valleys of the St. Croix and St. Peter Rivers. The next year he joined the botanical staff of the Mexican Boundary Survey, and crossed the California desert from San Diego to the mouth of the Gila River. This journey and the subsequent ones which he made as a member of the survey, and which extended through two or three years, and carried him overland from the Pacific Ocean to the Gulf of Mexico, were rich in botanical discoveries of the most interesting character. These are found recorded in the "Report of the Mexican Boundary Survey," published in 1852. Persons who cross these deserts now in Pullman palace cars can form a very slight idea of the sufferings and hardships of these early explorers, who passed months in travelling distances now covered in as many days.

Dr. Parry's next conspicuous service to American botany was performed in 1861, when he began his examination of the flora of the central Rocky Mountains. This work, undertaken mainly at his own expense, occupied him several years. The Colorado Mountains were at that time a fresh field practically, their flora being known only by the scant material brought back many years before by the naturalist of Major Long's expedition, and Dr. Parry was able to reap a rich harvest from the plants which extend to the summits of the alpine peaks, which he was the first botanist to reach. He made, too, at this time valuable meteorological and topographical observations, afterward elaborated by Dr. Engelmann. Dr. Parry was appointed in 1869 as botanist of the Agricultural Department at Washington, and occupied this position for two years. He was, however, an explorer by temperament and by habit, and he had little liking for the restraints of an office position. This taste for travel he was able to gratify for the last twenty years, during which he was more or less continuously in the field, either in Nevada and Utah, where he made many discoveries, or in Mexico and California, where much of the last part of his life was passed. He always kept his home, however, at Davenport, in whose Academy of Natural Sciences he was deeply interested. This he made several years ago the depository of his herbarium, which was of course exceedingly rich in western plants, and which, besides his own collections, contained those of many correspondents.

Dr. Parry discovered hundreds of new plants afterwards described by Dr. Gray and by Dr. Engelmann, and his name is so firmly fixed in this way in the history of American botany that, although he published very little, it will be remembered as long as the plants of western America continue to interest the students of botany. Horticulturists will not forget that it was Dr. Parry who discovered *Picea pungens*, the beautiful Blue Spruce of our gardens; *Pinus Engelmanni*, *P. Torreyana*, *P. Parryana*, and *P. aristata*; nor that it was through his zeal and enterprise that many plants now familiar to us were first cultivated. With Dr. Parry there passes away the last, with a single exception, of the remarkable group of men who became prominent as botanical explorers soon after the great addition to the territory of the United

States which followed the close of the Mexican war, and who, fired by the enthusiasm of Asa Gray, opened to the world under his guidance the botanical treasures of the western and south-western parts of this country.—(*American Garden and Forest*, March 5th.)

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY (Continued from page 225.)

A SLIGHT accident in the type in making up the article last week, necessitates the reproduction of a few lines to render the references to Gloire de Dijon intelligible.

Gloire de Dijon.—A Rose of such notoriety, which forms seed vessels freely, has naturally been a prolific parent of Roses of similar manners and customs, forming a race to themselves. Perhaps the best of these are Bouquet d'Or (Ducher, 1872)—which, strange to say, is classed among the Noisettes in all the catalogues which I have seen except those of the National Rose Society and of Mr. G. Paul—Belle Lyonnaise (Levet, 1869), which is sometimes considered good enough to show, and Madame Berard (Levet, 1870), a better shaped Rose, but quite a shy bloomer with me. There are many others, and the cry is still they come. A large variety in colour has been obtained, but all seem to be much inferior to the original in its strongest point—constant freedom of bloom.

Homer (Robert, 1859).—Of very strong growth with fair foliage, but more suited for a pillar than a wall, and best as a big bush. I have never heard any doubts about this being a pure Tea, but it is of unique habit and manners, being, as far as I have seen, perfectly hardy and of strong constitution, and I wonder we have had no seedlings from it. It is not liable to mildew and but little injured by rain, does well as a dwarf, is a free bloomer and fair autumnal, pretty in colour, but small in size. It is hard to prove a negative, and I will not say that Homer never comes perfectly shaped, because I have heard of one, though I did not see it. Its bad manners in this respect are more aggravating because each imperfect bloom has the promise of a beautiful shape, but marred by a malformation. As often happens, the strongest blooms are the most imperfect, and the buds should be cut small, as buds, before their promise is spoiled. The exhibitor will have none of it, but for buttonholes and bouquets he cannot deny the buds the despised epithet of "pretty." Nay, I saw lately in the inquiry column of a horticultural paper a note from a correspondent asking for names of "three of the the most sure, certain, and useful blooming Roses," and he was referred by the Editor to *Gloire de Dijon*, *Souvenir de la Malmaison*, and *Homer*! Well, well! tastes vary, and no doubt it is right they should, else all the young men in the world would be in love with the same young lady, and (which is more to our present purpose, though perhaps less disastrous) there would be an end to all those pleasing varieties of opinion as to which are the best Roses (and even as to which are Tea Roses) which have made the statistical returns of the Rose Conference so interesting to Rose lovers.

Hon. Edith Gifford (Guillot, 1882).—Of small growth and foliage, rather liable to mildew, but much injured by rain. A very good Tea Rose indeed, the blooms of which come very well, of fine shape, petal, centre, and size. It is thoroughly reliable, an excellent show Rose, early, free blooming, a good autumnal, and does well as a dwarf. A good Rose and a good "doer," a great acquisition, and a large improvement upon *Devoniensis*. I see that one catalogue at least has managed to describe its colour at some length without using the objectionable (?) word "white," and I am sure all who know the Rose will appreciate the feat.

Innocente Pirola (Ducher, 1878).—Of only fair growth and foliage; requires rich soil, and does not do so well as a dwarf; not much liable to mildew nor absolutely spoiled by a little rain. The blooms come well, and the shape is one of the most perfect we have, like the whorl of a shell. It is fairly free in bloom and lasting, but not one of the best autumnals, and not often very large till overblown. Most pure in colour, but, dear me! three of the leading catalogues describe its colour without mentioning the word "white!" I can only suppose there is some mysterious point of honour about it. Fine in petal and centre. This Rose should be a great favourite with those purists (with whom I have much sympathy), who insist upon regularity and perfection of shape as being the one thing desirable above all others.

Jean Ducher (Ducher, 1874).—Of strong, stout, stiff growth, with good foliage; does well as a dwarf, and is not very liable to mildew, but perhaps more sensitive than any Tea Rose to wet or rain. It must have dry weather, even when yet a hard bud, as soon as ever it shows colour, or it will not come to any real good. The very strongest buds are apt to come rough or divided, but as a rule they come pretty well if the weather continues dry, and when a fine bloom does come at last it is grand in shape, petal, centre, size, colour, and lasting qualities. It is a thoroughly free bloomer, good in a dry autumn, and fairly hardy for a Tea Rose. The colour is variable; sometimes there is a good deal of salmon pink about it, especially on the outside; rarely it is quite yellow,

and then very fine; when overblown the blooms have a good deal of red in them, and are very decorative at a little distance.

Jules Finger (Ducher, 1879).—Of good growth, with fair foliage; does well as a dwarf, is not much liable to mildew, and can stand a shower. The blooms generally come well, but the shape is not a refined one, the centre petals being incurved, whereas we expect the more elegant pointed form in a Tea Rose. Pretty good as a free bloomer and autumnal, not very large, and aggravating in colour. This is fairly good and pure when the flower first opens, but it will not hold it when cut, and if kept too long (for it has a lasting shape) it turns to a livid hue, which almost tempts one to use the word "ugly." Note that there is a *Julius Finger* among the H.P.'s, a light coloured flower of little merit.

La Boule d'Or (Margottin, 1860).—Of fair, stiff, but rather dwarf growth, with good foliage; very little liable to mildew, but being extra full it is a slow opener, and will not stand any wet. It does well as a dwarf, and the blooms come fairly well, though occasionally divided. This is a Rose of very large fine petals, which give it great value for show purposes, but it has rather a bad name as one that will not open. I have even heard it recommended that the roots should be cut in summer when the buds are formed to starve it into opening; but I cannot advise root-pruning for any Rose, except perhaps *Climbing Devoniensis*. It is a grand flower under glass, and well worthy of some artificial protection from rain when grown out of doors for exhibition; but this is not an easy business to manage satisfactorily. I have experimented with several sorts of caps, shades, and cones, but hope there is something better, firmer, cheaper, and more easily shifted yet to be found. Whatever be used let no one make the mistake of replacing the cover when the ground is wet, or the radiating moisture will settle on and rot the petals. It is seldom of any use as an autumnal, but is free blooming, capable of reaching a large size, and of extraordinary lasting qualities. I have seen a strong bloom on a south wall, exposed to a cloudless July sun, take nearly a week to open fully. The typical shape, as the name implies, has a round ball in the centre, but it often comes with a fine point, and is then much better, the great petals standing out like wings. "Bright golden yellow" is the general description of the colour, but this shade is unattainable out of doors, as it will not open without sun, which makes the colour much paler. After cold wet weather the buds (if any survive) will open much more quickly should a sunny time follow.

Madame Angèle Jacquier (Guillot, 1879).—Of pretty good growth and foliage, not much liable to mildew, but injured by rain. It will do well as a dwarf, but wants rich soil and high culture to be worth anything. The blooms come generally pretty well, and a good show flower may often be obtained, of fine petals, nice pointed shape, and full size. The colour is not striking, and, however described, it will be found more white than any other colour when grown out of doors. This is a Rose which seems to have improved or grown in favour during the last two or three years, but it is not specially noticeable as a free bloomer or autumnal.

Madame Berard (Levet, 1870).—See *Gloire de Dijon*.

Madame Bravy (Guillot, 1848).—Synonyms: *Alba Rosea*, *Josephine Malton*, and *Madame de Sertot*. Of good growth and fair foliage, not liable to mildew, but impatient of rain, and rarely producing show blooms when grown as a dwarf. The blooms come generally well, but the shape is very globular, almost like an incurved *Chrysanthemum*, and such a form requires the utmost regularity, and shows at a glance the slightest imperfection. The wood is pliable, and the blooms are therefore pendant, and can only be seen in perfection when artificially supported in a vase or Rose stand. A very free bloomer and fairly hardy, but the autumnal buds rarely expand fully. It is of fair size, but owing to the globular shape loses in this respect when compared with other Roses whose outer petals are long and stand well away, and is seldom large enough to be shown among H.P.'s. I do not know whether this Rose has deteriorated of late, but one does not, I fancy, see it shown so often as formerly. The objection of some Tea Roses to be grown as dwarfs, a mode of culture which affords the greatest facilities for protection from frost, seems likely to cause such dainty varieties to lose in popularity.

Madame Cusin (Guillot, 1881).—Of poor growth, with characteristic wood and very small foliage; not much injured by rain, but liable to mildew, and I cannot get it to do any good as a dwarf—indeed, few seem to be able to grow this Rose strongly, and it is not often seen well shown. The blooms almost always come well, and the shape is unique, with a fine point in the centre, and the petals all well separated and standing apart from one another. No dressing is required for this Rose, as the spreading out of the petals is one of the chief objects of this practice. Not large, but very free flowering; the buds must be rigorously thinned and the plant treated most generously if anything much above buttonhole size be aimed at. A fine colour sometimes, but this, as is often the case, is fleeting, and the general hue soon becomes dull.

Madame de Watterville (Guillot, 1883).—This Rose, which formed a new and notable departure in Tea Roses, seems to me slightly similar in strain to the last-named. The growth is never more than moderate with me; the foliage is small, and I cannot make it do well as a dwarf. For the first two or three years of its existence it was, I think, only shown in its full beauty by one rosarian, but all the leading exhibitors are able to grow wonderful blooms of it now. I suppose it is done from standards. The blooms come well, even though the buds be crinkled and apparently badly shaped, and the appearance of the flower is

unique and charming, with great wing-like petals, which give it a most effective appearance. It is sometimes "altered in character," I should say, by dressing, but it would be difficult to make it look anything but lovely. Liable to mildew, but not absolutely intolerant of rain; a very free bloomer of most charming huds, but these must be unsparingly thinned to see the Rose in perfection. It is of large size if grown as it should be, able to hold its own with any H.P.'s, and excellent in every good quality. I do not find it to be of good constitution or long-lived as a plant, and should not call it a good autumnal.—W. R. RAILLEM.

(To be continued.)

MARÉCHAL NIEL ROSE.

THE following may perhaps interest some of your readers. Last April I moved two plants of this Rose out of 6-inch into 12-inch pots, using rather heavy fibrous loam only. They were placed in a late Peach house and trained to the roof, fully exposed to the sun. They grew rapidly, and at the end of the season one plant, confined to one shoot, measured 21 feet of young growth. The other plant had three growths, which measured collectively 23 feet. They were turned outside at the end of September to ripen their wood. The plant with the single shoot has forty flower buds on it now, the other plant thirty. The former is coiled round four stakes placed in the pot. I may mention that the plants had an occasional surface sprinkling of Beeson's manure during their growing season. They are on their own roots, having been struck in the summer of 1888.—C. RUSSELL.

MIGNONETTE IN WINTER AND SPRING.

I NOTICED recently some fine specimen plants of Mignonette in the gardens of E. R. Trotman, Esq., The Elms, Frome. The seeds, I am told, were sown several in a 48-sized pot, and the seedlings were reduced to four in each pot when sufficiently advanced in growth. From these pots they were removed into others 10 inches in diameter, which seems rather a large shift, but their present condition speaks volumes in favour of the liberal treatment. They are 2 feet high and proportionately hushy and crowned with vigorous flower spikes in goodly numbers. The soil used consisted of loam three parts to one each of spent Mushroom bed, leaf mould and sand. In potting the soil was pressed down firmly, which induced a sturdy growth, and until recently no stimulant was applied of any kind. They occupied a position in the front of a large and lofty vinery having deep front lights, and only a frost-proof temperature was maintained.

BEGONIAS.

On entering a small stove in the same garden I was much struck with the beauty of some Begonias of the variety Gloire de Sceaux, having bold spikes of large and beautiful pink-coloured flowers. The latter is well displayed from their upright character of growth, and is well relieved by its dark bronzy foliage. It is a continuous flowering plant of the evergreen fibrous-rooted section, and makes in a small state remarkably effective table plants for the house. It requires intermediate or stove temperature in winter, but, like *B. nitida*, may be used for conservatory decoration in summer. It is a plant of somewhat recent introduction, sent out, I believe, by Mr. William Bull of Chelsea, and those unpossessed of, or having a liking for these plants, should certainly not be without this, one of the most beautiful of the Begonia family. It merits a place in every collection, even for the beauty of the foliage alone, which is of very fine lustre when grown in a light position.—W. S., Frome.

CANNAS.

STATELY in growth, with highly ornamental leaves and attractive flowers, Cannas are altogether noble and effective for decorative purposes, the chief purpose to which they are applied being sub-tropical or summer gardening. They are also extremely useful for decoration in the conservatory and house. No plants are more easily grown. They are also readily increased by seed.

The seeds should be sown in heat in March. I usually sow them in a Cucumber pit. They may be soaked for twenty-four hours in tepid water, which will materially stimulate germination, the seeds being very hard. Old seeds are long in germinating and uncertain. They may be sown thinly in pans, the seeds being placed about an inch apart in a compost of equal parts of light fibrous loam, leaf soil, and sand, covered to the depth of about an inch. Care is taken to keep the soil uniformly moist. When the plants appear they are well exposed to light, and a sharp look out is kept for slugs and even crickets, which are fond of the young growths. Searching with a lantern is best for the former, and phosphor paste (an old remedy) makes quick work of the crickets, also of blackbeetles or cockroaches. These are creatures that often clear off a pan of seedlings as they appear, and the seedsman is blamed. When the seedlings have formed two leaves I lift them carefully with the end of a label, and pot them singly in 3-inch pots. The soil used is equal parts loam, manure, sand, and a dash of Thomson's manure, a little peat being a beneficial addition. The soil can hardly be too rich and porous. As the seedlings become large enough they are transferred to pots. Keep the plants growing in a temperature of 60° to 65°, with an advance of 10° to 15° or more by day, and instead of allowing them to become stunted in the small pots they may be given a size larger, or 5 to 6-inch pots when they have filled

the first, or 3-inch pots, with roots. Towards the close of May they should be hardened in a greenhouse or in any structure where they can be kept rather close for a few days, and then prepared for planting out early in June.

Propagation is also effected very readily by means of division. The Cannas form rootstocks, not unlike a German Iris, and these may be broken or cut up in spring, being careful to retain a bud and portion of roots to each division. Place them singly in 4-inch pots, or such a size as will hold the root divisions with an addition of soil all around. Placed in a house with a temperature of 60° to 65° they will start freely, but are the better for a bottom heat of 75°, in which they quickly root and grow freely. They do very well in a vinery or other forcing house, but they always do best when grown on in plenty of light and in a position well up to the glass. They should be transferred to larger pots as they require it, and they will be useful by the early part of June for planting out, care being taken to harden them previously.

In some instances the pot system is dispensed with. If stored in boxes or in any safe place for the winter in sand the rootstocks are divided and placed in boxes in spring, and are given such positions in houses at command as will insure their gentle advance until the time arrives for planting out, the plants being transferred from the boxes or even beds under glass to their summer quarters, and they will do very well.

Cannas outdoors require sheltered situations. In exposed places their noble leaves are much injured by winds. They also do not like dry and shaded sites. What they want is an open or sunny position, but sheltered from winds. The soil should be deeply stirred and well enriched, plenty of moisture also being an essential of Canna culture. In planting the rootstocks should be kept down at least 3 or 4 inches and duly watered, but avoid saturating the soil until they become well established. A sprinkling over the foliage in the evening is highly beneficial, and equally so is a mulch of well decayed manure, or preferably of cocoanut refuse. When they begin to grow freely they can hardly have too much water, especially when the weather is droughty, and liquid manure applied once or twice a week will materially help them in making foliage, and by August the Canna beds will be gay. I consider that no beds of foliage plants can equal well filled ones of Cannas. Their noble foliage and flowers render them singularly pleasing during the late summer and autumn months.

After the first frost, which usually leaves its mark on the foliage, the plants may be lifted, and either potted or stored away in boxes packed with light soil and placed in dry, frost-proof places or cellars or sheds, or under greenhouse stages during winter, but having tried most plans I find nothing equal to potting the roots before the foliage is damaged by frost, and placing them in a house where they can be kept rather close and moist until the potting is recovered from, duly supplying with water. This insures the completion and ripening of the growth, and they form much finer rootstocks, which divide and start into growth much better than those that have the growth destroyed by frost, and are lifted and stored in places which are so dry that most of the life is withered out of the rootstocks during the winter. This drying and withering process is not of any use to anything, particularly Cannas. When the stems die the roots do not, of course, require to be kept wet; yet there is a difference between having moisture enough to keep the rootstocks plump and keeping "dry as dust," so as to impair their vitality if not jeopardise their existence.

In warm sheltered situations and well drained soil Cannas are said to winter safely in the open, the bed being covered with a good thickness of cocoa refuse and some litter or fern to keep out frost, about a foot thickness altogether being necessary. I have not, however, tried this plan, nor have I known any cultivator who from experience could vouch for the success of the system. These poor soils are not good for Cannas unless they are specially prepared. Where the soil is wet and cold it is much the safest plan to lift the rootstocks and store them.

Cannas are useful and effective for greenhouse, conservatory, and house decoration. For these purposes select the best plants after they have been started into growth in spring or the most sturdy and promising of the seedlings. These may be grown in 9-inch, 10-inch, 11-inch, or 12-inch pots, using a compost of turfy loam, well decayed manure, and peat in equal parts, with a free admixture of sand. I find it best, however, not to divide the rootstock so much for this purpose as for those that are intended to be planted out; therefore those grown for the purposes indicated are kept in pots constantly, and are grown as greenhouse plants, being duly supplied with water until a much later period than those that are lifted and dried, and they may be said to never be rested so far as the drying process is concerned, though they are kept somewhat dry during the winter, or from midwinter to March. When they begin to push fresh growths in spring the plants are turned out of the pots, they are given fresh and clean pots, and the roots are reduced, repotting in fresh material. Larger pots are given if deemed expedient, or they are divided if increase is needed or the rootstock is considered too large for the pots they are to occupy. A little of some approved fertiliser is mixed with the compost in potting, which gives them a start, care being taken not to overwater or make the soil sodden until the plants push fresh growths and are making roots freely, when they require copious supplies of water, and of liquid manure when the roots are fully possessed of the compost. With this and full exposure to light they will make sturdy, thoroughly ripened growth, a genial condition of the atmosphere being secured by keeping the stages well damped with an occasional sprinkling over the foliage, but not having it wet when the sun falls powerfully upon it. The only other attention requi-

site is to cut away old growths that detract from the appearance, and not to water so as to render the soil sodden, for much as Cannas like moisture, they soon become rueful objects when saturated. Give a full supply of water when it is wanted before the foliage flags, and wait until the soil or the ring of the pot indicates the necessity of its repetition. Plants grown in this way are in season from June onwards. If earlier plants are wanted they must be forwarded in a stove or warm house, but they are not half as good for decorative purposes as those grown in a greenhouse or conservatory.

SELECT VARIETIES.

For Growing in pots for Decorative Purposes.—*C. iridiflora*, broadly acuminate leaves, the whole plant attaining to a height of 6 feet or more. Its flowers are Iris-like, large, rose coloured with a yellow spot on the lip; the spikes droop gracefully, several emanating from the same spathe. *C. iridiflora hybrida* has large blood red flowers, very effective, the foliage green and bold. It also attains to a height of 6 feet or more. *C. iridiflora Ehemanni*, immense foliage of an attractive reddish hue, flowers bright crimson, perhaps the noblest of all Cannas. *C. Bihorelli*, leaves red in a young state, changing to deep bronze with age, flowers deep crimson, very freely produced, height 5 to 6 feet. *C. gigantea major*, leaves green, petioles having a velvety down covering, flowers large, orange red or scarlet, very ornamental, height 6 feet. *C. nigricans*, dark bronze stems and foliage, red flowers, one of the finest, height 4 to 6 feet. *C. Annæi*, green glaucous foliage, flowers salmon. This is perhaps the most glaucous of all the kinds. Height 6 feet. *C. Prémices de Nice*, an exact counterpart in foliage of *C. Annæi*, of which it may be a variety, flower large, bright yellow, height 6 feet. *C. zebrina*, fine deep green foliage, passing into dark red rayed with purple, stems dark violet red, in foliage very effective, flowers small, orange, height 6 feet. *C. musæfolia maxima*, fine large green Musa-like foliage with dark petioles, stately in contour, flowers orange red, height 4 feet. *C. grandiflora florihunda*, foliage dark, flowers large, red, freely produced, height 3 to 4 feet. *C. Van Houttei*, foliage green, rayed and margined purplish red, flowers large, scarlet, and very freely produced, height 3 to 4 feet. *C. Chatei sanguinea*, leaves ovate elliptic, deeply tinged purple, red flowers, height 3 to 4 feet. *C. nobilis*, leaves rayed and margined red, flowers red, height 3 to 4 feet. The two last are undoubtedly varieties of *C. Warszewiczii*, dark foliage, blood red flowers, height 3 feet. There are many other fine species and varieties, but commencing with *C. iridiflora Ehemanni*, I do not think thirteen choicer varieties exist for decorative purposes outdoors, being in respect of foliage and flowers highly effective. Cannas, however, need improvement in the direction of the flower in form, substance and size; indeed there is no reason why they should not be as remarkable for the beauty of their flowers as they are now for their unique grandeur of foliage and habit.—G. A.

RICHMOND HORTICULTURAL SOCIETY.

MARCH 18TH AND 19TH.

THE second spring Show of the above Society was opened on Tuesday last by the Duchess of Teck, and proved very satisfactory in all respects, being favoured with extremely fine weather. The Show was held at the New Castle Assembly Rooms, but the apartment devoted to it was scarcely large enough, consequently some of the exhibits were rather crowded, and a portion of the adjoining corridors was occupied. Hyacinths, Tulips, Deutzias, Azaleas, Orchids, groups of plants, and floral decorations contributed to the bright, varied, and pleasing effect produced. The Hon. Secretary, Mr. J. H. Ford, has worked hard to develop this Show and increase the local interest in horticulture, and he deserves every credit for the success achieved. Messrs. Bates, Lindsay, Brown, and other members of the Committee have also contributed materially to the prosperity of the Society by their well-directed efforts.

A prominent position was accorded to the tastefully arranged group from H. Little, Esq., Baronshalt, Twickenham, which gained him the premier prize in the class, Orchids, Clivias, Cyclamens, Deutzias, and bulbs being employed with Ferns and foliage plants. Mr. H. Williams, Finchley, was second with Azaleas, Deutzias, and bulbs; and Mr. Fordham of Twickenham was third with a bright group, but rather formal. Mr. H. Little also had the best six Orchids, comprising well-flowered plants of *Cymbidium Lowianum*, *Vanda suavis*, *Phalænopsis Schilleriana*, *Cattleya Trianae*, and *Cypripedium villosum* and *Boxalli*.

With eighteen Hyacinths Mr. H. Williams secured first honours for even plants, having grand spikes, and Mr. J. Lonsdale, Shepperton, was second. Mr. Williams was also first for six single Tulips, again followed by Mr. Lonsdale, while Mr. Williams had the first prize for six pots of Narcissi. Mr. W. Brown, St. Mary's Grove Nursery, Richmond, secured premier honours with six plants of *Dielytra spectabilis* well flowered. W. Clay, Esq., Elm Villa, Kingston, had a collection of Primulas, and secured first prize for well flowered plants. In the amateurs' classes for six Hyacinths Messrs. D. White, J. Lonsdale, and F. Lonsdale were the prizetakers.

There were four entries of twelve Cyclamens, and the competition was rather keen in regard to the two first prizes. Mr. D. White, gardener to Mrs. Farnell Watson was placed first with compact even plants, including several bright colours, and H. Little, Esq., was second with stronger plants bearing a number of large, well-formed flowers. Messrs. Williams of Finchley, and Bray of Richmond, were exhibitors of Lilies of

the Valley; Cinerarias came from Mr. D. White and Mr. Baynes, gardener to Sir J. Brunlees, Argyle Lodge, Wimbledon Park; double Primulas from Mr. Brown; Deutzias from Messrs. Little, White, and Brown also added materially to the Show. Mr. W. Brown had a capital collection of Azalea mollis varieties; Spiræas were shown by Messrs. Williams, Brown, and Bray, who gained the prizes in the order named. Mr. W. Clay of Kingston had a large collection of Cyclamens. Three good collections of six table plants were shown. Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton was first for neat and graceful plants, and Mr. Bates was a good second.

With bouquets Mr. G. Newman, 1, Broadway, Bromley, Kent, was first, having a handsome combination of Roses, Cattleyas, Lilies of the Valley, Spiræas, and Angraecums. Miss E. L. Clarke, Whitton, Hounslow, was second with a loose arrangement of Chionodoxas, White Tulips, Lilies of the Valley, and Cyclamens. Mr. J. R. Chard, Brunswick Nursery, Stoke Newington, following with a bouquet of Roses and Mahonia leaves. Stands of plants were shown by Mr. F. T. Wadhouse and Miss E. L. Clarke, who were first and second, Freesias predominating in the former, and Daffodils in the latter. With buttonholes and sprays Mr. Newman, Mr. Chard, and Mr. Bray were the prizetakers in the order named, all showing very tasteful productions. Messrs. Lonsdale and Bray had collections of Daffodils.

Mr. Wm. Bates was first with four dishes of excellent Apples, fine specimens of Dumelow's Seedling, Blenheim Pippin, Lord Burghley, and Cornish Aromatic. Mr. Wadhouse was second with Gloria Mundi, Beauty of Kent, and King of the Pippins, all well kept.

FRUIT FORCING.

PINES.—*Suckers.*—The rooting of those recently potted will be indicated by the growth of the foliage, but it is well to turn the plants out of the pots, or at least a portion of them, to ascertain the condition of the roots and the soil. The young roots which issue from suckers, or plants subjected to similar treatment, are tender and susceptible of injury from the effects of too much bottom heat, hence when the roots reach the sides of the pots 85° is ample, above which there is danger. When the bottom heat is excessive the pots may be raised, placing some loose tan under and around them, so as to allow the superabundant heat to pass away without injuring the roots. The plants must be carefully supplied with water.

Established plants now root rapidly, and soil should be prepared for transferring them to their largest pots, as it is important they be grown without check by being either dry or root-bound. Sound fibrous loam in good sized lumps is the best material for potting, pressing it firmly down and round the balls of the plants, watering the plants with tepid water, and plunging them in a bottom heat of 90° to 95° until the roots have possession of the fresh soil, when 85° is more suitable.

Fruiting plants, and those that are at or near the flowering stage should have a night temperature of 65° to 70°, and 75° by day, with 80° to 90° from sun heat, closing at 85°, well damping the house at that time. Afford succession plants a bottom heat of about 85°, ventilating at 80°, and closing at 85°, lightly sprinkling the plants occasionally.

PEACHES AND NECTARINES.—*Earliest Forced Trees.*—When the fruit are stoning too high a temperature at night is not favourable, and cold draughts in the daytime are even more injurious, therefore maintain an agreeable temperature as practicable. Continue it at 60° to 65° at night, and 70° to 75° during the day. Thinning the fruit must be attended to betimes, it not being advisable to leave during the stoning period more than twice the number of fruits that are to be left for a crop. One fruit to a square foot of trellis covered with foliage is ample. Nectarines are often left much closer, which proportionately lessens their size, whereas to secure fine fruits they require the same space as Peaches. See that all the shoots are tied to the wires as they progress, stopping any gross shoots at about 15 inches, or if very gross and likely to interfere with an equal distribution of the sap or induce gumming, remove them altogether. If the pinching results in laterals stop them at the first joint, and if extension is wanted the uppermost laterals may be trained in as a continuation. If the trees are in good order there will be little necessity for stopping the shoots, they being trained in their full length, allowing space for the development of the foliage in order to solidify the wood as made. Shoots retained to attract the sap to the fruit should be stopped to one leaf, they having previously had the growth stopped at the second or third leaf.

Second Early Forced Trees.—Disbudding must be attended to, a shoot being taken from the base of the present year's bearing wood, or last year's young wood, and one on a level with or beyond the fruit may be stopped at the second or third leaf. Upon extensions leave young shoots at 15 inches to 18 inches distance, the shoot from the extremity being trained as a continuation of the primary branch. The main shoots must be 12 inches apart. Commence tying early, as when the shoots are allowed to grow considerably they cannot be brought near to the

wood they proceed from without danger of breaking. Overcrowding must be carefully guarded against. It is fatal to fine, highly coloured fruits and the formation and perfection of the wood of future crops. Thin the fruits by degrees, leaving those well placed upon the upper side of the trellis in sufficient quantity for a crop, or a little more until the final thinning before stoning. In no case is it good practice to tax the trees with superfluous fruit after it is the size of marbles. Temperature 55° to 60° at night, 65° by day, increasing to 70° to 75°, ventilating freely between 70° to 85° if it rise to the latter, as it often does on bright mild days.

Houses Started at the Beginning of February.—The trees are in full flower or setting the fruits, and it is an anxious time. Continue to fertilise the blossoms on late trees when the pollen is ripe, as we have not found it satisfactory to trust to Nature in the case of trees under glass, which from unfavourableness of weather often have to be kept close, or with a crack of air only, for most of the flowering season. When the blossom is all set recourse must be had to syringing in the morning and afternoon, having the foliage and young fruit dry before nightfall. Disbudding may be done gradually, commencing with the strongest shoots, also thinning the fruit after it is seen which takes the lead in swelling, removing the smallest first, but avoid large reductions of shoots or fruit at one time. Temperature 55° at night, 5° less on cold mornings; 55° to 60° by day, advancing to 65° or 70° from sun.

Houses Started Early in March.—The flowers are expanding. Syringing must cease directly the anthers show clear of the corolla, but damping the floors and borders must be practised on fine days, admitting air freely in mild weather, fertilising the flowers on fine days. Maintain the night temperature at 45° to 50°, 55° by day artificially, and 65° from sun heat. Admit a little air constantly. Superfluous flowers on the under side or back of the shoots may be removed by drawing the hand down the growth.

Late House.—Lights removed in winter must be replaced at once, the buds being well advanced in swelling. Nothing assists to a good set so much as turning on the heat for a short time in the early part of the day to advance the temperature to 50°, and to permit ventilation after the flowers expand, as if there be a prevalence of dull cold weather at that time, closing the ventilators for safety produces an atmosphere that converts the pollen into paste. Houses that have fixed roof lights must have the borders rendered thoroughly moist. If there be any trace of aphides fumigate thoroughly before the flowers expand.

FIGS.—Early Forced Trees in Pots.—Those started early in December will be induced to swell their fruits by a top-dressing of rich material applied to the surface of the soil, and if a layer of turves has been placed around the rim of the pots as before advised, space is afforded for the top-dressings. Do not give heavy dressings of rich compost all at once, but apply it little and often; apply also liquid manure, 1 oz. of the soluble artificial manures to a gallon of water, but give it in such quantity as to pass through the pots. Dribbles do no good. Maintain a genial atmosphere by syringing twice a day when the weather is bright, but avoid keeping the foliage constantly wet, as would be the case by syringing vigorously in dull weather. Damp the paths, walls, and bed, keeping the evaporation troughs charged with liquid manure, and to check red spider paint the hot-water pipes with sulphur. Admit a little air at 70°, increasing it with sun heat up to 85°, which ought not to be exceeded, closing at 80°. The night temperature may still range from 60° to 65°, 55° in the morning in very severe weather is safer than the higher temperature, advancing 10° by artificial means in the day-time. Avoid crowding, stopping, or tying the shoots as growth advances, as the fruit to have flavour and colour must when ripening have full exposure to light, combined with a circulation of warm dry air.

CHERRY HOUSE.—When it is seen that the fertilising has been effectual by the swelling of the Cherries at the base of the decayed flowers syringing must be resumed once a day at present or in dull weather, and twice a day when the weather is clear and warm. Fire heat will only be necessary to prevent the temperature falling below 40° at night, and to maintain 50° by day as a maximum. Ventilate at 50°, closing at the same time, regulating the ventilation according to circumstances. If green aphides appear fumigate the house, having the foliage dry, and keep a strict look out for grubs. Stopping will soon require attention. Pinch out the points of the shoots when they have made 4 to 5 inches of growth, removing those shoots that are not required. Train extensions in their full length, also those for filling vacant space. Overcrowding must be carefully guarded against, it being prejudicial both to the present and to future crops.

THE FLOWER GARDEN.

Work in Shrubberies.—Shrubberies generally ought now to be put into good order for the season. In many instances the older ones will be much improved by having some of the ugliest overgrown Laurels sawn down to near the ground, others merely require to have some of the branches freely shortened back, while all pay for timely attention in the way of pegging down branches of Laurels, Rhododendrons, and Aucubas especially wherever the fronts are badly furnished. Where extra large Laurels are cut down it will in some cases be necessary to plant a few young bushes, and these will grow and fill the space in conjunction with the branches from old stumps much more regularly than before. Newly formed shrubberies are usually planted much more thickly than is ultimately good for the trees and bushes. Thinning out ought, therefore, to be freely resorted to, transplanting a portion of the

shrubs to where there are more needed being the wisest course to pursue. This work may be continued for another six weeks, always providing it is done well. Nor should pruning be neglected in the case of young shrubberies, as, with the aid of a knife used just now, many plants can be kept within bounds and of better form than if allowed to grow at will. All open shrubberies especially ought to be lightly forked or skimmed over with a spade, this burying much rubbish and presenting a far neater appearance.

Climbers.—The commoner and more vigorous kinds, notably Ivies and Japanese Honeysuckle, are apt to overgrow the rest, and both are objectionable when in a rough state. When either get too large or coarse it is a good plan to cut them hard back to the wall, or, better still, down to near the ground, the young growths that soon follow being far more ornamental in appearance. Ugly overgrown plants of *Crataegus pyracantha* might also be cut down with advantage, young spreading branches neatly laid in to a sunny wall invariably flowering and fruiting freely. Thickets of Clematises must always be prevented. Those that flower from young growths formed last summer should be only thinned out and lightly shortened back, but the late summer and autumn flowering species, including the well known *C. Jackmanni*, ought to be freely shortened, the aim being to secure as many strong back growths as possible. These will flower strongly. All lateral growths on Jasminums to be spurred back to the old wood, the common sweet-scented white kind flowering on the young shoots, while *J. nudiflorum* will form fresh wood for flowering next winter. *Chimonanthus fragrans*, *Pyrus japonica*, *Pomegranate*, *Myrtles*, and *Garrya elliptica* to have all straggling branches shortened back and leading growths laid in. *Euonymuses* to be similarly treated. *Magnolias* require no pruning, but must be firmly fastened to the walls. *Wistaria sinensis* to be treated similarly to Pears, the flowers being most freely produced by short spurs.

Pruning Roses.—Roses in the open were at one time more forward than those against walls, but cold winds and severe frost have effectually checked their progress. Pruning may now be safely done, both of those growing against sunny walls and in the open. The former are too often neglected, but they require to be pruned quite as much as those in the open. Unpruned they flower profusely the first season, but fail to form good growth for the following year. Therefore thin out spray, freely cut back all medium-sized shoots, and lay in and lightly shorten back the more vigorous yet well-ripened growths. Only the smaller wood will flower in the case of Banksians, and at the present time it is advisable to reserve this and remove some of the gross shoots. Quite the opposite treatment holds good in the case of *Maréchal Niel*, this flowering most freely on long well-matured growths. Standard Roses must be kept within bounds, as when once neglected it is almost impossible to get them into a presentable condition again. These ought to have the centres well thinned out, and all long shoots cut back to better placed inner growths. Next cut out all spray, as this is never of any good, then thin out the remaining shoots where these are at all thick, finally leaving about six of these, and which should be cut back, the strongest to about the ninth eye, and the moderately strong to third or fourth bud. Dwarf Roses should be either somewhat similarly treated, or the pegging down system must be adopted. In the latter case it is the long and strong young shoots that should be lightly shortened back and pegged down, the old flowering wood being cleanly cut out. The pegged-down growths will flower freely, pushing up extra fine blooms, while from the centre of each plant will spring vigorous shoots, these eventually taking the place of those pegged down this season.

Manuring Roses.—If starved at the roots, Roses need not be expected to grow strongly or produce good solid blooms. They are often located where mulchings of manure would prove unsightly, but even this difficulty can be overcome. The simplest and best plan in most cases would be to carefully remove the soil down to the roots of the plants, returning this after a liberal dressing of manure has been given. The manure being thus covered with soil, is well hid from view, that is if the birds can be kept off. It is within easy reach of the roots, and retains moisture much longer than it does when spread on the surface. Those Roses growing against sunny walls stand in especial need of a heavy mulching of manure, and may with advantage also frequently receive liberal supplies of water and liquid manure from the present time and onwards. The least that can be done for those in the open is to lightly work in a dressing of half-decayed manure, this being done directly after pruning is completed.

THE BEE-KEEPER.

NOTES ON BEES.

On the 14th of March, after four days' stormy weather, mildness succeeded the low temperature up till the 9th, and in twenty-four hours the thermometer rose from 20° to 55° with a falling barometer, which clearly foretold the coming storm. With the thermometer at 32° some of the bees were getting restless. No doubt a paucity of pollen within their hives, through so early

excessive breeding, induced them to go outside in search of more. The same thing occurs if a dearth of honey is expected. Hives that are subjected to an empty larder in winter of either pollen or honey are sure to dwindle.

By the owners of several apiaries I was asked the cause of the bees of some of their hives being so restless. I advised feeding, and a subsequent examination proved that without feeding the restless ones would have been dead—simply another proof that it is better and safer to leave the bees with plenty stores in autumn, and if necessary to remove a comb or two in spring, than having to feed them.

CLOVER VERSUS HEATHER HONEY.

For some years past our district has been converted into a dairying one, consequently there is more pasture for bees than was the case a few years since. Clover honey is more plentiful when the end of June and beginning of July are favourable, but the demand is very limited, Heather honey being when fine more in request, and probably many others are in a like position. I shall not be ungrateful for an abundant supply of Clover honey, as I have various resources of outlet for a large quantity; but I shall work my stocks, at least a portion of them, to be right for the wild Thyme and Heather. The particular management I must reserve for a future occasion, as we cannot lay down an infallible rule but must adapt everything to circumstances. What I shall keep in view, although it has to be attained in different ways, is to have every hive provided with a young and fertile queen, and the combs well charged with brood at the end of July, and an adequate supply of meat, so that neither starvation nor drawing brood will take place however adverse the weather may be. In some seasons each stock may be left to itself, but sometimes it is not only advisable to unite two but is ruinous to avoid it. Then some seasons are favourable for having a large quantity of empty combs, while the others make it a disadvantage. It is not altogether what the bee-keeper would do, but is what the seasons demand to be done, and I hope to be able to show beginners how best to get along.

I prefer if the seasons would allow to have a limited supply of empty combs below, but only in rare cases above. Instead of preserving empty combs for supers I generally melt them down. The reason for this is that when bees are supplied with empty combs but a short time before the honey flow they darken them, and this puts an end to its being first class. First class comb is most frequently had from those hives crowded with brood and bees right beneath the supers, and when the honey flow commences so does comb building and comb filling with the purest of nectar. No intermediate storage is performed, nor is it necessary. When supers filled as above they bring higher prices than what are not inaptly termed artificial products produced by modern and in many cases artificial bee-keepers.

DIFFERENTLY SEALED CELLS.

Not long since when in conversation with a young lady she exclaimed "That she would like to be proficient in bee-keeping, but there was so much to be learned I would as soon go back to a boarding school as learn all about bees, especially when there are so many conflicting opinions." My rejoinder was, Not so very much after all; select the grain from the chaff and you will find two-thirds at least not worth retaining, and the science of bee-keeping will dwindle to very little.

The variety of bees and the manner of sealing the combs were also commented upon, but I could not advise which variety to keep that left a vacuum between the seal and the honey. I have frequently taken three, four, and even five large supers from hives at one time, and the appearance of every super differed in that respect from one another, exactly what some would tell us No. 1 was from a Carniolian, No. 2 from a Syrian, and No. 3 from the native black. That is one thing I have not learned yet—how to distinguish one variety of bees' honeycomb from

another, nor do I believe it can be done. One variety uses more propolis than another does, and different flowers produce a difference in appearance in the combs built and filled with honey than do others, but as regards one leaving an air space, and another sealing hard to the honey, or employing more wax than another variety does, is not believed in nor experienced by—A LANARKSHIRE BEE-KEEPER.

THE LANARKSHIRE HIVE.

It must be very gratifying to "A. L. B. K." to see so many inquiries in the Journal about the Lanarkshire hive. Bee-keepers are slowly coming to the conclusion that the standard frame hive is not so suitable for bees as it ought to be. I tried a Lanarkshire hive last season, and was highly pleased with it. I had more surplus honey from it than some of my neighbours had from two hives of the ordinary bar-frame kind. It is easily prepared for moving to the Heather, whereas the standard frame hive requires much fastening up before it can be moved with safety. The perforated zinc floor is a capital idea, saving the bees a lot of labour, as they have no refuse to carry out. This and the ventilator ought to be in every bar-frame hive. Any of your readers who are thinking of starting bee-keeping cannot do better than make themselves one of the above hives, which they can easily do if they are handy with joiners' tools; instructions have been given in the Journal many times of late.

BEE FEEDERS.

I have tried "the universal feeder" described by "A. L. B. K." in the Journal for January 23rd, page 77. I find it answers admirably. I have no doubt that when the bees are in a feeding state they will take the syrup very quickly. Of the two I prefer the bar-frame feeder, because it is so firm. The box feeder, however, has the advantage of being suitable for placing on the top of any kind of bar-frame hive. It is strange that this useful appliance is not oftener seen, as it is far ahead of the old tin feeder with float, which is the kind of feeder that is used chiefly in this district.—C. RUSSELL, *Ingmire Hall*.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

THE annual meeting of this Association was held in the Mayor's parlour at the old Town Hall recently under the presidency of Mr. L. Fosbrooke, Ravenstone Hall. About a dozen other members were present. The report of the Committee stated that in accordance with general anticipation the disastrous season of 1888 had been followed by one productive of more than an average crop of honey. The Committee congratulated the bee-keepers of Leicestershire on their good fortune. The annual Show was held in the show ground of the Leicestershire Agricultural Society at Melton Mowbray on July 31st and August 1st. Mr. J. M. Hooker, the Judge appointed by the British Bee-keepers' Association, writing on the Show, had said:—"The Leicestershire Association have reason to be proud of the grand display of honey this year; the great uniformity of appearance and flavour made it a difficult matter to select the best, where all were good, my only regret being that I had not double the number of prizes to award in the several classes. I never saw better honey staged. It shows that the teaching of the Association has not been in vain." Nearly a ton of honey was placed on the tables. There was also an excellent display of hives and bee appliances, thanks to Messrs. Meadows & Redshaw, who gratuitously exhibited their magnificent collections of apiculture apparatus. The silver medal was awarded to Mr. J. W. Bickley of Melton Mowbray; the bronze medal to Mrs. Copley, and the certificate to Mrs. Rippin of Waltham. The hive and bees were drawn for as usual, and fell to the lot of Mr. Beazley. A second Show was held on August 6th at Leicester in connection with the Abbey Park Flower Show. The Committee very much regretted to have to point out the very unsatisfactory state of the finances of the Association, and trusted that earnest endeavours will be made on all hands to increase the income either by subscriptions or donations. Special efforts were being made to reduce the debt, and donations for that purpose had already been received from Messrs. Whetstone, Mott, Finch, Meadows, and Perkins. All liabilities except prizes had been discharged, and it was intended to make the prize money a first charge on the current year's income. Members were requested to note the change of residence of Mr. George Munday, the expert; his new address being Cromwell Road, Wigston Road, Aylestone, Leicester. Circumstances over which he had no control had compelled the Secretary to resign. It will, therefore, be necessary to appoint someone else to the office."

The balance sheet showed receipts amounting to £36 ls. 10d., leaving a deficit of £9 12s. 6½d. A short discussion followed upon the report, during the course of which Mr. T. Carter said it must be evident to all that the funds of the Association were not sufficient to enable them to meet the expenses connected with their Shows. Then, again, the expert's expenses amounted to nearly one-third the income of the Society. That was an expense that had been deliberately adopted, and to some extent they were obliged, perhaps, to continue it, because one of the objects for which the Society was founded was to instruct members in the management of bees. If they did not keep that up they would be rather breaking faith with their members, but they could not continue to conduct the Society on the present system unless some vigorous means were adopted for increasing the funds or diminishing the ex-

penses. There was no doubt the Society had done good during the time it had been in existence, and he would be very sorry to know that it had to be dissolved, but that meeting must seriously consider what means, if any, could be adopted to put the Society in a better position. Mr. Ryley thought the Agricultural Society ought to undertake the Bee Show held in connection with their annual Exhibition. If the Show benefited anyone at all it was the Agricultural Society, and they ought, therefore, to pay all expenses. Mr. Meadows suggested that similar representations should be made to the Abbey Park Committee. Attention was called to the fact that the Association, being affiliated with the British Bee-keepers' Association, was entitled to the gratuitous services of a Judge, and it was resolved to communicate with the British Association on the subject. In the end the report was adopted, and the following Council was appointed for the ensuing year:—The Rev. M. A. Thompson (Thistleton), the Rev. A. M. Rendell (Leicester), Mr. L. Fosbrooke (Ravenstone Hall), Mr. T. Carter (Leicester), Mr. W. P. Meadows (Syston), Mr. J. Cooper (Belgrave), Mr. J. Atkins (Aylestone Park), Mr. T. J. Clarke (Aylestone), Mr. J. M. Marriott (Claybrook), Mr. J. H. Shenton (Market Bosworth), Mr. T. B. Widdowson (Leicester), and Mr. J. W. Bowles, C.C. (Leicester). On the proposition of Mr. Carter it was unanimously decided to appoint Mr. H. M. Ryley (Tower House) to the office of Secretary in the place of Mr. Edwin Ball (Waltbam, Melton Mowbray), resigned. Mr. Ball was cordially thanked for his past services, and awarded an honorarium of £3 3s. The remaining business was merely formal.

TRADE CATALOGUES RECEIVED.

Charles Sharpe & Co., Sleaford, Lincolnshire.—*Catalogue of Farm Seeds and Seed Corn, 1890.*

*** All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Duration in Growth of Vegetables (Streatham).—Perhaps the article to which you refer was a portion of a lecture delivered by Mr. J. Wright at Nottingham, and if so you can have the whole of that lecture in pamphlet form free by post for 3d. sent to the publisher. We think the stock of the Ham Green Favourite Tomato was obtained for distribution by Messrs. James Veitch & Sons, Chelsea.

Gardeners' Societies (W. H. B.).—We believe the subject of your letter is under consideration by persons who will be certain to "consider it from every point of view," whether it "comes to anything" or not. Many things are desirable that are not practicable, and this may or may not be one of them. We have not much faith in new organisations of the nature suggested, and the question is whether any existing institutions can increase their usefulness.

Hollies under Trees (Cambridge).—Hollies grow very well under trees if the shade is not very dense, and especially if the roots of the trees do not deprive the Hollies of the moisture that is essential to their growth. It is often desirable to form a shallow channel for holding sufficient water that may be given from time to time to pass quite below the roots, covering or mulching the surface with manure. Bushy, well rooted plants should be obtained, and one of the best varieties for such positions is sold under the name of "Hodginsi."

Dry Glazing (G. T. H.).—Probably the system you mention would answer, as would Newton's "Reform" method, which is advertised. Orchids have been growing and flowering in a dry glazed house all the winter. You can probably obtain testimonials from the respective firms. We do not approve of rough glass for Cucumbers, but prefer it clear and of good quality. The plants cannot possibly have too much light in winter and early spring, while a little shade can be applied in summer if desirable, though we do not have recourse to the practice,

except occasionally when very bright days follow suddenly a week of very dull weather. As a rule the hotter the summer the better Cucumbers grow and bear in the open air.

Mulching Strawberries with Stable Litter (F. J.).—The stable litter, to keep the fruit clean, should be placed between the rows before the plants are flowering, as it can then be done quite safely; but it is sometimes deferred until the fruit is well advanced in swelling, when from having to move the trusses they are liable to be broken and the fruit to be damaged. It would be preferable to apply the fish manure in advance of the flowering, so that it may be washed into the soil and available for the use of the plants, whereas if given after the fruit is set it will not be so advantageous. It is advised in the prize essay, "Profitable Fruit-Growing," to give an occasional soaking with liquid manure when the fruit is swelling. You would find the wood useful, and it may be had post free from this office for 1s. 3d.

Herbaceous Plants for Cutting (Idem).—Herbaceous plants require some little time to become established before they are capable of furnishing flowers in quantity for cutting. A dozen thoroughly reliable are:—*Achillea Ptarmica* fl.-pl., *Alstroemeria aurea*, *Anemone japonica alba*, *Campanula glomerata dahurica*, *Coreopsis lanceolata*, *Erigeron speciosus superbum*, *Helianthus multiflorus* fl.-pl., *H. orgyalis*, *Lychnis dioica rubra* fl.-pl., *Rudbeckia Newmanni*, *Geum coccineum plenum*, *Galega officinalis alba*. We presume you have such plants as Pinks, Carnations, Picotees, Pyrethrums, single and double; Double Rocket, Delphiniums, German and other Iris, Peonies and Asters, Iceland Poppies, *Anemone coronaria* vars., *A. stellata fulgens*, Phlox; *Lilium longiflorum Harrisii*, auratum, and *speciosum* vars. Where cut flowers are required in quantity it is well to sow the different varieties of annual Chrysanthemums largely, also Sweet Sultan and Cornflower. The Cactus and Pompon Dahlias, Asters, &c., are very useful.

Nationality of Gardeners (Justice).—You neither say whether you are an Englishman, Irishman, Scotchman, or Welshman, and we do not mind in the least to which division of the kingdom gardeners belong, so long as they are worthy exponents of the craft, respectable members of the community, and send good and well written articles to the *Journal of Horticulture*. Some of the best positions in the kingdom are worthily filled by gardeners of every race indicated, and in proportion to population Irishmen and Welshmen contribute as well to this Journal as do Englishmen and Scotchmen. There are representatives of all on its staff, and we do not know of a happier family. We hope friendly rivalry will continue, and a common bond of brotherhood exist, and be increasingly strengthened amongst gardeners everywhere regardless of origin or creed. This, too, we are convinced is the wish of the overwhelming majority, including yours—If, and we feel sure that on reflection you will conclude we make no mistake in not publishing your letter.

Tomatoes (Grower).—If you have no worse samples than those sent we should have no fear about the plants not thriving under good management. They are not quite so firm as we like when planted, and you will perhaps not err in letting them remain in the pots another week or ten days. The slight discoloration is, we suspect, the consequence of a temporary check to free sap movement, and we should have no hesitation in relying on the plants for bearing a good crop of fruit. We have not had occasion to try a "mixture of carbolic softsoap and sulphide of potassium" as a dressing for Tomatoes, and if you use it we advise you to proceed cautiously and experimentally with a few plants that you can afford to injure or destroy. The manures you mention are good for Tomatoes, but though you name the quantities you propose using the extent of ground is omitted, therefore we are not in a position to form an opinion on the suitability of the application.

Peach Leaves Scalded (W. J. B.).—We have Peach trees trained to the uncoloured brick wall of a house, and the foliage is quite firm and healthy. We do not know whether what may have been a strong application of Fir tree oil to the wall recently would affect the leaves, but it is never advisable to apply needlessly strong applications of anything to anything when the object in view can be accomplished by weaker. Are you certain that the roots of the trees are equal to their work of imbibing moisture to meet the demands of evaporation? This will be greater than from the trees on the trellis, and more water is required in consequence. The trees may need to be syringed earlier in the morning, in order that the water is dissipated before hot sun reaches them; also sooner in the afternoon, that they may be dry before night. The leaves sent lack substance, as if the trees had been too heavily cropped last year, and if the leaves were similarly injured then it is not unlikely the crop should have been lighter proportionately.

Growing Mushrooms (G. J. B.).—If you cannot obtain suitable manure you cannot grow Mushrooms, and though a man expert at the work would make it pay, even if he paid the prices you name, a person without experience could not be expected to do so. He might or might not succeed, as there is so much difference in the aptitude of individuals in following instructions. We know a person who pays 7s. 6d. a load for manure and a man for doing all the work, who finds Mushroom growing very profitable, and he would not relinquish it if he had to give 10s. a load for the material, provided it was well adapted for his purpose. The failure you mention was probably not so much the consequence of inferior spawn as of low temperature and possibly weak manure, for it

loses strength by very long preparation. What you collect should not be placed in large heaps to heat violently long before making up the beds or ridges, but should not be spread so thinly as to become cold and drenched by heavy rains. If it can be protected from these in an open shed or under some improvised shelter all the better, but this is not necessary in dealing with large quantities that can be got together in three weeks or a month. The question of increasing and decreasing heat is very simple. So long as a stick inserted in the mass gets hotter day by day do not insert the spawn; when the greatest heat has been attained gradual cooling will follow, and there will be no material increase after that, though sometimes when the spawn commences running, the heat rises a little, but this can be regulated by the better covering. The sixth edition of "Mushrooms for the Million" is much larger and better than the first. You should procure a copy and read carefully. Its price is 1s. 2d. by post from this office.

Reading and Working (A. B. D.).—We are pleased to find you agree with us, and we agree with you that great pressure of work must often of necessity leave too little time for reading. We doubt if there is a body of men engaged in any other occupation who work so earnestly and read so diligently as the best gardeners do. We are quite aware that many persons who are employed in gardens, and we regret to say many young men, are the reverse of studious, and prefer to spend much more of what they earn in the frivolities of life than in providing themselves with current and permanent garden literature; but the fact remains that the most intelligent, best informed, and best situated gardeners are men who in their youthful days were zealous in acquiring information. We are very far from suggesting that young men should debar themselves of wholesome and healthy recreation—on the contrary, reasonable enjoyments, in which the mind is for a time diverted from labour, may be conducive to effectual study; but the point we desire to enforce is that the first and primary object of all should be the acquirement of knowledge, both by reading and working, that will fit them for the best positions in the gardening world. If these are not obtained the knowledge gained will never be regretted, while the possessors of it who have to work hard for, it may be, the reverse of high wages will become respected members of the community. We like the tone of your letter very much, as it indicates diligence in duty, with prudence, and the possession of a good share of that most valuable acquisition—common sense.

Nectarines not Stoning (W. B.).—One of those tantalising difficulties and annoyances that beset the most skilled and experienced cultivators is the casting of fruits without apparent cause when the size (as in this case) of pickling Walnuts. The trees are apparently clean and healthy, the wood is not unduly vigorous, and it is firm and well ripened, but still the fruit does not pass the first stages of the stoning process satisfactorily; half, or more than half, the fruits fall suddenly and unaccountably. We have had several cases of a similar nature to contend with, and have invariably found it most prevalent in trees to which nitrogenous manures had been mostly employed. These have a tendency to promote vigour of growth in the early stages. The vigour may not be striking, but it is decided and sufficient to cause abortion. Nothing can be done in the season of growth to prevent its effects on the current crop, although it may be mitigated in severity by allowing disbudding to stand over until a later stage than usual, and remove any growths that are unduly gross. This will effect a higher elaboration of the sap and assimilation by the larger leafage, thereby affording a larger supply of the stone-producing matter to the fruit, and taken in time this mostly proves satisfactory. The remedy, however, is to be looked for in judicious applications of potassic and phosphatic manures in place of ammoniacal or nitrogenous manures, with applications of gypsum, so as to afford lime or preferably ground mineral phosphates (coprolites), and lifting annually until the tree is brought into a thoroughly satisfactory condition, when biennial or triennial lifting may only be necessary. The lifting in all cases should be done when the wood and buds are mature, but whilst the leaves are upon the trees, performing the operation very carefully, so as to give as slight a check as possible, making the soil firm, adding old mortar rubbish, or preferably clay marl if the soil is deficient of calcareous matter.

Insect Eggs on an Apple Tree Branch (Inquirer).—The eggs are those of the Lackey Moth Bombyx (Oligocampa) neustria. Miss Ormerod gives the following description of the pest:—"The eggs are to be found in winter and spring, laid on naked twigs, in compact spirally arranged rings about half an inch long. From these eggs small black hairy caterpillars hatch about the beginning of May, and immediately spin a web over themselves, which they enlarge from time to time as needed for their accommodation. In these webs they live in companies of from fifty to two hundred, and from them the caterpillars go out to feed on the leaves, returning for shelter in wet weather or at night. When alarmed, they all let themselves down by threads, either to the ground, or else after hanging in the air till the alarm is past they go up again by their threads to the tree. When full fed, which is about mid-summer, they are 1½ inch in length, and hairy; of a bluish-grey colour, marked with two black eye-like spots on the head, two black spots with a scarlet space between them on the next ring, and three scarlet stripes on each side and a white one on the back, all bordered with black along the rest of the caterpillar. At this stage the caterpillars no longer live in companies, but each finds some sheltered spot, between leaves, in hedges, beneath the bars of railings, under roofs of sheds, or even on the top of walls, where it spins a sulphur-coloured silken cocoon, mixed

with sulphur-coloured powder and with hairs from the skin woven into it, from which the moths hatch in July. The moths are variable in colouring, mostly with rusty fox or ochrey markings, but some have the fore-wings of a red-brown, with two pale ochreous streaks; others yellowish, with dark brown bars; and others are variously tinted; the hinder wings are reddish-brown. It is stated that the moths, and especially the females, seldom fly, but remain concealed by day under leaves and in long grass, and come out at night. The caterpillars seldom do the enormous quantity of mischief with us that they are noted as causing in France, where, according to the old law, it was compulsory on proprietors to have the webs on the shoots cut off with shears and destroyed, in consequence of the ravages of the caterpillars (if left unchecked) ruining the Apple leafage over an extent of miles of country; nevertheless their attacks are often the cause of much loss in this country, and need attention."

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*H. P.*).—1, *Adiantum cuneatum* var. *gracillimum*. 2, *Adiantum cuneatum*. (*R. A. C.*).—*Leucojum vernum*. (*G. T.*).—*Chionodoxa Lucilæ*.

COVENT GARDEN MARKET.—MARCH 19TH.

MARKET still very quiet with early forced goods in fair supply, and prices barely maintained.

MANGOLDS.

For its full development this crop requires a season of about five months; but excellent crops may be produced in four months, and this valuable root is worthy of a trial in every locality where that period of genial weather may be relied upon. Very useful roots are to be had in the shorter period, but there is no doubt that in a favourable climate autumnal showers impart much additional weight to the roots, and the best crops of Mangold are obtained where the sowing is possible early in April, and the roots are not clamped till the middle of October. We were able to manage this at our home farm last year, and we certainly never had a better crop.

In very fertile soil Mangolds answer well if sown upon the flat; but we have a decided preference for sowing upon the ridge, because of the greater certainty of a crop. With the roots established in moist rich farmyard manure growth goes on steadily through vicissitudes of weather which, to say the least, do much harm to the crops on the flat. The Mangold is a gross feeder, and it is useless to attempt its cultivation without plenty of manure, or rather in soil that is deficient in fertility. A reliable authority has shown that the chief manurial elements withdrawn from the soil by a full crop per acre is of nitrogen 147 lbs., potash 300 lbs., and phosphoric acid 52 lbs. Well, but farmers are not chemists, and we will not ask them to enter upon difficult calculations as to the precise quantity of each of these essential elements of fertility which they must place in the soil before sowing the Mangold seed, but rather to consider the condition of the seed bed, and endeavour to form a sufficiently clear idea of its manurial requirements. If it had a full dressing of chemical manures for a corn crop last year, and has had annual dressings of manure previously, then from fifteen to twenty cartloads of dung in the furrows will suffice without any addition of chemical manures; but if the soil is so exhausted of fertility as to contain very little residue from former applications, then both dung and chemicals are indispensable. We repeat the formula of chemical manures per acre which we gave on page 100— $\frac{3}{4}$ -cwt. muriate of potash, $1\frac{1}{4}$ cwt. nitrate of soda, 2 cwt. steamed bone flour, 1 cwt. common salt, and 1 cwt. mineral superphosphate.

The process of cultivation is as follows:—Make the furrows 30 inches apart with the double-breasted plough, place the dung evenly in the furrows, cover it by splitting the ridges with the same plough, press down the ridges slightly with a light roller, drill the seed (7 lbs. per acre) with the chemical manure mixture, follow with the light roller to press the soil well upon the seed. In mixing the manure for drilling the nitrate of soil must be well broken up with the back of a shovel, and the entire mixture passed through a sieve to prevent any stoppage of the drill. A sharp look out must be also kept in sowing, to see that seed and manure are sown in a regular uniform manner. Negligence in this matter is bound to appear eventually, every stoppage of a coulter leaving a blank space in the rows, which is subsequently in evidence throughout the season. Weeds and Mangolds spring up together, and the hoes must be at work soon after the plant is fully visible along the rows. A rather light quick-stepping horse and a light patent expansion horse hoe are best for this work between the rows, and hand-hoeing of the rows and plant-singling should all be paid for by the acre, the minimum outlay for hand work being 6s., any increase in the cost being caused by the foulness of land, for there must be persistent hoeing till the weeds are got under. More than once we have tried to withdraw the hoes during the hay-making, but this cannot be done if the land is foul, and it is much

better to keep the hoes steadily at work, for if they are once withdrawn haymaking is so engrossing that it is difficult to arrange to spare any of the men from it till it is ended.

Repeatedly have we seen it advised to withhold nitrate of soda from the sowing, and apply it subsequently as a top-dressing after the plants are up and growing freely. This is a mistake, because the action of soda so used is very speculative, and in a drought it would do no good; but drilled with the other manure and the seed, it enters the soil sufficiently for its moisture to act upon it as a solvent, and there is no possibility of any serious loss of nitrogen then.

Do not forget that our object is the dual one of obtaining a full crop of roots for winter food, and a thorough cleansing of weeds from the land. This is really a sensible sort of fallow, by means of which we get rid of weeds without any thought of such folly as resting the soil. On the contrary, it is stored with sufficient fertility for the demands of the Mangolds, and there is an ample residue left for the corn crop which follows next season, to this there is some slight addition from the Mangold leaves that are ploughed in immediately after the crop is cleared off.

WORK ON THE HOME FARM.

As the Turnip folds are finished the ploughs follow closely and the corn sowing is done at once. Where the land is at all heavy and a fine seed bed for Barley is doubtful, Black Tartarian Oats are now used as a more suitable, more certain, and more profitable crop. We recently heard it laid down that sheep-folding was a good preparation of land for Oats. Why, of course, said one, and we were only too glad to find Oats were taking a legitimate place among other crops, and that really good land was being used for them. Land intended for Mangold that was not ridged in the autumn has had the duck-foot harrow over it two or three times to break the cap and render it friable for the seed. A few hours' exposure to wind and sun then brought it into capital condition for the ploughs to follow. The dung carts are busy on every favourable opportunity carting dung from the yards to the furrows, and the work is so forward that we now feel tolerably assured of being able to get in the seed early next month.

The area of land usually devoted to roots will be much reduced on the heavy land farm this year, and forage plants are being sown instead for silage. Our special aim in this work is a heavy crop ready for clearance between haymaking and harvest. Calculations may be made with tolerable certainty, as silage requires no harvesting. All we have to do is to get as heavy a crop as we can, to mow, stack and press it right off when it is fully grown. Simple enough, is it not? We may add that it is equally sure, and we may give expression to a feeling of certainty that tenant farmers of such land will eventually discontinue cultivating expensive root crops and turn altogether to silage for their chief supply of winter food. The usual mixture of Oats and Tares with the addition of a bushel of Italian Rye Grass makes splendid silage if sown now and stacked in July. We have recently had pleasing evidence that our advice about silage has been turned to good account, and we would urge all who can spare a few acres of land to give it a trial. The whole thing is a certainty, and it forms a wholesome, nourishing addition to the dietary of both sheep and cattle at a nominal cost in comparison with that of hay and roots.

ERRATUM.—In the Home Farm article last week, page 232, the following mistake occurs:—In Mr. Sanders Spencer's dietary for pigs "Broad Bran" has been printed "Broad Beans."

REMARKS.

9th.—Generally fine and bright with one or two showers of snow or hail.
 10th.—Very wet till 10.30 A.M., then dull and drizzly; fair evening.
 11th.—Generally cloudy in morning; bright afternoon and evening.
 12th.—A lovely spring day; mild and almost cloudless.
 13th.—Overcast throughout.
 14th.—Slight fog till 10 A.M., then bright.
 15th.—Cloudy early; bright and fine after 11 A.M.
 A week of fine spring weather. Temperature 8° above that of the preceding week and nearly 5° above the average.—G. J. SYMONS.

FLORIDA AS A HOME.

AS regards climate Florida is one of the best favoured countries in the world. Since the termination of the great American civil war fruit culture has taken the place of that of cotton, the mild climate and balmy atmosphere of this beautiful Southern State being most congenial to the requirements of the Grape Vine, Orange, Peach, Strawberry, and other fruits, the culture of which is the chief industry of the country, and is annually increasing in importance. Florida, however, is no country for a regular farmer. Cattle run wild in the woods; hogs also, and such hogs! They go by the name of razorbacks, and are appropriately named, for they are almost as thin as a razor on edge. Having to live on anything they can pick up in the woods they fare badly, and consequently are in the habit of sneaking around cultivated groves at night, and if a loose picket or rail can be found in the fence in they go, and if there are any "Sweet Potatoes" within a quarter of a mile the razorbacks will root through the rows from end to end. As the country is now becoming rapidly settled, many coming in from Northern States, considerable agitation is going on, and an attempt is being made to pass a herd law to compel the owners to keep their cattle and hogs within their own land, and prevent trespass and damage. The passing of this very desirable Act is only a question of time. Local markets for farm produce are limited, the population being too small, consequently fruit growers have to rely on northern and western markets for disposing of their produce. The first crops of the year are Strawberries, the second crops of the year are Peaches. Here we grow the earliest Peaches in the United States, and a grove of the earliest varieties will realise a very good income in spite of the excessive railroad charges for conveying them to New York, Boston, Philadelphia, Washington, Baltimore, and other northern and western cities.

Strawberries are extensively grown in this vicinity (Waldo) and also at Starke and Lawtey in the adjoining county Bradford. Hundreds of acres of the Nunan Seedling and Hoffman Seedling are grown, and as the land is heavily fertilised with commercial manure the crops secured are enormous, and for the earliest shipments 1 dol. to 75 cents. per quart are realised. The later shipments realise 50 cents., or 2s., down to 15 cents., or 7½d. per quart. Below that price few are shipped, as the transportation charges swallow too much of the amount which the produce commission agent gets for them, and the growers then sell all they can in the local markets for preserving, or canning as it is called here, and use the remainder for home use. Most of the Strawberry plantations are mulched with Pine leaves, or Pine needles as they are termed. These keep the ground moist and the fruit from the sandy soil, and so the berries are picked clean and in fine condition. I have travelled considerably both in Europe and on this western continent from extreme northern New York to the republic of Salvador in Central America, indeed as far south as the Isthmus of Panama, which I have crossed twice, but nowhere have I seen any climate where Strawberries bear fruit continually from the middle of January to the middle of June except in Florida. Last year, 1889, I took down into Waldo the finest Strawberries ever seen in the town raised from seed of Filbert Pine sown the previous July under the shade of a thin canvas, which prevented the young tender leaves being scorched by the hot sun of August. These seedlings were planted out in rows in October, and the plants were fringed

round with berries as close as they could hang, and appear to be much more prolific than the American varieties. Thanks to friends in England I am now growing all the best early, midseason, and late varieties cultivated in the mother country.

The earliest Peach to ripen in Florida is the Peen-To, or Peen Tau, imported some years ago from Australia by Mr. Berkman, a nurseryman in Georgia, and is now in almost all parts (except the extreme south) of the State. This is a flat Peach, like an Apple, very much flattened at the eye and stalk, and contains a small round seed slightly flattened at both ends, like the Peach itself. The flavour is very refreshing, is sweet, with a very slight trace of bitterness. It is said by some to be of Chinese origin, by others from Afghanistan, "having been seen growing there by Aitchison." Many seedlings of this Peach have been raised in this neighbourhood, most of them being the ordinary Peach shape, and some of them are a great advance in quality, size, and flavour. Amongst them may be named Bidwell's Early, Kite's Seedling, Yum Yum, Maggie, Dickerson, and The Waldo—the last not yet generally disseminated, and if it continues its present free-bearing character will be numerously planted. I have seen this week (first week in March) shoots 18 inches long, which are the growths of buds inserted into an old Peach tree last summer, now bearing twelve Peaches within a space of as many inches on the branch. The second Peach to ripen of a distinct race from the Peen Tau and its seedlings is the Honey Peach, said to be from Japan. The fruit is of moderate size, highly coloured, with a curved suture at the point; is very sweet, without any acid, and by many would be considered insipid. This Peach has evidently been used to hybridise the Peen Tau, and has resulted in the seedlings already named. To illustrate the precocity of Peaches here and their free-bearing characteristics I may just mention that it is a common practice with this variety to plant Peach seeds in February, and in May the following year get a small crop of a dozen or twenty Peaches from the seedling tree.

Following the strains of Peaches already named (Peen Tau and Honey) come Dickerson, ripening in June; Onderdank, July; Freestool, August; and for canning and evaporating September Peach, Thomas Peach (October), the individual fruits of which frequently attain to a weight of 1 lb.; November Peach, as well as other numerous varieties of less note, ripening every month from the middle of May to the end of November, the several varieties being planted in separate rows 15 feet apart, and at the same distance from tree to tree in the row, according to their time of ripening. The earliest Peaches shipped, of course, realise the best prices. When the main crop is being sent to market a clear profit of 1 dollar per crate, containing one-third of a bushel of fruit, is as much as can be obtained after all expenses of picking, packing, crates, transportation and commission charges are deducted. As the trees are very prolific Peach growing pays even at the sum indicated, and as the rates of transportation are about to be reduced the growers will henceforth secure more money for their crops.

There is a fine opening for gentlemen of capital to start a large plantation of two or three hundred acres of Florida native free-stone Peaches for preserving and evaporating. There are large tracts of land, formerly cotton plantations, but which have not been cultivated since the war between North and South. This ruined thousands of cotton planters in Florida, whose capital consisted solely of land and slaves, and the Act of Emancipation left them without the means to work the land, which can now be bought from 10s. to £1 per acre. These places are, however, eight to twelve or fifteen miles from the railroads, which accounts for the low price of the land. The ground thus neglected has become covered with Pine saplings, and would require clearing again, but the cost would be infinitesimal in comparison to clearing the regular forest land. Peach trees can be bought for five cents to ten cents (from 2½d. to 3d.) according to the variety, and as they are

planted 15 feet apart each way, it would require 193 trees per acre. Negro labour can be had for fifty cents (2s.) to one dollar (4s.) per day without board, and in consequence of the soil being of a loose sandy character a much larger area of land can be cultivated in a day than in other States, where it is of a stiffer nature.

An evaporator would be required which would dry from fifty to 100 bushels of Peaches per day. This could be obtained for £20 or £30. The Peaches being planted in varieties as indicated to ripen following each other, the rush of drying would not all come at once, as there are, as already stated, many suitable varieties ripening in different months, and other varieties are continually being discovered in out-of-the-way places, and propagated by nurserymen who are always on the look out for Peaches of this class, whether new or old.

An idea of the paying character of a large orchard of this kind may be obtained by ascertaining the price of a pound of dried Peaches in one of the many good stores in England. If the fruits grown here were evaporated, boxed up, and shipped direct to England to some good wholesale firm all intermediate commissions might be saved.

As to the time the trees would take to reach a bearing state I have an instance in mind now, where a man planted in January, 1884, 200 Peach trees budded a few months before (about September, 1883), the buds being dormant at the time of planting. In April, 1884, the buds had all grown, making bushy plants. The ground was then fertilised with artificial manure. In May and June of the following year the trees bore sufficient fruit to pay for the cost of the trees, cost of planting, and cost of the fertiliser, and the following year, 1886, the net or clear income from these same 200 trees was 40 dols. He used all the fruit he required himself for dessert and preserving, and also made a barrel of vinegar.

The Loquat, which is incorrectly known in the Southern States as the "Japan Plum" or "Japan Medlar," ripens in April and May, and is a very refreshing slightly acid fruit, but good crops of this fruit cannot be depended upon every year in consequence of the blooms being partially (sometimes totally) destroyed by the slight frosts we have in December, January, and February, which is not, however, severe enough to injure Orange trees materially, the youngest tender growth only being cut off.

Figs are perfectly at home in Florida, many varieties being grown, and all succeeding well. The varieties grown are White Celeste, White Marseilles, Brunswick, White Genoa, Blue Genoa, Brown Turkey, and Black and Green Ischia. The trees bear good crops, but very few large plantations of Figs are made, the people only growing a few trees for the fresh fruits for their own use. Whether Fig culture can be made a paying crop, either as fresh fruit for shipment or for drying and boxing, is yet to be proved. The Mulberry and Pomegranate trees bear splendid crops of fine fruit every year.

The Kaki (*Diospyros kaki*) is one of the most successful of the imported fruits, and splendid crops of it are grown about Waldo. The trees are so prolific that they are sometimes killed by being allowed to ripen too heavy crops annually. The Kaki grafted or budded on the Florida native Persimmon (*Diospyros virginiana*) and a bud or graft one year old from the time of budding or grafting is 7 to 8 feet high and 2 feet through, with fine glossy leaves and covered with fruit buds all along the stems. Yemon is the variety most generally grown, and in appearance is very like a well-grown specimen of the Trophy Tomato. Hachiya is the largest of all cultivated varieties of the Kaki, exceptionally fine fruits sometimes weighing as much as 20 ozs. Growing this fruit is likely to be one of the best paying industries in Florida, as there are so many luscious varieties, and when it becomes better known it is sure to have a large sale.

In many varieties, both European and American, Grapes are grown and succeed as well in Florida as anywhere in the United States. On this side of the Atlantic the foes of the Grape are

mildew and black-rot. Grape-growing is a great industry here, but as I have already covered more space than I intended, my remarks on this luscious fruit can be briefly given in another paper. However, in concluding this, it may prove interesting to state that we have been gathering Roses of the Maréchal Niel, Belle Lyonnaise, Niphetos, Sunset, Queen of the Bedders, Gloire de Dijon, and William Allen Richardson, some of one variety every alternate day since the middle of January. We also have been enjoying large solid heads of crisp Lettuce. Paris White Cos, as large as good sized Cabbage, and although it has been so dry (only having had rain once) since the Lettuce seed was sown, strange to say nothing is suffering, the dews are so heavy that Cabbages are as though sprinkled with diamonds or silver frost at six o'clock in the morning, and the dew can be heard dripping slowly from our shingled roofs. A hot and moist atmosphere is seldom experienced here.—W., Waldo.

BUSY TIME IN KITCHEN GARDENS.

OVER-ZEALOUS gardeners and inexperienced amateurs are apt to make at least two very great blunders, for both of which they are almost certain to pay rather dearly. Many err greatly in sowing seeds in too great a hurry, and not unfrequently too thickly. We have had a comparatively light rainfall this year. I do not remember ever seeing clayey soils in such excellent working order in February, and had we been so disposed the bulk of the seed sowing and Potato planting might have been completed then. But instead of being tempted into committing that blunder we preferred rather to fork over much of the already well pulverised ground, so as to bring what lumps there were underneath to the surface, these also being in a finely divided state. Ground thus well prepared will not only be favourable to the germination of seeds generally, and well fitted for the reception of the delicate tap roots, but it will also stand against either a very wet or very dry summer better than would have been the case if we had been misled by the state of the surface only.

The last few days in February and the beginning of March were of such a wintry character as to quite damp the ardour of many who had made up their minds to commence seed sowing in good earnest, and on the whole this sudden burst of exceptionally cold weather must be considered as a blessing in disguise. A fine seed bed is in all cases desirable, but warmth is a most important factor in the strong and even germination of seeds, as well as in the rapid growth of tender seedlings. Any in the act of sprouting or even further advanced will have fared badly in the late severe weather, and it may be desirable to raise plants of several vegetables under glass for early crops. Seeds of Broccoli generally, Cauliflowers, Savoys, Chou de Burghley, and Borecole, if sown in the open late in March or early in April may produce plants large enough for putting out long before the ground is ready for their reception, and are practically spoilt accordingly. Better by far defer sowing till the end of April or even early in May, and in this case there is a much greater likelihood of all being planted before they become too tall to move or do well.

Marrow Peas especially are liable to decay if sown in cold heavy soils much before the middle of March, and it is unwise to bury many seeds of Kidney Beans before the third week in April, while the still more delicate Runner Beans may well be kept out of the ground till the first week in May. If either are wanted earlier raise the requisite number of plants under glass, transfer to the open in due course, and protect from frosts and cold winds. Should large Onions or Leeks be needed, sow seed of suitable varieties in heat; but an even and serviceable crop of bulbs can best be assured by sowing the seed on well-prepared ground at the end of March or early in April, in preference to doing so much earlier, or when most generally advised. Beet, other than a pinch of Turnip-rooted for an early supply (this being sown early in April), ought to be kept out of the ground till late in that month or early in May, or there is every prospect of the crop being both patchy and coarse; nor, for the same reasons, should the main crop Carrots be sown long before the end of April, this also being a good time to get in Salsafy, Scorzonera, and Chicory. Only small quantities of early Turnips ought to be sown at one time till July is reached, when there is less likelihood of premature seeding taking place.

We know from experience gained that it is easy to err in planting Potatoes too early. In order to obtain an early if light crop a few rows of a quick-maturing variety may well be planted on a warm border or in any convenient sunny position, the haulm in this case be protected in some way; but the bulk of the early varieties ought to be kept out of the ground till late in April, or even

the first week in May. The start should be made with the later varieties, following these with the second earlies, and finishing up with the Ashleafs. Thus treated there is a possibility of all escaping spring frosts, and which are so prejudicial to the crops of Potatoes.

Whilst deprecating sowing seed too thinly, as this may end in disappointment, I wish especially to condemn the wasteful and unwise practice of sowing it very thickly, the only exception being in favour of Mustard and Cress. In most cases it is necessary to sow rather more thickly than it is advisable that the plants resulting should remain, there being so many insect enemies, birds, and other contingencies to provide against; but that is no excuse for rushing to the other extreme. Crowded rows or beds of plants involve much additional labour in thinning, while the plants reserved are much weakened by close contact with their neighbours, and badly loosened when the thinning-out takes place. Too often the latter process is deferred unduly, or it may be not carried out at all, and in any case if more judgment had been exercised when the seed was sown the ultimate results would have been more satisfactory.—W. IGGULDEN.

INSECTS OF THE FLOWER GARDEN.

(Continued from page 150.)

STROLLERS along the paths of a country garden in the dusk of a spring evening are frequently saluted by the hum of the common dor, or watchman beetle (*Geotrupes stercorarius*), which has, in fact, no particular business to be there, but it is somewhat erratic, and appears at times to wander about aimlessly. Another peculiarity of the species is, that although it is an insect of the night, it will now and then take excursions during daylight, incurring perils from its inability to guide itself about, so often getting knocked down, perhaps trampled upon. It is a harmless visitant to gardens, the object of its peregrinations is a search for cow droppings, amongst which the eggs are deposited, and the larvæ or grubs feed. I have mentioned this species, because I find some persons fancy the beetles injurious to flowers or buds, as certain beetles are, but the dor eats nothing at all.

The species next to be described is indeed a destructive insect in all its stages, though I fancy it is less abundant now than formerly, decidedly less common than on the Continent, where beetles and grubs are frequently swept up in bushels. This is the cockchafer (*Melolontha vulgaris*), the life of which, as a beetle, does not last many weeks, though in that time it makes some havoc amongst trees and shrubs by devouring their leaves in those places where it occurs. But it is the larva that is responsible for damage done to some of the lawns in our gardens, also attacking fields of grass and corn, receiving in some countries the name of the "white grub." It lives deep in the soil, feeding upon the roots, and feeds ravenously for three years, probably having a short period of repose in the winter. This is a remarkably plump grub, when unearthed it appears feeble, but is not really so; the legs are small and not much used, its chief implement being the mouth, which has sickle-shaped jaws. One of the best means of destroying it in grass plots is the application of diluted ammonia, put on when the ground is moist. Birds eat them eagerly, but only a few, like the rook, are successful in digging them out. On the Continent this larva is reported to attack the roots of Vines, also those of many choice plants in nurseries; no instances of this kind, however, are recorded in Britain, so far as I can ascertain.

The garden beetle, or bracken clock (*Phyllopertha horticola*) is quite as much at home in the flower garden as in the orchard, though I do not know that it shows partiality for any species of Fern, so as to explain the second name. A third name for it is the June bug, that being the month when it visits fruit trees, gnawing the young fruit, and in gardens bites the petals of the Rose and some other flowers. This beetle is about half an inch long, with dark green head and thorax, the wing cases are reddish brown. If alarmed, they assume a rigid position as if dead, sticking out the legs right and left. It is a good plan to look after them with a lantern in the evening, where signs of their doings are noticeable. The larvæ or grubs feed, like those of the cockchafer, at the roots of various plants. Apart from the frequent appearance amongst our beds and borders of the beetles we now reach, forming the group of the click or skipjack species, I should have no doubt that their larvæ were injurious to our flowers, from the well-known voracity of these pests, and their tendency to spread themselves in all directions. Then in the flower garden they escape notice for several reasons, and when they are perceived they are sometimes taken to be false wireworms—i. e., millipedes, of the genus *Julus*. These have the same narrow elongated bodies as the larva of the skipjack beetles have but they are not quite so wiry, also the legs

are numerous, while in the true wireworms there are only six, very short. The death of many perennials is to be attributed to the unseen proceedings of these wireworms, which, commencing by an attack on the roots of a plant, afterwards make for the crown or stem, and which they penetrate, and the plant soon declines.

Of the various species of *Agriotes*, such being the scientific name for these beetles, I believe the grey and black species, *A. lineatus*, is commonest in our beds. Its larva has been noticed swarming in leaf mould, from which, if overlooked, it can easily migrate to the plants placed in this substance. Many have been the methods suggested for the destruction of wireworms. It is not easy to kill such tough insects and yet leave the rootlets of the plants unharmed. Gas lime, diluted so as not to injure the plants, does not affect the wireworm; one of the best remedies is irrigation with the compound liquor of petroleum, which has been already fully described here. From the wireworm tribe we proceed to a small division of soft-bodied beetles with serrated horns, some of which are abundant in flower gardens. One of the insects in this group that has a familiar history is the glow-worm, sometimes supposed to be the only luminous British insect, but this is not the case. Recent observations have proved also that the winged males possess a light as well as the wingless females and the larvæ, which light they can conceal at will. This species is generally found in lanes or grassy banks near woods, but I mention it because entomologists have suggested the species should be introduced into gardens, and it would be a pleasant sight to see a lawn or flower bed lit up by these pretty insects on a summer evening. An instance has been given of a glow-worm having been kept alive for months in a garden, and probably if secured from some of their natural enemies of the bird order they might increase rapidly. Moreover, it is certain they would be useful insects, because the principal food of the glow-worm is small snails and slugs.

Allied to the glow-worm are the beetles of the genus *Telephorus*, of which Britain has twenty species. They are familiar to young and old during the sunny season of the year, when we see them crawling upon the heads of umbelliferous plants, or on showy flowers like the Dahlia and Sunflower. Although they can fly they are best at running, and when in the air they are easily caught by the hand. The children have long named the two groups of them "Soldiers" and "Sailors," the former being of red hue, the latter blue, or blue with black markings. In habit they are alike, being active and carnivorous, killing a variety of small flower-haunting insects. It was a favourite trick with boys to match a soldier and a sailor, for though relations the beetles are quite ready to combat each other, indeed two of the same species will fight till one is a slain. However the *Telephori* rank amongst the useful garden insects, both as beetles and as larvæ, for in the larval state they live amongst grass and low herbage through the winter and spring, preying upon earth worms and other grubs that may fall in their way. I have now and then heard in a garden shed or tool house the curious tap of a tiny beetle belonging to this family, bearing formerly the ominous name of "death-watch," in science it is *Anobium striatum*. The sound is wonderfully loud for the size of the insect, and it is supposed to be made by the beetle when boring to discover how near it is to the surface of the wood, or else as a signal from one to another. Some very pretty though not large beetles of the *Clerus* family illustrate another aspect of beetle life. The native insects are fond of displaying themselves in gardens, but their larvæ live in the resorts of other insects. Some of them live in the tunnels made by the grubs of other beetles; one curious species, called *C. apiarius*, is notable because its larva is a foe to the hive bee, creeping from cell to cell and devouring the bee grubs. How the parent beetle manages to deposit the eggs without the bees interfering is rather mysterious.—ENTOMOLOGIST.

BOUVARDIAS.

My thanks are due to your correspondent, "T. S.," (page 156) for his criticism of my article on this subject on page 12. His chief remarks are in favour of planting out Bouvardias, and he regrets I did not say more about this method of culture. I am glad that I did not, for your correspondent has described a method that is excellent in every way, and one I could readily follow with certainty of success if I favoured planting them out. I have grown them planted out much further north than this, and they have flowered profusely enough. I have planted them out here in Lancashire, and they have been most satisfactory. In wet cold seasons they have been the reverse, and therefore I urged that system which had proved most reliable with me, and which I thought would be best for general practice. Since growing them in pots I have been compelled to remove them from the position in which they have been plunged outside to the protection of frames or a cool house. A few cold days or nights, especially if the weather is wet, soon starves them, the active fibres fail, and the wood of the plants hardens prematurely. The point upon which we mainly differ is about checking the

plants by lifting them. What I consider a serious check to the plants is evident that your correspondent does not. I may be a little too sensitive for their well-being, for I do not consider it is necessary that the plants should flag to arrive at the conclusion that they have been seriously checked.

It would interest me to know why your correspondent partially lifts them a fortnight or so before finally lifting them for potting. No doubt, any roots that are broken by this operation will have time to form fresh fibres nearer home. The plants are also practically brought to a standstill, and therefore less liable to suffer when lifted afterwards. What is this but a check to the plants? and if not, why take the precaution to soak them with water and syringe frequently to prevent flagging?

On page 131 "S. Y." takes exception to the soundness of a two-years system of raising these plants. I am not surprised, for at one time I should have questioned the wisdom of carrying out the practice I have advised. But circumstances alter cases, and experience has convinced me that a two-years system of raising plants would be much more suitable for the majority than raising the plants from either roots or cuttings, and have to depend upon producing good plants the same season. My advice, therefore, was intended for the many, not the few. In a large number of gardens where a great many plants have to be grown, and glass accommodation is limited, there is not the convenience either to propagate early or even to push the plants rapidly into growth. Many that are raised from roots in boxes are by the end of the season as strong as the pencil with which I am writing, and often 18 inches to 2 feet in length. These start strongly and even vigorously into growth, and if pushed on early are strong plants by the time cuttings are rooted. Time is not lost; on the contrary, two months are practically gained over raising plants from cuttings, unless the previous season is counted. At any rate, they are strong, with their first pots practically full of roots by the time cuttings are potted singly. For all with limited glass accommodation, small growers and amateurs, one-year-old Bouvardias to start with are the best. I have nothing to urge against raising the plants early and growing them in one year where there is convenience for early propagation and the accommodation of the plants afterwards.

The size of pot in which the plants are grown is not sufficiently reliable upon which to found any judgment either of the size of the plants or the manner in which they flower. It is not uncommon to see plants in $4\frac{1}{2}$ or 5-inch pots superior to others in pots 2 or 3 inches larger. I am no advocate for overpotting. The size of the pots in the case of the plants grown by "S. Y.," depends entirely upon keeping them under glass the whole season. With the size, "7 and 8-inch," that your correspondent advises, they might almost as well be placed out. Plants with almost unlimited root room are certain to make strong growth, though if placed outside, they would not fill the pots with roots or ripen sufficiently to flower profusely.

Pinching is practised a month later than I advise, and this is necessary where they are raised from cuttings and allowed to run up a foot or more before they are pinched. By the system of pinching I have advocated we have bushy examples by the time your correspondent has run up his plant high enough for pinching. "S. Y.'s" principle of culture is not new, two years ago plants were grown here exactly in the same way, but the object was different. I wanted strong plants for yielding strong roots in quantity for stock, not flowers. The plants were grown rapidly the whole season, and had they been given a light suitable position for solidifying their wood, they would have flowered profusely. But not one in a thousand have the convenience for encouraging the plants to make growth the same as our plants did that season. My advice, therefore, on page 12, was written for the guidance of the inexperienced and purposely to suit the greatest number of cultivators, to whom freeing their houses of the plants for two months or more during the season would prove an advantage.—WM. BARDNEY.

HORTICULTURAL BUILDINGS AND HEATING APPARATUS.

[A paper read by Mr. Henry Hope, horticultural builder, at a meeting of Birmingham Gardeners' Association.]

As the words "horticultural buildings" comprise a variety of structures which of necessity differ in form, size, and purpose, I propose to divide this portion of my paper into the following parts:—Conservatories (as exhibition buildings), fruit-growing houses, plant and flower houses, and propagating houses. But before entering into the detail of these different classes, I should like to treat upon the history of horticultural buildings and heating apparatus from the earliest records we have down to the present century.

HISTORY.

In looking back at the history of horticultural buildings it is not uninteresting to observe the progress of the industry of glass-making. The origin of glass is uncertain; it dates from a high antiquity. The Egyptians were acquainted with the substance 3500 years ago, and if we may trust the representations in Theban paintings glass vases were used for holding wine 1490 years before the Christian era. The glass of Egypt was generally opaque, specimens bearing the name of an

Egyptian queen of the year 1445 B.C. being in existence. After the Egyptians the Phœnicians were the most renowned for skill in this industry. The fact that at Nineveh, Herculaneum, and Pompeii specimens of glass of different kinds have been found is a conclusive proof that glass was pretty generally known to the ancients, and renders it almost an impossibility to ascribe the invention to any particular nation.

Early in the thirteenth century glass-making was practised by the Venetians, and from them it extended to Germany and France. The earliest manufacture of plate glass in England was begun in 1673, and from that date down to 1846 a duty was imposed on all glass made in this country. I will further on describe the different kinds of glass as now made and used.

The records of greenhouses before the eighteenth century are very meagre indeed, and I think only a few solitary cases of buildings erected for horticultural purposes are known. As lately as the commencement of the present century ponderous structures were erected by wealthy people having about the same proportion of glass in their construction as the Birmingham Town Hall, and indeed some of these have come under my notice being on a smaller scale, very much like this building, having a heavy cornice of classical design with a pediment front and lead roof with plaster ceiling, the light being admitted through windows in the sides, which were divided by brick or stone piers. These buildings were known as conservatories.

About the year 1700 greenhouses with brick sides and glass roofs, mostly of the "lean-to" pattern, were erected in gentlemen's gardens throughout England. These were mostly constructed of timber and glazed with crown glass in squares about 4 inches wide. A very expensive method of constructing greenhouses was adopted in some gardens. It consisted of mahogany framework cased in thin copper. This system soon proved to be as inefficient as it was expensive, as the wet got in between the metal casings and the wood, causing rot. Small-sized glass was used almost without exception down to the year 1846, when all duty on the article, both excise and customs, was abolished. A Birmingham manufacturer named Jordan was, to the best of my knowledge, the first person who made a business of horticultural building, and he was, in fact, the inventor of those metallic houses of iron framing and copper sashes. Messrs. Jones & Clarke were an offshoot of this business, which was eventually carried on under the style of Clarke & Hope. About the year 1820 metallic houses came into very general use. The best of these were constructed of framing and sashes, the framing being of cast iron and the sashes of wrought iron and copper. A less expensive method was to build them entirely of wrought iron, with ordinary section of T and L iron, the opening lights only being made as sashes. I do not think I need treat further of the history of horticultural buildings, as, although I am aware that I have only touched lightly upon this branch of the subject, time will not permit me to go further into it.

It is almost unnecessary to say that the methods of planning and erecting greenhouses has advanced in the last century with as rapid strides as any other trade to which English business men have devoted their attention, and whereas fifty years ago anyone wishing to build any garden houses would most probably have been compelled to plan them himself, and erect them by his own estate workmen, he can now command the services of at least a dozen first-class firms who make such work a speciality.

With regard to the heating of buildings by artificial means, I can only give the history comparatively small attention, as although the subject is a very large one, and open to much discussion, I think I cannot do better than confine myself to the methods that have been used, and are now in use, for the heating of horticultural buildings proper. The baths in the ancient Roman villas were, we know, heated by means of a circulating hot-water apparatus; thus even as far back as before the Christian era, the same principles were applied by which, at the present day, we carry out hot-water heating.

The first greenhouses that were built, about the year 1700, of which I have just spoken, were heated either by hot embers placed in holes in the floor and covered with a plate, or by brick flues, mostly the latter; and indeed this latter system has been used, more or less, down to about the year 1850.

The heating of greenhouses by hot-water apparatus was first adopted about the commencement of the present century, and most of these old apparatus that have come under my notice were constructed on much the same principles that are in vogue at the present time—viz, saddle form of boiler and large bore pipes, which is really what is now known as the low-pressure system, as opposed to the small-bore or high-pressure

system. The different kinds (some patent) of apparatus now manufactured by hundreds of firms, are innumerable; but as far as my knowledge goes, those who have been longest in the trade, and whose work has been pretty uniformly successful, nearly all strongly advocate the low pressure form of heating apparatus for horticultural buildings.

BOILERS.

I will now describe the component parts, and to commence with the boiler, I consider that a saddle form of boiler (either wrought or cast) set in brickwork, is very serviceable for horticultural purposes; for small ranges plain saddles, and for larger work terminal-end flued saddles. There are several patent boilers manufactured by different firms which answer their purpose exceedingly well, notably Weeks and Co.'s tubular boiler, which is composed of a ring of vertical tubes set in a fire-brick well and fed from the top; the larger ones are in two halves, and have water-way fire-bars. Messrs. Weeks have fixed these to work some exceedingly large apparatus, and from what I know of them they are very powerful boilers. Steam boilers and pipes were tried for large ranges of houses, but did not prove successful, as the heat from a steam pipe, being of a scorching quality, is not good for plant life. Some of these apparatus being put in by country firms gave a vast amount of trouble in the working, as steam traps were not brought to the perfection they are now, and consequently the condensed water collecting in the pipes stopped the heat, and in many cases split the pipes badly.

A great deal has been said about wrought versus cast boilers; the question really resolves itself into whether it is worth while, on account of the great durability of cast boilers, to run the risk of their liability to crack, as wrought boilers, although not so long lived, are not likely to crack, and consequently the latter have greatly superseded cast iron, as the cracking of a boiler may be of a very serious nature to the contents of the houses, especially if the accident occurs in frosty weather.

However good a boiler may be, good results cannot be obtained unless it is properly set and has a proportionately sized stack. The cause of many boilers not working properly is simply that the flues or the chimney are too small. The next portion of an apparatus which claims our attention is the main pipes. These should be of large bore; the old-fashioned method of putting small bore mains being a great mistake, throttling the circulation and putting much more strain upon the boiler than if the mains were large enough to allow the water to go ahead freely. Valves should always be pressure-tight and placed in both flow and return pipes to thoroughly stop the circulation. Air pipes are always preferable to air cocks, as being self-acting it is an impossibility for any air to collect in a properly constructed apparatus. The hot-water pipes should be placed on proper rollers, so to allow them to expand and contract freely.

BUILDINGS.

Having touched generally upon heating apparatus, I will now proceed to the different classes of horticultural buildings, together with the suitable interior fittings and heating appliances for each class. Commencing with conservatories as exhibition buildings, I can of course lay down no hard and fast line as to their construction, as individual circumstances always dictate their own conditions. As a general rule a conservatory is placed against the dwelling, with an entrance to it if possible from the drawing room. The design should always harmonise as much as possible with the architecture of the house, and a very good effect can generally be obtained without using unnecessarily heavy timbers, which is a very frequent fault in architectural conservatories. The sides of a conservatory should always if possible be twice as high as an ordinary plant house, and should be glazed with clear glass. Lead light work may in some designs be used in the transoms, but only very sparingly, and in any case only light twist. The glass in the roof of a conservatory should as a whole be either rough rolled plate or obscured sheet, as this will very often save the necessity of blinds.

Ample ventilation in the sides and roof should be provided, the lights to open simultaneously by a mechanical appliance. Shafting levers and screwgear are, I think, the safest and most easily worked of any that have come under my notice. The most convenient and general form for planning the interior of a conservatory is by placing staging for small plants about 2 to 3 feet on a level with the sill all round the glass front or sides, a border being placed against the back wall, and the wall and roof wired for creepers. The floor can either be laid all over with stone or tiles with the hot-water pipes in a trench all round, covered with cast-iron gratings, or a large bed or beds can be left in the middle for planting large Palms, &c. The quantity of hot-water pipes should never be overdone for a conservatory, as being only an exhibition house care

should be taken that it is a temperate one, the plants in bloom retaining their freshness much longer in a cool and well ventilated house than in a warm and stuffy one.

(To be continued.)

FRITILLARIA (KOROLKOWIA) SEWERZOWI.

THIS curious and interesting bulbous plant was first described in Regel's "Gartenflora," tab. 760, as *Korolkowia*, but was eventually reduced to *Fritillaria* by Mr. Baker in his revision of the *Liliaceæ*. In the figure referred to above the flowers are given as being very small, of a greenish yellow colour, and, as will be seen by our woodcut (fig. 33), some improvement in size at least has taken place since its introduction. The present species is extremely interesting, and is, moreover, a relief from the lurid tessellated forms so prevalent in collections. The habit also is most distinct, the bold glaucous foliage and yellowish green

FIG. 33.—FRITILLARIA (KOROLKOWIA) SEWERZOWI.

flowers being attractive in groups. The variety bicolor (*Gartenfl.*, 1181), called *discolor* in gardens, is a distinct improvement on the species, and well worth securing for collection. The whole plant is more robust, the flowers being considerably larger, bright yellowish green with a distinct reddish brown mark at the base. Both are quite hardy in English gardens, but usually flower too early. They should be planted in a dryish position in light sandy soil. Natives of Turkestan.

NOTES ON FRUIT TREES—APPLES.

(Continued from page 223.)

THE cultivation of Apples alike for home use and for market is of two kinds—viz., dwarfs, which comprise bush, pyramid, espalier, and cordon, horizontal, diagonal, or vertical methods of training; and large or standard systems. On the merits of the rival systems I do not intend to make any lengthy observations, but it is patent to all cultivators and observers that the finest fruit is produced by trees on the dwarf system, which is mostly, if not entirely, due to the favourable conditions of soil and location, to the greater pains taken in preparing the soil for the trees, and to the subsequent cultivation. Large or standard culture is of a most primeval character—viz., a hole is dug and a tree stuck in, and then it is left to Nature, no means being taken to increase its fertility or improve the quality of the fruit. I propose to make a selection from the varieties previously enumerated (which may not be the best, but I shall be happy to hear of better, and if objection is taken to any let it be stated on what ground), both for small or

large culture, or the dwarf or standard systems, and before proceeding it may be advisable to state that the deductions are taken from the actual performance of the trees, and the produce estimated by their seasonable value. To judge winter and spring Apples in autumn is not feasible, as it admits of no true estimate of their relative and special value, except of course from knowledge previously acquired. All, however, are not competent to reason from analogy, and the best test to which the generality of growers can put any subject is the practical, as it is by that tribunal the produce will be ultimately judged. The consumer has no "tender mercy" to bestow on an inferior variety and indifferent produce, and will pass sentence according to the relative utility of the product. What may suit the grower may not suit the customer; hence the latter's preference for the finer and sweeter American Apples, for as men advance in civilisation and wealth they lose their liking for crabs, and acquire a taste for the sweet refreshing juice of Apples.

My first point, therefore, is unprofitable fruit trees. Apples are grown unsuited to the taste and requirements of the consumer. True, well grown produce meet ready acceptance in the markets, but what is it in comparison to the general bulk of Apples marketed? The produce of trees grown in gardens on the dwarf or in orchards on standard trees where intelligent culture is practised may be profitable. What of the great number of trees that comprise the English orchards? Perhaps with an area ten times exceeding that of cultured fruit gardens and orchards not a tenth of their produce is fit to place in the markets. This, in part, from unsuitableness of variety, the clinging to kinds that may have been profitable in their day, but which from the increased inter-communication of growers adopting the better of the old and adding approved new varieties, have become obsolete and unprofitable. Perhaps nine-tenths of the varieties as grown in the gardens of cotters and in the orchards of farmers have, compared with imported produce, no value in the markets. It will bring a price no doubt, as there are those that must buy equally indigent with those that must sell at a price; but the placing of inferior produce in the market only assists the importer and consumer, as it causes the superior article to sell, not prejudicially affecting its price, whilst the inferior brings a poor price if it have not to be given away or disposed of at a sacrifice, so that if not an actual loss the labour of gathering, storing, and marketing is inadequately repaid.

The way out of the difficulty through the variety is to change. If the variety be good and pays leave it alone. Never mind about its name, although there is delight in knowledge, but stick to it as proved suited to the soil and situation, and one only to be displaced upon practical demonstration of other's superiority in all or a majority of points. Adopt some standard: there is no higher than that which commands the readiest sale and best price in the market, for there is seen the outcome of opposition and competition much more decisively and instructively than in exhibitions. In most cases it will be noticed that the varieties seen to the front are comparatively few. Growers that compete for prizes at exhibitions and those for market grow but few sorts; the first aims at excellence irrespective of crop, but the grower for market must have a combination of quality with quantity, therefore grows but few sorts, and those the most productive.

SELECTION OF VARIETIES FOR DESSERT OR KITCHEN.

Dwarf Culture or Trees on Paradise stocks—the Broad-leaved and Nonesuch being, perhaps, the best. These trees are very fibry rooted, and it is by the roots rather than the head that restriction of over-luxuriance and the inducing of a free-cropping habit is to be sought; indeed, pruning now must not be much practised if the trees are to pay, confining it to shortening the long shoots and thinning the others, so as to allow all parts of the trees to be fully exposed to the direct influence of the sun's rays and the action of the weather. Close by "cropped" or cut-in trees may afford a plentiful crop of blossom, but more frequently leaves. Something more is expected of fruit trees. To get the fruit the growth must be sturdy, thoroughly assimilating the aliment by exposure to light, air, and rain, and storing up food in the wood and buds in order to procure fruit when it is a matter of feeding in order to acquire the enviable position of pleasing everybody.

Pyramids.—Early: Lady Sudeley, Wormsley Pippin. Mid-season: King of the Pippins, Yorkshire Beauty, Lord Derby, King of Tomkins County. Late: Rhode Island Greening, Dutch Mignonne, Balchin's Pippin, Allen's Everlasting.

Bush.—Early: Duchess of Oldenburgh. Mid-season: Peasgood's Nonesuch, Baxter's Pearmain, American Mother, Fearn's Pippin, Hornead's Pearmain, Adam's Pearmain, Reinette de Canada. Large Bush: Cox's Pomona, Nelson Codlin, Harvey Apple, Gravenstein, Emperor Alexander. Small Bush: Small's Admirable. Late: Calville Malingre. It may be noted that Harvey Apple or Dr. Harvey is similar to, if not identical with, Golden Noble and Waltham Abbey Seedling, or if differing due in variation to soil

and location; also, Yorkshire Beauty is confounded with Red Hawthornden. The Yorkshire Beauty is the Greenup's Pippin of Dr. Hogg's "Fruit Manual," fourth edition, page 65 (I haven't the later or fifth edition), where it is very accurately described. It is also known as Cumberland Favourite, Palmer's Glory, and under other names. Adam's Pearmain blooming late escapes spring frosts when others suffer.

Cordons (horizontal, diagonal, or vertical on Paradise stock).—Lady Sudeley, Wormsley Pippin, Cobham, Peasgood's Nonesuch, Lord Derby, Dr. Hogg, King of the Pippins, Small's Admirable, Baxter's Pearmain, Reinette de Canada, Lane's Prince Albert, and Veitch's Sandringham. The last two, with Lord Derby and Dr. Hogg, also Peasgood's Nonesuch, may not please all tastes at dessert, but some relish a brisk acidity, and a large baked Apple, whilst everybody admires their noble appearance on occasion at table. Small's Admirable has a pleasing acidity. Dessert or kitchen.—Large culture or trees on Crab stocks, in which the pruning is confined to shortening or cutting out irregularities, and to thinning out the branches.

Espaliers.—Worcester Pearmain, Harvey Apple, Emperor Alexander, Baxter's Pearmain, Gravenstein, Harvey's Wiltshire Defiance, King of Tomkins County, Royal Pearmain, Rhode Island Greening, Dutch Mignonne, Stamford Pippin, and Allen's Everlasting.

Walls or Fences with east or west aspect, and all points between following the sun—i.e., from east to west. On a southern aspect (but only in the north, the south is too hot) the size, colour, and quality is superb.—Yorkshire Beauty or Greenup's Pippin, Washington, Northern Spy, Melon Apple, Melrose, The Queen, Sandringham, Dr. Hogg, Reinette de Canada, Lane's Prince Albert, King of Tomkins County, and Calville Malingre. If grown on low walls or fences the trees should be on the Paradise stock.

Standard.—Early: Lady Sudeley, Worcester Pearmain, Wormsley Pippin. Mid-season: Cox's Pomona, King of the Pippins, Emperor Alexander, Harvey Apple, Nelson Codlin, Melrose, Harvey's Wiltshire Defiance, Lady Henniker (which does not do on a wet heavy subsoil), Royal Pearmain, Baxter's Pearmain, Lewis's Incomparable, Hornead's Pearmain, Lemon Pippin, and King of Tomkins County. Late: Rhode Island Greening, Dutch Mignonne, Stamford Pippin, London Pippin, Allen's Everlasting, Hambledon Deux Ans, Barnack Beauty, and Balchin's Pearmain. Hambledon Deux Ans is not a great bearer in a young state, but not so great a sinner in that respect as Blenheim Pippin and Bess Pool, yet it (Hambledon Deux Ans) may not inaptly be taken for a green and late variety of Blenheim Pippin. Blenheim Pippin is a first-rate variety, the best of its season for either dessert or kitchen use from a marketing point of view, but those planting must wait at least a dozen years before the returns can be considered remunerative—in fact, it is a landlord's Apple. Bess Pool is a shy bearer when young, quite as bad as Blenheim Pippin, with the disadvantage that it does not bear the crops it might, and appears capable of doing when it attains its majority, otherwise they are varieties of unexceptionable value in their respective seasons, if indeed they have any equals. Regrafting, though tending to earlier cropping, is not so effective with these as with some other kinds, yet those who have kinds that are inferior through variety may with advantage be regrafted with Blenheim Pippin, and these will come into profitable bearing in about half the time that is required to obtain them by planting young trees, and singularly the fruit is finer and brighter in colour, but of this I shall treat in due course.

SELECTION OF DESSERT VARIETIES.

Dwarf Culture or Trees on Paradise Stocks.—*Pyramids*.—Early: Irish Peach, Kerry Pippin. Mid-season: King of the Pippins, Cox's Orange Pippin (does not succeed on cold wet subsoils), Fearn Pippin, Golden Reinette (requires a well drained soil), Claygate Pearmain (succeeds in heavy soil, where Ribston Pippin fails). Late: Rhode Island Greening, Court pendû Plat, Boston Russet, Allen's Everlasting.

Bush.—Duchess of Oldenburgh, American Mother, Adam's Pearmain, Mabbott's Pearmain, Margil, and Scarlet Nonpareil form highly prolific small bushes.

Cordons.—Horizontal, diagonal, or vertical: King of the Pippins, Cox's Orange Pippin, Fearn's Pippin, American Mother, Golden Reinette, Melon Apple, Claygate Pearmain, Margil, Court pendû Plat, Boston Russet, Scarlet Nonpareil, and to make up the dozen interlope Sturmer Pippin, which has been excluded through its being affected with a disease (fungoid) which is equally disastrous to flowers, foliage, and fruit.

LARGE CULTURE OR TREES ON CRAB STOCKS.

Espaliers.—Irish Peach, King of the Pippins, Cox's Orange Pippin, Fearn's Pippin, Adam's Pearmain, Golden Reinette, Clay-

gate Pearmain, Boston Russet, Mabbott's Pearmain, Rhode Island Greening, Court pendu Plat, Stamford Pippin, Allen's Everlasting. *Standards*.—Irish Peach, Kerry Pippin, King of the Pippins, Cox's Orange Pippin, Fearn's Pippin, American Mother, Golden Reinette, Court pendu Plat, Rhode Island Greening, Golden Russet, Stamford Pippin, Allen's Everlasting. Of the above Cox's Orange Pippin, American Mother, and Golden Reinette must have good well drained soil and warm situation. Golden Russet also prefers a light soil.

SELECTION OF KITCHEN VARIETIES.

Dwarf Culture or Trees on Paradise Stocks.—*Pyramids*.—Early: Keswick Codlin, Lord Suffield, Cellini. Midseason: Alfriston, Golden Noble, Grenadier, Yorkshire Beauty. Late: Dumelow's Seedling (cankers badly in heavy soil with a wet subsoil), Lane's Prince Albert, Gooseberry Apple.

Bush.—Early: Royal Codlin, Lord Grosvenor, Stirling Castle (a bad grower and scabby in many localities; Niton House is a larger fruit and better grower, but is a later and a better keeper). Midseason: Beauty of Kent (cankers on wet cold soils), Betty Geeson, Hollandbury, Lord Derby, Hornead Pearmain, Round Winter Nonesuch, Tower of Glamis, Warner's King, Emperor Alexander forms a large bush, and Small's Admirable a compact one. Late: Annie Elizabeth, Flanders Pippin, Lane's Prince Albert, Minchull Crab, Norfolk Beefing (does not succeed on a cold wet subsoil), Rymer. Cordons, horizontal, diagonal, or vertical: Lord Grosvenor, Lord Suffield, Potts' Seedling, Betty Geeson, Golden Noble, Grenadier, Peasgood's Nonesuch, Small's Admirable, Welford Park Nonesuch, Lord Derby, Round Winter Nonesuch, Lane's Prince Albert.—G. ABBEY.

(To be continued.)

EVENTS OF THE WEEK.—The March Spring Shows in the metropolis will be brought to a conclusion on Saturday, the 29th inst., by the Exhibition at the Crystal Palace, Sydenham, where an extensive display is expected. The Society meetings comprise the Royal Society on Thursday, March 27th, at 4.30 P.M., and the Quekett Club on Friday, March 28th, at 8 P.M.

— **THE WEATHER IN THE SOUTH** has been variable, with heavy rain and rather high winds on several days. Slight frosts have occurred in early morning, but the temperature has been generally fairly high for the season.

— **THE WEATHER IN SCOTLAND**, March 17th to 24th.—Last night 2° of frost were registered; on the morning of the 20th 2°. While the weather has been dull generally, one or two days have been partly or throughout very fine, yesterday (23rd) particularly so, the sunset being strikingly beautiful. The bloom of Crocuses has been extremely good, and is all but over. Other spring flowers are in grand bloom. The green tint is quite perceptible on the hedges in this part of S. Perthshire.—B. D.

— To an American journal Mr. George Nicholson, Curator of the Royal Gardens, Kew, has recently contributed a series of letters, entitled "HOLIDAY NOTES IN SOUTHERN FRANCE AND NORTHERN ITALY," in which he has given interesting descriptions of the gardens visited and the plants noted. In a recent letter he describes the Villa Thuret Garden at Antibes, which is under the management of M. Naulin, for experimental purposes in testing tropical and subtropical plants suitable for outdoor cultivation in France.

— **ROYAL BOTANIC SOCIETY OF LONDON.**—At a meeting of this Society, held on Saturday, Mr. G. J. Symons, F.R.S., in the chair, the donations reported included an interesting collection of seeds from the far-famed gardens of Mr. Thomas Hanbury at Mortola, on the coast near Ventimiglia, Italy, with printed catalogues of the great variety of plants and trees from all climes growing in the garden, more than four thousand named species.

— **THE BRITISH FRUIT GROWERS' ASSOCIATION.**—A meeting was held in the Town Hall, Ellesmere, Salop, on Saturday, March 22nd, at 7 P.M., by members of the above Association and the local society.

Brownlow R. O. Tower, Esq., occupied the chair and Mr. J. Wright delivered a lecture on Profitable Fruit Culture, which greatly interested a large audience. Several other members took part in the discussion which followed, and the meeting is pronounced to have been highly successful.—L. CASTLE, Hon. Sec.

— **THE LATE MR. JOHN WEBSTER.**—Will you permit an old reader of this Journal to say a few words about the above named well-known horticulturist? As probably some of your readers know he died early in the present month at the age of seventy-six, and had been in charge of the gardens at Gordon Castle for nearly forty years. He was born at Blannerne, in Berwickshire, December 8th, 1814, and commenced his gardening career at Manderston, and subsequently spent some time at Dalquharran Castle Gardens, at Whittinghame and Claremont. His first place as head gardener was at Earham, in Sussex, and thence proceeded to Gordon Castle in 1850, where he has remained ever since, and gained considerable reputation as a skilful practical gardener.—B.

— In addition to the above we have also to chronicle the recent deaths of DR. RALPH AINSWORTH of Manchester, in his 79th year, and MR. THOMAS HARRISON, Senr., of Leicester, head of the firm of Harrison & Sons, seedsmen, of that town.

— **UNDER** the title of the "JOURNAL DES ORCHIDÉES" M. Lucien Linden of Brussels has commenced a serial work on Orchids, which is to be published on the 1st and 15th of each month. The number before us comprises twenty pages of matter dealing with the history and culture of Orchids, by M. Rodigas; an article on white-flowered varieties of *Lælia anceps*, and several chapters on practical subjects. It is published at 100, Rue Belliard, Brussels.

— **CERTIFICATES FOR GARDENERS.**—When the proposed Hall of Horticulture is a reality and in working order I hope to see the examinations as formerly carried on by the R.H.S. again revived, so that young gardeners may be able to obtain certificates of their abilities. Why should not this be again taken in hand? It has a direct bearing on horticulture. Those who gain their certificates should afterwards, through the influence of the Society, be registered, and when in want of a situation be recommended by the Society, and due prominence given to the fact that the R.H.S. will recommend gardeners to those in want of them. As one who passed the examinations, and took first-class certificates in 1869, I venture to make the above suggestion.—H.

— **THE "CARTER" FAMILY OF CHRYSANTHEMUMS.**—In reference to the use and non-acknowledgment of one of our illustrations in a trade list, as mentioned on page 241 last week, Messrs. James Carter & Co. point to the fact that in the first edition of their list Mrs. Carter was included, and the illustration acknowledged; but the plants selling so rapidly compelled them to omit this variety from the second edition, and the removal of the type reference to our engraving, as applied to the other varieties, was purely accidental. The illustration equally well displays the character of these varieties, as the only difference between the trio is in their colours—one being described as straw, the other reddish brown and gold, the third pure white. The explanation is perfectly satisfactory, and we have no doubt these varieties, with their distinct thread-like florets, will find favour with many cultivators and floral decorators.

— **REGRAFTING ORCHARD TREES.**—I can fully endorse the remarks of "W. I.," page 236, on regrafting orchard trees, but where there are whole orchards of healthy trees I do not think gardeners want advice as to the merits of regrafting with superior varieties, as to that course they are fully alive. No doubt 90 per cent. of the fruit plantations which have been recently planted are where no other fruit trees previously existed. The system of grafting which "W. I." recommends is not by any means new. It is the general system adopted for many years by the farmers and cottagers of Worcestershire. I have been led to make these remarks in case readers of the Journal may think that the system recommended has only just been found out. It may be new to "W. I.," but to Worcestershire farmers and cottagers it is a very old practice, but nevertheless it is the best and quickest method.—A WORCESTERSHIRE MAN.

— **WE** have often referred to the value of COOL PLANT HOUSES, especially in the early spring months, as there are so many beautiful plants that in our uncertain climate are very liable to be damaged out of doors, though a little protection renders them quite safe. The cool house in the herbaceous department at Kew has been very gay for some weeks, and the following list of plants in flower will give an idea of what a varied display can be produced. *Drabas Mawi*, *lasiocarpa*, and

aizoides; Cyclamens Coum, ibericum, Atkinsi and repandum; Brodiaeas uniflora and porrifolia; Hepaticas triloba in variety and angulosa; Ranunculus anemonoides; Tulipa Kaufmanniana; Saxifragas Rocheliana coriophylla, Boydi, oppositifolia, oppositifolia alba, Rudolphiana, macropetala, luteo-purpurea, Malyi and imbricata; Primulas hirsuta, ciliata, denticulata, denticulata alba, Fortunei, Palinuri, marginata, obconica, floribunda, and pubescens alba; Chionodoxas cretensis, sardensis and gigantea; Crocus many species and varieties; Bulbocodiums in variety, Anemone apennina alba, Scillas taurica and campanulata, Iberis saxatilis and gihraltarica, Korolkowia Sewerzowi, Linum arboreum, Fritillaria tulipifolia, Hyacinthus azureus, Sisyrinchium grandiflorum, Daffodils in variety, Hellehorus orientalis, &c.

— GARDENING APPOINTMENT.—Mr. James Findlay, foreman, Castle Howard Gardens, has been appointed gardener to Sir Charles M. Palmer, Bart., M.P., Grinkle Park, Loftus-in-Cleveland, Yorks.

— MR. GEORGE PAUL writes—"MY BOG GARDEN has been a great success. I saw to-day in it most of the plants showing well, including Sarracenias, Orchis foliosa four or five sorts, double Marsh Marigolds, Primulas rosea and denticulata, Spiraeas, the larger American Cowslips, North American Lilies, and a nice hed of Cranberries, the big common kind."

— ON Tuesday evening, the 18th inst., there was a large attendance of members of the CROYDON GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT SOCIETY to hear a paper by Mr. Lewis Castle on "Hybridisation in Plants." Mr. C. S. Bowman occupied the chair. A thoroughly enjoyable evening was spent, and several members took part in the discussion which followed.—G. W. C.

— WINCHESTER HORTICULTURAL SOCIETY.—Preparations are being made for a Summer Show of more than ordinary magnitude in the ancient city, to open on July 8th. The schedule comprises forty-seven classes—namely, ten for plants, twenty-four for Roses, and the remainder for fruit, decorations, and vegetables. The chief prizes are £10, £7, and £4 for twelve specimen plants; £6, £4, and £2 for eight specimens; £4, £3, and £1 10s. for forty-eight Roses, with substantial amounts in various other classes. Mr. Chaloner Shenton is the Honorary Secretary.

— THE WEATHER IN THE NORTH has been unfavourable for sowing seeds. No sowing of any kind on farms has taken place yet, but the early seedtime does not always bring the earliest and best harvest. In 1827, the year following the "short corn year," the memorable 3rd of March a heavy fall of snow took place, and another on the 23rd April, which lay till the 15th of May, being the first day seed was sown, while much snow was about. Yet that was one of the most hounteous seasons and early harvests on record. It is not the continuation of wintry weather that causes late and poor harvests, but fine weather early in the year succeeded by extreme cold in May and June.—W. T., Lanarkshire.

— THE CARDIFF CHRYSANTHEMUM SOCIETY.—The annual meeting of this Society was held at the Black Lion Hotel, Cardiff, on Friday evening, March 21st, a large number of members being present. The Secretary reported that the Society was in a flourishing condition, the balance in hand being £59 19s. 10d. The following were elected officers for the ensuing year:—President, the Marquis of Bute; Hon. Sec., Mr. C. R. Waldron; Assistant Secretary, Mr. F. Searl; the old Committee was re-elected, with Mr. T. Malpass Chairman and Mr. A. Bishop Vice-Chairman. It was resolved that the Society be affiliated with the National Chrysanthemum Society, and decided to hold the next Show on November 18th and 19th, 1890.

— NATIONAL CHRYSANTHEMUM SOCIETY.—May I invite the co-operation of Chrysanthemum growers in the efforts that are now being made by the Special Committee of the National Chrysanthemum Society—viz., Mr. Lewis Castle, Hotham House, Merton, Surrey; Mr. George Gordon, 1, Stile Villas, Wellesley Road, Gunnersbury; and Mr. C. Harman Payne (Hon. Sec.), 60, Thorne Road, London, S.W., in the preparation of an entirely new edition of the N.C.S. Catalogue? The National Chrysanthemum Society have good reason to be satisfied with their last publication in 1888, both as regards the acknowledged advantages of its classification and other general information, and also the sale, which has considerably more than balanced the cost incurred; but it is desired that this new edition should be even more improved, while several fresh features will be added. With this end in view I venture to ask for space for this note, in the hope that many who are interested in the work of the N.C.S. will lend us their assistance by offering sug-

gestions, and specially by affording any information as to synonyms or errors, either of omission or commission, in the previous editions. Such information will be welcomed by either of the gentlemen forming the Committee.—WILLIAM HOLMES, *Frampton Park Nurseries, Hackney, London.*

— BIRMINGHAM GARDENERS' ASSOCIATION.—At the fortnightly meeting of the Association, March 18th, Mr. W. Stevens, The Gardens, Walton Grange, Stone, read a paper on "Odontoglossums, Varieties and Cultivation," and contributed cut specimens of Odontoglossums Cervantesi, Andersoni, gloriosum, luteo-purpurea, Alexandrae, Rossi, &c. It appeared to be a very interesting well thought out paper, and short-cultural remarks with each of the various species of Odontoglossums were given. In reply to questions as to fumigating Orchids, Mr. Stevens did not particularly recommend smoking unless with dry tobacco paper, and then not if they had been shut up in a close house for a week or more. He recommended for thrips the application of a little dry sulphur with a camel's-hair pencil as a cure, and in dividing Orchids to smear the cut in the rhizome with dry charcoal dust to prevent bleeding. Much very useful information was given as to the best method of ventilation for Orchids, shading for cool Orchids, and the best materials. Amongst the latter, an application in very hot weather of flour and cold water, not too thick, and put on when the glass is dry, was recommended. Mr. Powell, gardener to G. H. Kenrick, Esq., exhibited a plant in bloom of Dendrobium endocharis, one of Messrs. Veitch and Sons' hybrids, and the result of a cross between aureum and moniliforme; also a fine plant of D. Devonianum, imported in February 1887, with seven leading growths 4 feet long, with fifty-seven expanded blooms upon it. Mr. Powell also sent a bloom of Amaryllis Favorite (Veitch), a flower rich in colour and grand in form.

— PRESTON SPRING SHOW.—The Show, which was held on the 19th and 20th insts., was the best spring display that has been seen at Preston. Every class was well represented, but the principal feature of the Exhibition was a magnificent bank of Orchids and Ferns set up by Mr. George Beddoe, gardener to E. G. Wrigley, Esq., Howick House, Preston. Too much praise could not be given to this excellent display. The plants in this exhibit covered a space not less than 70 feet by 12 feet, the whole length of the orchestra. In previous years this space has been admirably filled by Mr. Troughton of Preston with a choice miscellaneous bank. The groups arranged for effect by nurserymen and gentlemen's gardeners were never better. The specimen stove and other plants were also excellent examples of high-class culture, Mr. Frisby of Worden Hall being the principal prizewinner in these classes. Mr. J. B. Dixon, however, ran him pretty close in a few of the leading classes. Mr. Lamh's table plants were admired by all. Hyacinths and other bulbs were better than in some seasons. Primulas were very fine indeed. The second prizetaker for the group of Orchids, Mr. Chas. Baker, exhibited most creditably, and when we consider his display is the outcome of leisure hour culture, it speaks well for the great attention he must devote to them. He has been an exhibitor of Orchids in keen competition for many years. Mr. Payne of Fulwood was the most successful exhibitor in the nurserymen's classes, and his Azaleas have been for many years the admiration of all.—A. W.

LANDSCAPE GARDENING.

[Read at a meeting of the Cardiff Gardeners' Association by Mr. Kettlewell.]

(Continued from page 239.)

ROCKERIES.

THERE are few gardens that do not possess a rockery, and I would venture to say that some of them are out of place. If there happens to be a vacant shady place in a garden, that is at once a suitable position for a rockery. The distinguishing element of all rockeries should be rusticity. No fused bricks or scoriae should be used in its construction, as is often seen in town gardens, but the materials and stones used should be of a conspicuously natural character, and should never lie with their ends or points placed upwards, but flat, thus giving an appearance of solidity and strength which is only in accordance with what Nature teaches us. The surface of the whole cannot be too irregular or indented, and is in the gradual dying away, so to speak, of rockery with a few loose masses of stone scattered here and there, rather than in an abrupt ending, that the skill and observation of a landscape gardener come into play. In a rockery Ferns are an essential requisite, and to grow Ferns well shade is necessary; but if a rockery be accompanied by a small pool of water having a rugged margin, gold fish to

add a little life and movement to the picturesqueness may be kept, and some of the rarer kinds of aquatic plants grown; besides this the moisture arising from such a sheet of water would be very beneficial to many rock plants. Among the shrubs suitable for a rockery may be mentioned most shrubs with trailing habit, such as Ivy, *Cotoneaster microphylla*, *Periwinkles*, some kinds of *Berberis*; climbers also, such as *Clematis*, *Virginian Creeper*, and the better sorts of *Brambles*, if they are carefully pruned so as not to stifle the smaller plants and Ferns, are pleasing adjuncts to the bolder parts, while varieties of the green-leaved *Holly*, *Arbutus*, and *Junipers*, will be ornamental evergreens to give colouring to the scene.

PARKS AND LODGES.

The last special department on which I should like to write a few words is that of parks and lodges. Much greater care and attention is required to effectively form and plant a park well than to design a garden, inasmuch as the trees and materials with which one works are on a bolder and grander scale. If, then, the clumps or plantations are injudiciously placed or are too numerous they look blotchy and become offensive to the eye. If there are too many specimens scattered about the whole looks "spotty" and contrary to Nature. On the other hand, if the clumps are too narrow and thin and the specimens too few there is a bareness and baldness, which is as faulty and out of character as over-planting. The glades of a park should be broad and undulating, the plantations at their margin bold and rich in clothing. Specimen trees should chiefly be attached to those clumps which stand alone in a glade, in order that it may have an appearance of continuity, and not seem to end too abruptly and artificially. A park should not be considered as an isolated factor in a design, but must be in unison with the other parts, and represent an intermediate link between the dressed portions of a garden and the wilder, freer, and bolder characteristics of Nature.

In close proximity to the garden the ground should have a certain degree of smoothness and ease, the clumps richer than the outside boundaries, thus assisting a gradual and almost imperceptible transition between the wilder features of Nature and the more polished scenery of the garden.

A few words as to the trees most serviceable for park planting. For specimen trees nothing will surpass some of the *Abies*, especially the *Abies Douglasi*. *Quercus Ilex*, *Cedar of Lebanon*, *Red-flowering Horse Chestnut*, *Cedrus Deodara*, *Taxodium distichum*, *Purple Beech*, *Elms*, *English Oak*, *Scarlet Oak*, and *Sycamore* are also useful in this respect. Very showy shrubs or trees are, however, inadmissible in a park, as they interrupt the gradual transition from Art to Nature. The commoner kinds of *Thorn*, *Holly*, *Yew*, *Box*; in chalky districts the common *Juniper*, *Furze*, *Broom*, and *Privet*, *Berberis aquifolium*, are among the most useful for planting in the clumps. To these may be added the common *Oak*, *Elm*, *Beech*, *Hazel*, *Mountain Ash*, common *Whitebeam*, *Spruces*, *Scotch Fir*, *Austrian Pine*, and many others.

Lodges should never be seen from the house, and therefore are seldom needed in a demesne of limited extent, as the drive to the mansion should be long enough to hide the lodge from view. The lodge should be placed on the side which has the best view of the road and drive, and for that reason the inner side of the curve would be most suitable supposing that the drive curves at all. A few flowers and shrubs would be an appropriate accompaniment to a lodge, as they give the dwelling a pleasant, bright appearance. A bank of shrubs and trees around to screen it, with a few specimens at the margin, also gives the dwelling a park-like appearance, and prevents the building being staring and out of character with its surroundings.

PRACTICAL TREATMENT.

It is with a few suggestions on the practical treatment of a garden that I purpose bringing to an end this paper on the art of landscape gardening. First of all, with reference to the outline of work in laying out grounds, it is essential if land of any extent is to be laid out, whether it be a public park, cemetery, or garden, that a definite plan of arrangement on a sufficiently large scale be first decided upon, as it is much easier to judge the proportions of the various parts of a design on a plane surface, such as paper, than on the natural surface of the ground. Sections where the ground is very uneven should then be drawn out from levels previously taken, the vertical scale being double the horizontal scale for the sake of distinctness. Tracings of all should then be given to the foreman to guide him in his work. When this has been done, the next thing is to set out the walks, plantations, and beds by actual measurement from the plan, in order that you may obtain the same easiness of lines and curves, and the accurate distribution of the various parts.

Then the actual work begins, and the soil and turf should be stripped off and taken away from the spot which the house will cover, and at least from 25 to 30 feet all round, in order that space may be given to the builders and workmen, and room for depositing rubbish, from the foundations. The main drive to the house should then be at once commenced, the soil taken out to the depth of about 18 inches, the drain laid, and the drive filled up to within about 3 inches of the surface with flints, coarse gravel, rubble, or any angular material that will remain dry and porous; lastly, the whole must be well beaten to make the various materials set well.

The reasons for forming the main drive first are obvious—namely, to prevent workmen employed in building the house from making footpaths and roads over all parts of the ground, and to give a means of access to the house for carts. The boundary fence should then be the next consideration, as it affords privacy to the place and prevents people trampling over any portion of the ground. The walls of the kitchen garden must be built as soon as possible, in order to get the bricklayers out of the way before anything is done in the way of trenching or levelling. In the meantime any rough work can be done, such as draining, forming mounds, sheets of water, or rockeries, so as to gradually work the surface of the ground into the proper shape and outlines.

By this time the house will no doubt be nearly finished as far as the building is concerned, so that the edgings of the walks can be formed, planting begun, as it is much better to plant before the turf is laid down, in order that the grass may not be soiled or trampled; the ground may be levelled and the turf laid.

When the grass has settled and the workmen have left the house, the verges can be accurately cut, the gravel on the walks and drives laid down, and the whole completed. If, however, any workmen, such as plasterers, painters, or carpenters doing outside work to the house have not finished, it is better to defer the planting, levelling, and turfing immediately around the house, as the turf and shrubs may get trampled on and even destroyed. I have now given a rough and cursory sketch of the routine of work in laying out a garden, I will give a few suggestions on the practical treatment of walks, drains, and planting.

(To be continued.)

TREDEGAR PARK.

SITUATED between two of the busiest ports of South Wales, Cardiff, and Newport, and only two miles distant from the latter, bounded by a network of railways that are continually busy bearing their freights of coal and other minerals for sea transit, and the hosts of passengers that are always on the wing between South Wales and the outside world bent upon matters of commerce, &c. Here, within a somewhat extensive and well-furnished park, stands the above mansion, the beautiful home of generations of the Morgan family. The family, now represented by the Right Hon. Lord Tredegar, have been connected with the county history of both Brecon and Monmouth for upwards of 250 years, both counties being repeatedly represented in Parliament by them. The mansion was built early in the seventeenth century, and an idea of its importance will be gained from the fact that its architect was no other than the famous Inigo Jones, the style of which will be seen by the accompanying illustration. The present Lord Tredegar is known as one of the heroes of the "Charge of the Light Brigade," serving as Captain in the 17th Lancers, then the Hon. Geoffrey Morgan. He rode through *Balaclava*, *Alma*, and *Inkerman*, and escaped with his famous charger "Sir Briggs" to well-earned retirement at Tredegar. "Sir Briggs" has since had honourable burial in the grounds, with a monument bearing a suitable inscription to his memory marking the spot. May his noble rider long survive him. As patrons of agriculture and horticulture the family have been long and widely known. The annual fat stock show bearing his lordship's name is among the first of its kind; but our interest is chiefly with the latter pursuit, and therefore must chronicle our impressions from the horticulturist's standpoint. First of all our attention is directed to a group of trees in the flower garden that appear somewhat out of place. There are some very fine *Larches*, *Cedar of Lebanon*, *Catalpa*, *Cork Tree*, and *Red Wood*, with specimens of *Silver Elms* at a short distance off, about 60 feet high. These specimens are respectively among the earliest introductions of their kinds to this country, after hearing which we feel far from begrudging them their places. There are also in the vicinity some fine specimens of *Tulip Tree*, and *Sweet Bays* are perfectly at home, several specimens over 30 feet high. Enumerating trees reminds us of another somewhat rare specimen in a moist position adjoining the kitchen garden—namely, the *Liquidamber*, 35 feet high. Immediately fronting the mansion there are also some fine specimens of *Variegated Hollies* and *Araucarias*, as shown in fig. 34; and bordering an ornamental lake, which supplies water to the mansion, are magnificent deciduous trees in variety, bearing evidences of many storms in the long past, but well calculated to brave the fury of many more. A young pinetum in miniature near by contained some excellent *Wellingtonias*, running a very even race of

rivalry, and on a bank in close proximity was a hedge of Laurels, where our worthy guide (Mr. Rhoderick) pointed out the superiority of the variety *rotundifolia* over the old common Laurel, the colour and texture of the leaf being much better, and the wood hardier and more retentive of the lower foliage.

A glance at the massive iron gates in the illustration will convey a better idea of their style than will a written description. Suffice it to say that they are very old, and are all the best class of handwork. A large square or court in approaching the mansion is skirted with wide borders which are ribboned in the season in the old style with spring and summer bedding plants and bulbs in their respective seasons, and an inner square is also done in a similar manner, both being rendered most attractively gay. Walls surrounding the flower garden are in part clothed with Roses, Clematis, Jasmines, and a host of useful flowering climbers, and partly with Plums and other fruit trees, the wide borders in the former instance being furnished with a useful collection of herbaceous plants and bulbs, which, supplemented by other similar

succession, so that masses of colour and variety can always be relied upon to create an effective display at all seasons in the splendid apartments, which have always to be kept brilliantly gay. The ordinary pip-mountaining would not do here, nothing less than branches of flowers would have any effect in some of the larger receptacles. That Mr. Rhoderick should be able to keep up such a supply with somewhat limited means, for the houses are not of modern build, speaks well for the system that he practises. Some of the principal flowers used are *Richardia aethiopica*, grown outdoors in summer in trenches, hundreds of them. *Chrysanthemums*—upwards of a thousand plants of the best varieties are grown, besides large quantities grown and flowered in sheltered positions. In this collection we saw the most perfect form of *Mrs. Alpheus Hardy*—a lovely flower.

Poinsettias, large quantities bearing bracts 15 inches across, with late struck plants ranging from 6 to 18 inches high, very useful for bordering, &c.; hybrid *Rhododendrons*, and *Azaleas mollis*, *indica*, and other varieties, are forced by the score, whilst of *Roman Hyacinths* no

FIG. 34.—TREDEGAR HOUSE.

borders in various positions in the garden, afford a valuable supplementary supply of cut flowers to those artificially produced. High and dense Yew and Bay hedges afford shelter to many tender plants. In one enclosure of these Azaleas and Camellias luxuriate, and we remember a splendid bed of *Lilium auratum* here in all its known glory. On the high walls of the mansion and buildings on this side are splendid examples of *Magnolia grandiflora*. One of these measures 35 to 40 feet high, and about the same in breadth. A miniature flower garden near Mr. Rhoderick's house is also a pretty picture. Small beds in a box design, always gay with summer and winter occupants alternately facing a rustic summer house, overhung with Clematis, *Wistaria sinensis*, &c., in common with adjoining walls. The usual bedding, which is most extensively done, but not on the rigid lines common in modern gardening, must for the present be passed over with the bare remark that it takes the best part of several houses throughout the winter to store and nurse the many thousands of plants required for this purpose, the same houses being devoted afterwards to the culture of Melons, Cucumbers, and Tomatoes. In the glass department we find that Mr. Rhoderick works on a splendid system in catering for the huge demand for furnishing material in the way of plants and cut flowers. Immense supplies of everything suitable for cutting purposes are brought on in

less than 10,000 are annually forced, and about as many other *Hyacinths* and *Tulips*. Mr. Rhoderick speaks highly of *Scilla campanulata alba* for pot work, but it should not be forced too hard. *Bouvardias* and *Solanums* in early winter are found valuable, whilst double and semi-double *Geraniums* are indispensable. Double *Primulas* and *Cyclamens* are strongly in evidence, and the much-talked-of *Kalanchoe carnea*, has obtained a favourable verdict.

Of plants for house work, Mr. Rhoderick speaks well of the variegated *Indiarubber*, *Ficus elastica variegata*, and *Dracena Lindenii*, as two valuable additions to ornamental plants for this purpose; the latter has had a bad name for losing its colour in the lower leaves, but this is perhaps on account of keeping too far from the light when growing, and in too strong heat. The *Kentias* and *Areca lutescens* in Palms are favourites, though many others are grown, with *Crotons* and *Dracenas* as reinforcements. About 1400 *Violets* in frames, several varieties vieing with each other for first place, the chief varieties being *Marie Louise*, *New York*, and *Comte de Brazza*. *Roses* should have been mentioned as one of the principal plants in the above list. The best *Teas* and *H.P.'s* are worked in succession, to which might be added large borders throughout the kitchen garden and elsewhere that furnish abundance of the coveted blooms. The usual fruit and vegetable forcing

is not neglected either, for the more poetic part of gardening. Indeed the demand in these, particularly the latter department, seems to be as great as for flowers, and is as well supplied, judging from the vast and choice stocks that are always to be seen in the kitchen garden. Grapes, Peaches, Figs—"the latter do well outdoors, and of which there are some fine specimens"—have their share of attention, and, in common with other parts of his charge, testify to the untiring energy and ability of the unostentatious gardener, Mr. Rhoderick, who is, by-the-by, a worthy pupil of Mr. David Thomson of Drumlanrig.—BRADWEN.

THE VALUE OF CALANTHES.

I WAS pleased to see, on page 200, Mr. Iggulden could speak so highly of the utility of the *Calanthe* flowers when cut; and I can corroborate his assertion that *Calanthes* stand pre-eminent in many positions. One of the most effective displays I have seen was that in which *C. Veitchi* and *C. vestita* were freely employed in a group of miscellaneous plants at a *Chrysanthemum* show. But as I had promised to write a few lines on the cultivation of the *Calanthe* as practised here (before I saw Mr. Iggulden's article), and as he speaks of a suspended shelf, I will begin with the supposition that the pots containing the pseudo-bulbs of *C. Veitchi*, *C. vestita*, *C. lutea* are now stored away high and dry on a suspended shelf, for in such a place they are always kept when at rest here, free from an accidental watering and in a temperature about 60°. Previous to potting I think it a good plan to start the pseudo-bulbs in the following way. After cleaning and trimming all the old roots off I set them in a box with about 1 inch of fine sifted leaves and sand, well mixed, spread evenly on the bottom of the box, arranging them according to size at the same time. The boxes are then placed back on the shelf in the stove for about two weeks, or until the young roots are 1 inch long; then they are finally potted in 32 and 48-size pots, which we find quite large enough. Three of the largest pseudo-bulbs of *C. vestita* and four to five of the smaller are placed into a 32-sized pot. The largest pseudo-bulbs of *C. Veitchi* we place into 48-size singly, that being a convenient size to drop in amongst Ferns and other foliage plants when in flower.

The compost used is one-third each of good Orchid peat broken up with the hand, all fine particles being shaken out; one-third dried cow manure, fresh horse droppings as prepared for Mushroom, small charcoal, coarse silver sand, and leaves through a quarter-inch sieve. All these are well mixed together and warmed. The pots are well drained, but not excessively so. Just the same as a 48 or 32-pot would be drained for a *Chrysanthemum*, using the roughest part of the compost in the bottoms of the pots. Press the soil moderately firm with the hand, fill up to about 1 inch from the top, arrange the pseudo-bulbs that the young growths will have plenty of room, covering the young root with the fine part of the soil. The pseudo-bulbs are in no case raised above the rim of the pots, as I have seen them potted many times. With a gentle watering they are returned to head-quarters, the suspended shelf in the stove being carefully watered until the roots run freely, when they receive copious supplies of liquid manure prepared from fresh horse droppings and soot, which seems to give the desired result—viz., a grand display of flower spikes.—J. C. H.

SEASONABLE TREATMENT OF ONCIDIUMS.

ALL *Oncidiums* that are growing with the *Cattleyas* may be top-dressed, except those that it is necessary to place into larger pots, pans, or baskets. These plants are less difficult to pot than *Cattleyas*, for their roots are not so easily destroyed. Many *Oncidiums* will flourish in the same basket for years provided they are top-dressed with moss and peat annually. When these plants are placed in baskets plenty of charcoal should be given them, and their roots will soon become attached to it; the compost used for them should be near the surface, so that it can be removed when decomposed. It is sometimes difficult to pick out the whole, but it can generally be washed out, and when this is done the baskets must be allowed to drain thoroughly before the new compost is applied. Those in pots or pans that need a larger size should have them most liberally drained, for these plants root most freely upon the surface. The majority do well in peat fibre and a little charcoal intermixed, with a good layer of moss on the surface. When repotting any plants decomposed soil should be removed and the

roots washed clean in tepid water. If the material used for potting is good, and too large shifts are not given, they will be in sweet condition in the space of two years, when they should require larger pots or pans. More water may now be given to the roots of those starting, while those repotted must be watered very carefully until they are growing and rooting freely. If these or any Orchids are overwatered after they have been repotted they are certain to suffer, but with care they will start freely and vigorously into growth. For the present make no attempt to grow the sphagnum on the surface of these plants; they can be surfaced after they have commenced growing freely, and then the moss can be encouraged.—B.

ROYAL HORTICULTURAL SOCIETY.

MARCH 25TH.

AS at the previous meeting in the Drill Hall, James Street, Westminster, the exhibits on Tuesday were both numerous and interesting in a more than ordinary degree. Nearly the whole of the available space was occupied, Hyacinths, Daffodils, spring flowers, Roses, Orchids, and Cinerarias forming the leading attractions in the floral department, the Fruit Committee's business being necessarily more restricted, though several important features were provided.

There was a large attendance of Fellows and visitors during the afternoon, when M. Henry de Vilmorin of Paris delivered an able lecture upon "Salading," briefly noted at the end of this report. The meeting altogether was highly satisfactory and creditable to the Society.

FRUIT COMMITTEE.—Present—Sir C. W. Strickland, Bart. (in the chair), with Mons. Henry de Vilmorin, Dr. Hogg, and Messrs. P. Crowley, R. D. Blackmore, Harrison Weir, J. Cheal, C. Ross, G. W. Cummins, J. Smith, J. Willard, W. Warren, H. J. Pearson, G. Wythes, J. Hudson, F. Q. Lane, G. Bunyard, A. W. Sutton, A. Watkins, and J. Wright.

Mr. Lockie sent fruits of Lockie's Perfection Cucumber, a short-necked good variety, for which a vote of thanks was recorded. Mr. J. Smith, Mentmore, was accorded a similar mark of approval for a brace of Cucumbers in excellent condition. Mr. F. Q. Lane sent samples of different forms of Watercress, showing slight variations in colour and form of leaf. They were from cultivated beds in Hertfordshire, and it was stated that the varieties did not thrive equally well in the same part of the stream. Mr. Willard remarked that the Brown Cress turned green when grown at Highgate, and Mr. Wright said Watercress was very delicate and tender grown from seed or cuttings in rich moist soil in frames in early spring. Mr. W. C. Leach, Albury Park Gardens, sent several heads of Veitch's Standard Bearer Celery, as a good late variety continuing in use till May. The Celery was clear, firm, crisp, and of good quality. A vote of thanks was accorded.

Mr. J. Simms, gardener to W. Eastwood, Esq., Kingswood, Englefield Green, sent very fine and well coloured fruits of *La Grosse Sucrée* Strawberry, for which a cultural commendation was unanimously granted. Mr. W. Roupell sent a small collection of Apples grown within five miles of Charing Cross. Annie Elizabeth was particularly firm and fine; Striped Beefing also very fine; the Melon Apple and Bismarck having lost their freshness. The two Apples first mentioned must be regarded as among the best of late keeping varieties, and such samples as those in question would sell readily at good prices at this period of the year, excelling as they did the best of the American produce now in the market. Mr. W. Lewis, South Leasons, Malvern, sent a dish of a seedling Apple, medium sized, Pearmain shaped, recommended by the exhibitor for late eating and cooking. It was not considered quite good enough for dessert nor large enough for culinary purposes, hence no award was made. Mr. C. Ross, Welford, sent a seedling Apple of unknown parentage named Armorer, small, flattish fruit, firm and sweet. An award of merit was recommended, further experience being required to justify the award of a first class certificate. Mr. C. Lyc sent a seedling Apple which was passed, as also was Ashford Seedling, that was before the Committee on a former occasion.

A collection of salads was sent by Mr. James Webber, including excellent Lettuces, Endive, Radishes, Chicory, Witloof, Cucumbers, Beet and different varieties of Cress, for which a vote of thanks was unanimously granted.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair, and Messrs. R. Dean, A. Truffaut, G. Paul, H. Herbst, B. Wynne, T. Baines, C. T. Druery, C. Jefferies, J. Walker, F. Ross, Harry Turner, W. C. Leach, R. B. Lowe, J. Fraser, H. Cannell, W. Holmes, Lewis Castle, and the Rev. H. H. Dombrain.

The most extensive and handsome group of plants came from Messrs. B. S. Williams & Son, Upper Holloway, for which the Committee unanimously recommended a silver-gilt medal. The chief feature in this was formed by about a hundred even and admirable Hyacinths of the best varieties, and bearing massive spikes of varied colours. *Clivias*, another of the Holloway specialties, were equally fine, their bold rich green leaves and great trusses of flowers having a striking effect, such varieties as Baron Schröder, Martha Reimers, cruenta, and Meteor being conspicuous. Guelder Roses and dwarf Lilacs in pots were very notable for their compact habit and large numbers of flower trusses. Lilies of the Valley were well represented, as also was the fragrant *Boronia megastigma*. The whole of one side of a table extending the length of the Hall was devoted to this group, and even then room could not be found for all the plants.

Messrs. Paul & Son, Cheshunt, contributed a bright and pleasing group of Roses in pots (silver medal), comprising plants of the graceful Polyantha varieties, Mignonette and the new Clothilde Soupert, with the large single variety grandiflora. Of other varieties the new H.P. Lady Alice, The Puritan, Jean Ducher, Souvenir de S. A. Prince and Madame Hoste were admirably represented.

Mr. James of Farnham Royal had his usual handsome Cinerarias, the flowers of great size, and the colours remarkably rich (silver medal). Messrs. Barr & Son, King Street, Covent Garden, showed a large collection of Daffodils, including representatives of the chief varieties now in favour; the brilliant Anemone fulgens and the blue Chinodoxas also furnished much colour (silver medal). From Messrs. Cutbush & Son, Highgate, came a group of Epacris in many varieties (bronze medal); and Messrs. H. Cannell & Sons, Swanley, had some excellent double Cinerarias and single Zonal Pelargoniums (bronze medal). Mr. C. Turner, Slough, showed some boxes of Carnation blooms (vote of thanks). Messrs. J. Veitch & Sons, Chelsea, had several new Hyacinths; and Mr. R. Dean contributed a collection of Primroses (vote of thanks).

The amateurs' exhibits were not numerous. Mr. J. H. Froud, gardener to J. W. Ford, Esq., Chase Park, Enfield, sent specimens of Acacia retinodes with long pale yellow spikes of sweet scented flowers and a collection of Camellia flowers (vote of thanks). Mr. G. W. Cummins, gardener to A. H. Smee, Esq., Carshalton, showed strong plants of Veltheimia viridifolia, having long spikes of pinkish flowers and well developed shining green leaves, and Mr. J. Gregory, Haselbeck Hall Gardens, Northampton, sent flowering stems of the yellow Celsia cretica (vote of thanks).

A basket of Alpine and other plants from the Royal Gardens, Kew, contained several Anemones, one of the most noteworthy being A. apennina alba with pure white flowers. Good varieties of Saxifraga oppositifolia were also shown, together with some of the earlier flowering Primulas.

ORCHID COMMITTEE.—Present: Sir Trevor Lawrence, Bart., M.P., in the chair, and Messrs. S. Courtauld, T. B. Haywood, H. M. Pollett, F. Dominy, H. Ballantine, C. Pilcher, E. Hill, H. Williams, Lewis Castle, F. Moore, F. G. Tautz, A. H. Smee, J. O'Brien, and Dr. M. T. Masters.

Orchids were not quite so strongly represented as at the last two meetings, but several interesting plants were shown, and the Committee had a full share of work. Messrs. Sander & Co., St. Albans, had a small group of Orchids, including Oncidium bifolium majus, a vigorous plant, bearing six panicles of flowers, and growing in a basket. Oncidium tetrapetalum is one of the small flowered species, with a roundish white lip and brown spotted sepals and petals. Angrecum Germinyanum has a white heart-shaped lip, prolonged at the apex into a linear tail. The sepals and petals are long, narrow, recurving, and white. It is of slender graceful growth. Dendrobium nobile nobilius was well represented, the flowers deeply coloured, and Odontoglossum vexillarium, St. Albans type, distinguished by the deep colour of the flowers.

N. C. Cookson, Esq., Wylam-on-Tyne, again showed a plant of the hybrid Phaius Cooksoni, the lip being of a much deeper and richer colour than when it was seen at the last meeting. R. Young, Esq., Liverpool, showed a small flowered unattractive Cypripedium named C. hybridum Poyntzianum. Messrs. Hugh Low & Co., Clapton, had a fine Phalenopsis which they termed Schilleriano-gloriosa, on the assumption that it was intermediate between the forms expressed in the name. F. G. Tautz, Esq., Studley House, Hammersmith (gardener, Mr. Cowley), had plants of Cattleya Trianae Tautziana, a fine well-coloured variety (award of merit), the distinct Dendrobium chrysodiscus, D. Freemani, Lycaste cruenta, and the charming little Odontoglossum blandum.

A remarkable Orchid was sent from the Royal Gardens, Kew—namely, Coelogyne pandurata, which has green sepals and petals, the lip being also green but heavily marked in the centre with black, an uncommon combination of tints, both green and black, but especially the latter being rare in flowers. A. H. Smee, Esq., sent two plants of Cyrtopodium Saintlegerianum, so strong and evidently well grown that a cultural commendation was accorded for them. One of the plants was named superbum, a distinct and superior variety to the other, the flowers large and the colouring much richer. Baron Schröder, The Dell, Egham, exhibited a plant of Odontoglossum Leeanaum, with yellow flowers thickly dotted with brown, one of the best of its type. Cattleya Trianae Schroederiana alba had pure white sepals and petals, the lip yellow in the centre. H. F. Nalder, Esq., Mornington Lodge, West Kensington (gardener, Mr. T. W. Rogers), showed a highly coloured variety of Dendrobium nobile, and Messrs. Pitcher & Manda, Swanley, sent a small group of Cypripediums and Cattleyas. E. Ellis, Esq., Manor House, Warrington (gardener, Mr. T. A. Glover), sent a variety of Odontoglossum Andersonianum named Ellisi, Lycaste Schilleriana with greenish flowers, and Dendrobium nobile.

Angrecum citratum was shown by W. F. Darnall, Esq., Devonshire House, Stamford Hill (gardener, Mr. G. Elliott); a healthy plant in a small basket, and bearing four long racemes of its creamy flowers (cultural commendation). W. C. Walter, Esq., Piercy Lodge, Winchmore Hill (gardener, Mr. G. Cragg), had a plant of Oncidium sarcodes having two panicles each 6 or 7 feet long (cultural commendation).

PLANTS CERTIFICATED.

Dendrobium Wardianum, Baron Schröder's variety (Baron Schröder).—An exceedingly attractive and distinct variety, having very large flowers, the sepals and petals tipped with deep rich crimson, the sepals flushed with a light shade of the same colour, the petals ivory or creamy

white. The lip is broad, with maroon blotches at the base, then a rich yellow zone, white and tipped crimson. A first-class certificate was unanimously granted for this superb variety.

Lælio-Cattleya Hippolyta (J. Veitch & Sons).—A remarkable hybrid between Cattleya Mossiae and Lælia cinnabarina, and presenting a combination of the characters in the two parents. The sepals are narrow and spreading, the petals broader in the centre and more lanceolate in shape; the lip was narrow, and not fully open. The colour is a peculiar shade of orange buff, of uniform depth throughout except at the apex of the lip, where it is faintly flushed with crimson, and at the base of the sepals and petals a darker shade of the same colour is noticed (first-class certificate).

Philadelphus inodorus (Mr. W. C. Leach, Albury Park Gardens).—A Mock Orange or Syringa, wanting the fragrance that distinguishes some of the species. The flowers are large, pure white, freely produced, and last well when cut. Mr. Leach finds it a useful shrub for forcing, and when potted early it can be had in flower at Christmas (award of merit).

Deutzia candidissima flore pleno (Mr. W. C. Leach).—Another free and useful shrub, bearing its neat double starry pure white flowers in long racemes. The leaves are elliptical in form and neatly serrated at the edge.

Iris sindjarensis (Messrs. Barr & Son).—A dwarf species with short, broad, somewhat glaucous recurving leaves, the flowers pale lavender blue, the falls lighter in the centre (award of merit).

Trillium discolor atratum (J. Veitch & Sons).—A variety with extremely dark claret purple flowers and spotted leaves.

Lily of the Valley, Fortin's variety (Mr. E. Morse, Epsom).—Several varieties of Lily of the Valley are now in cultivation, and that above named is distinguished by the size of the flowers and the general strong habit of the foliage and growth.

THE LECTURE.

A general meeting was held at 3 P.M., in the Drill Hall, Dr. Robert Hogg in the chair. After the election of a number of Fellows the Chairman introduced M. Henry de Vilmorin of Paris, who had been announced to deliver a lecture on "Salad Plants," and he was heartily received by the exceptionally large audience. The lecturer commenced his remarks by referring to the necessity of vegetable food in addition to meat for constituting a diet calculated to promote health. Most salad plants, he observed, in common with many other plants, contain salts of potash, which are largely removed from ordinary vegetables in the process of boiling, but are retained in salads, as they are used in an uncooked state. This important point he impressed upon his audience as one of the strongest recommendations of salads. The various parts of plants specially employed for salad purposes were next briefly reviewed—the roots, as in Beet; bulbs, as in Onions and their relatives; stems and leaves, as in Chicory; leaves, as in Lettuces, Endive, and Dandelion; flowers, as in Tropæolum and Borage; and fruits, as in the Tomato and Cucumber.

M. de Vilmorin then divided the remaining portion of his subject under two heads—first, a list of vegetables suitable for salads, and second, the methods and importance of blanching as applied to plants employed in this manner. He remarked that the Continental idea of salads was slightly different from that prevailing in England, as they were often regarded as constituting separate dishes, and not merely as accompaniments to richer viands, though some were almost invariably employed in the latter way, others in the former. The names and qualities of the principal kinds used in Paris, and the times during which they were obtainable in the markets, were next briefly given, and the lecturer proceeded to a consideration of blanching. He said it was generally understood that the flavours and green colour of plants were chiefly developed under the influence of light and heat. The exclusion of light, or blanching, consequently renders them not only white but milder in flavour where this is naturally strong, as in Celery, Dandelions, and other plants. Many native plants might no doubt be improved or rendered suitable for food in some form by this process; and M. Vilmorin stated that a list had been prepared of over 200 plants, native to France, which it had been thought could be utilised in this way. He then proceeded to deal at some length with the culture and blanching of Witloof, Barbe du Capucine, Dandelion, and other plants employed in France, and concluded an able lecture by thanking his auditors for their attention.

Dr. R. Hogg proposed a vote of thanks to M. de Vilmorin, and remarked that they were greatly indebted to him for his interesting discourse. Dr. M. T. Masters seconded the proposition, it was heartily supported, and carried by acclamation. M. de Vilmorin replied in a few grateful sentences, and the meeting terminated.

GARDENERS IN WANT OF SITUATIONS AND THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

I HAVE been much interested in the discussions of late in the *Journal of Horticulture* relative to gardeners obtaining situations when unfortunately they happen to be "out." The matter was carefully discussed at the last Committee meeting of the above Society, and it was resolved to invite the opinions of its members on the subject. As a benefit and provident society registered under the Friendly Society Acts, we cannot divert any of our funds to assist gardeners in other

than sickness and old age, and that to members only. I believe, however, that means will be devised eventually whereby it may be so arranged that by a separate subscription and distinct management, yet identified with the Society, members may have their names entered in a register when in need of a situation. Thus, when it becomes better known that the Society recommends gardeners to ladies and gentlemen in want of them, we hope to benefit our members. In all future printing of balance-sheets and circulars, we propose to insert the information that we recommend our members who may be out of place to the favourable notice of proprietors. I might state that we already help each other all we can in this respect. Two cases in point have occurred since our last meeting, and one just previously, in which one member obtained a situation for another. Other cases might be quoted, but this is sufficient to show that, as a body of fellow gardeners banded together in a society, "benefit and provident," we do assist each other, and endeavour to carry out our motto, "Union is strength." I hope after our next meeting to be able to give more definite information on the subject.—TREASURER.

ROSE SHOW FIXTURES 1890.

- June 24th.—Drill Hall, Westminster (N.R.S.).
 „ 27th.—Royal Aquarium.
 „ 28th.—Eltham, Reigate.
 July 1st.—Canterbury, Hereford, Sutton.
 „ 2nd.—Croydon, Dursley, Hitchin.
 „ 3rd.—Bath, Farningham, Norwich.
 „ 5th.—Crystal Palace (N.R.S.).
 „ 8th.—Gloucester, Ipswich, Winchester.
 „ 9th.—Diss, Ealing, Tunbridge Wells.
 „ 10th.—Birkenhead, Worksop.
 „ 17th.—Birmingham (N.R.S.), Helensburgh.
 „ 22nd.—Tilshelf.

The only Rose Show on the above list which extends over more than one day is that at Winchester, which will be held on the 8th and 9th of July.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

MARÉCHAL NIEL ROSE IN VINERY.

WE have here a Maréchal Niel in the early vinery, from which we have cut this year fourteen dozen blooms. The house is a lean-to, and the back wall is 13 feet high. The Rose is planted out at one end, going up with a couple of clear stems to a height of about 9 feet. The growths are then tied to wires run along the wall, the lowest of which is about 4 feet from the top of the house, so that even when the Vines are in full foliage they have a fair amount of light. Green fly appears at times, but a good washing by means of a garden engine soon rids the plants of the pest.—J. M. N. ASTON.

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY

(Continued from page 246.)

Madame Falcot (Guillot, 1858).—Of good growth and foliage, not liable to mildew, or very much hurt by rain. A huttonhole Rose, rather small, and loose, thin, and wanting in centre when expanded. It is somewhat of the same type as Safrano, of deeper and brighter colour, and altogether better in bloom, but less hardy, of less vigorous growth, and not quite so free flowering. Rather tender for a huttonhole Rose, which we generally expect, I do not know why, to be more vigorous and hardy than show varieties; but a lovely bud, the exterior of the outer petals having often the most charming combinations of red and yellow, and the whole flower being sometimes of a beautiful deep self-yellow. It is a good autumnal, but does not seem to answer thoroughly well as a dwarf.

Madame Hippolyte Jamain (Guillot, 1869).—Of good growth, strong enough for a low wall, which suits it well; not much liable to mildew, and bearing rain better than some. The flower stalks are pliable, and the blooms, which come late and generally well, though occasionally divided, are completely pendent. This is one of those Roses whose beauty is quite concealed on the plant, and few who have only seen it as growing would believe what a beautiful flower it is when properly shown at the right stage. At this period the outer petals fall well down when the bloom is held up, and display a charmingly tinted and shaped centre. Afterwards, in very hot weather or on a wall, it expands to quite a flat shape with a much yellower colour, and many would not recognise it as the same Rose; but it may be thoroughly depended on to last when cut in the right condition, for it requires fine, hot weather to open at all. It does well as a dwarf, but best on a wall facing east or west, and will then be found not too early for exhibitions; is only fair as a free bloomer, requires too much heat to be a good autumnal; and is not of a large size, but the spread of the fine lower petals makes this and Roses of similar shape appear to the utmost

advantage, and larger than they really are. Note that there is a light coloured H.P. of the same name as this Rose.

Madame Hoste (Guillot, 1887).—Too new an acquaintance to speak of without any certainty, but it seems promising, with fair stiff growth and good foliage; very good shape, but not very stout in petals; free blooming and of good size. It is not a useful colour, for we want something more deep and decided among yellow show Tea Roses.

Madame Lambard (Lacharme, 1877).—Of good healthy growth with fair foliage, rather liable to mildew, but being a thin Rose is a good deal less subject to injury from rain than other Teas. The blooms come generally well, but the strongest ones are sometimes divided; they are thin in petal, not very large, and wanting in fulness; must be grown very strong to be shown well, and then are not lasting. A cool season Rose, very free blooming, but to the ordinary grower of little account in the summer when other Teas which can stand the hot sun are to be had. In the late autumn Madame Lambard is a friend indeed. I had nearly as many blooms of it in the open in the middle of last November as I could gather from all my other Roses put together. It does well as a dwarf, and is remarkable for its extreme variation in colour; you may have some blooms of a bright light red, others of salmon, and others of rosy buff or lighter, all on a plant at the same time.

Madame Margottin (Guillot, 1866).—Of fine sturdy growth, with good foliage. Does well as a dwarf, and is not liable to mildew, but is very easily spoiled by rain, as this is a Rose of the opposite extreme to the one last mentioned. It is very full, with thick petals, refusing to open properly except in hot dry weather, and consequently, though free of bloom, is generally of no use as an autumnal. The strongest blooms some malformed sometimes, and indeed a perfect one is not very easy to get, but a great acquisition when it does come, as it has good size, fine globular shape, bright colour, and first-class lasting qualities.

Madame Welche (Ducher, 1878).—Moderate in growth and in quality throughout. Not a free bloomer, rather deficient in size, and not of the best shape; but the colour is distinct and good, the centre being sometimes very nearly orange.

Madame Willermoz (Lacharme, 1845).—Of very sturdy stout growth, with splendid foliage, not liable to mildew, but very easily injured by rain. This is an old Rose, and still of considerable repute, though no favourite of mine. I find it full of abundant promise in its exuberant growth and foliage, but generally sadly lacking in the production of handsomely shaped useful blooms when the critical time comes. The petals are very fine, but the form is not good, the outside petals keeping up as tight to the bloom as possible, and a well defined point in the centre being often absent. This is the worst shape for exhibition, as it makes the bloom appear smaller than it really is, and a strong temptation arises to "dress," or rather "undress," Madame Willermoz by bending down the outside petals. The effect is very great, for not only does it make the bloom rather more of the shape which rosarians approve of, and the size appear considerably larger, but also the inside of the outer petals is naturally of a much purer and cleaner white than the outside; and thus, by this simple process, the Rose appears larger, better shape, and purer in colour. It is, however, distinctly "altering the character" of the Rose, and the N.R.S. appears to be right in setting its face against the presentation of any Rose in a shape which it never naturally assumes. It does well as a dwarf, the stiff upright character of the wood being well suited to this modern mode of culture. The blooms sometimes come divided, and it cannot be called a free bloomer or a good autumnal.

Marie Van Houtte (Ducher, 1871).—The strongest and best in growth of any of the pure Teas, with fine evergreen foliage, very little liable to mildew, and not much injured by rain. The blooms come generally well, but occasionally divided. A cooler time after hot weather, which is most favourable for all Roses, will show Marie Van Houtte at its best. In manners and customs and all-round good qualities it must take first prize among the Teas; at all times a beautiful bloom, in perfection most lovely, excellent in petal, fulness, shape, colour, lasting qualities and size, very free in bloom, and a good autumnal. It does perfectly well as a dwarf, is not particular as to soil, and is undoubtedly the one Tea Rose no one should be without.

Niphetos (Bougère 1844) is a good instance of what is called "free" growth—i.e., neither long nor stout, but branching and generally growing somewhere. The foliage is good and not much liable to mildew, but the blooms will not stand rain. A Rose of great reputation for its free flowering qualities and the purity of its white colour. It is likely, I suppose, that Mons. Bougère, the raiser, is not now alive. I do not know how many thousand feet run of glass houses are maintained for the purpose of growing the Rose which he appropriately named Niphetos (Snowy), but I apprehend the figures would very much have astonished him could he have known them when he issued it, and he would perhaps have wished to attach his own name to it, instead of to the much less valuable production of twelve years before. White flowers are always in especial demand, not only because they are lovely in themselves, do not lose their colour and go well with everything, but also because on the three great occasions of birth, marriage and death they are generally considered to be of the most, if not of the only, appropriate colour. It so happens that Niphetos, the purest of all white Roses, has a long bud especially suitable for bouquets and wreaths, is free flowering and bears forcing well; it is no wonder, therefore, that it is cultivated for market purposes to an astonishing extent. But it is also capable of being exhibited as a Rose of great merit, with very fine petals and of the largest size. I have never seen better specimens than

those exhibited by some of the leading amateurs at the last National Rose Society's show at the Crystal Palace. The blooms come well, though occasionally divided, but they must be cut young for show (when there is often a greenish lemon tinge in the strong buds which is very becoming), as the shape is not lasting, and when the outside petals do come down they fall completely, giving the idea of a total collapse. It is free blooming throughout the season, but the autumnal buds will not come large, and require fine weather. This well known Rose does much best as a standard. I can get no show blooms from dwarfs, and the wood being neither stiff nor upright the petals get much injured by wind and rain unless the flowers are held well up above the ground.

A climbing sport of *Niphetos* has been issued this year, which gives a promise of being exceedingly valuable for the production of cut buds of this ever useful sort.—W. R. RAILLEM.

(To be continued.)

THE BATH FLORAL FÊTE.

THE spring Show provided by the Committee of the above took place in the Assembly Rooms on the 19th inst., and proved to be remarkably good all round, and it was regarded as one of the best Exhibitions ever held in Bath. Spring flowering bulbs, such as Hyacinths, Tulips, Narcissi, Crocus, &c., were a good feature. The best eighteen Hyacinths came from Messrs. R. T. Veitch & Son of Exeter, a well-grown and bloomed collection. Mr. G. Garraway, Bailbrook, was a good second. The best twelve in pairs of six varieties came from Mr. Garraway; Mr. Davis, gardener to Dr. S. P. Budd of Bath, was second. In the class for twelve distinct varieties shown by amateurs, Dr. Budd was first, and Mr. Marsh, gardener to J. M. Dunlop, Esq., Bristol, second. Dr. Budd was also first with a very good half dozen; Mr. G. White, gardener to J. Watts, Esq., Bristol, was second. The same exhibitors were successful with Tulips.

Daffodils were a good feature, there being a class for twelve pots. Mr. E. Kerslake, gardener to the Rev. E. Handley, Bath, won first prize with well-flowered examples of such sorts as Emperor, Empress, Countess of Annesley, Horsfield, Sir Watkin, Golden Spur, &c. Dr. Budd was second with good flowers also. The Rev. E. Handley offered special prizes for a group of Daffodils shown in pots or boxes tastefully arranged in pots, and took the first prize. Messrs. R. T. Veitch & Sons were second with a more representative collection, but not so well arranged. Some fine pots of *Lily of the Valley* were shown by Dr. Budd. *Amaryllises* were well grown and flowered, but they consisted of old-fashioned types with pointed petals. The best three came from Mr. A. Hawkins, gardener to Mrs. Jolley, Bath.

Orchids made an excellent feature, and, as usual, the Rev. E. Handley was first with fine examples of *Dendrobium nobile*, *D. nobile pendulum*, *Cymbidium Lowianum*, *Odontoglossum triumphans*, *O. Edwardi*, and *Cattleya Trianae* Leana, he being the only exhibitor in this class. The best three came from Mr. R. B. Cator of Bath, who had capital specimens of *Cypripedium villosum*, *Dendrobium Wardianum*, and *Cattleya Trianae*. Mr. A. Taylor was second with *Phaenopsis Schilleriana*, *Dendrobium crepidatum*, and *Dendrochilum glumaceum* insigne. The best specimen Orchid was *Cattleya Trianae* from the Rev. E. Handley; Mr. Howell, gardener to J. T. Holmes, Esq., Bath, being second with *Cœlogyne cristata*. A remarkably interesting collection of plants, Orchids predominating, was set up by Mr. J. Cypher, nurseryman, Cheltenham.

Groups of plants arranged for effect were placed on tables, and they had a charming appearance. In the open class Messrs. Geo. Cooling and Sons were first, Ferns, Orchids, Acers and other foliage and flowering plants being tastefully displayed. In the amateurs' class Mr. R. B. Cator was first with a charming group also, Mr. J. T. Tate, gardener to W. Pumphrey, Esq., Bath, being second. Cut flowers comprised boxes of twelve Roses, Dr. Budd being first with an excellent dozen, and Mr. R. B. Cator second. In the classes for a hand bouquet, buttonhole bouquets, ladies' sprays, and a vase or epergne, Mr. C. Winstone won all the first prizes in a most worthy manner.

Fruit was confined to Apples and Pears. Mr. S. King had a very fine dish of Cornish Gilliflower, and Mr. R. H. Taylor a capital dish of well preserved Beurré Rance Pears. Vegetables were shown well for the season of the year. The best collection of six varieties came from Mr. W. Evry, Bath.

First-class certificates of merit were awarded to Mr. Cypher for *Odontoglossum baphicanthum superbum*, *Dendrobium nobile* *Cyprianum*, a very fine pale form, and to *Phaius tuberculosus*.

BULB SHOW AT HAARLEM.

FEW British horticulturists need to be told that Haarlem, in Holland, is the centre of the great trade in what are known as Dutch bulbs. In and around that town are cultivated the millions of Hyacinths, Tulips, Crocuses, and other bulbs which are distributed by seedsmen and nurserymen in this country in autumn. It might naturally be supposed that in the home of the bulb, interest in its culture would be of so great a nature as to culminate at times in a grand display of bulbous flowers. That is so, but either from excess of native modesty or of business cares the growers only indulge themselves in a large show once in every five years. These Exhibitions are organised by the Dutch

Bulb Growers' Union, and the fourth of them was held at Haarlem on March 21st, 22nd, 23rd, 24th, and 25th of the present year. Perhaps it will not be without interest to endeavour to give bulb cultivators in this country some idea of what their brethren in Holland, who are experts in bulb culture, are capable of effecting when they turn once in a while from the commercial to the decorative aspect of the bulb industry, and endeavour to excel each other in the quality of the flowers for exhibition, as they do in the ordinary course in the quality of bulbs for sale.

A general comparison between a Dutch and an English bulb show could hardly be made, nor would it be strictly fair to attempt it when it is considered how different the conditions are. In the former case bulb specialists select the best roots from the enormous stocks at their command, and devote to them all the knowledge and care that the experience of generations has supplied them with. In the latter ordinary bulbs, limited in number, without special treatment, have to be relied upon. Nevertheless, the result of a comparison would not be discouraging to British growers. Visitors to the Show of the present year would see a magnificent Exhibition in every way, one worthy even of so long a journey, but not overwhelmingly superior in some respects.

It is doubtful if better Hyacinths were ever exhibited than those shown at Haarlem this year. It is in these flowers that the interest of the Dutch growers, and of the general public also, largely centres. This is hardly the case in England. In Holland, Hyacinths; in England, Daffodils—that is the position of the two countries as regards spring bulbous flowers; small wonder, therefore, that both exhibitors and visitors should view the Exhibition, mainly composed as it was of the former flowers in the very best condition, with pride and satisfaction. Without doubt they were a magnificent display, several of the most famous growers in Holland showing in better form than at any previous exhibition. Tulips were bright and beautiful, but not perhaps of such exceptional quality as the Hyacinths. They were hardly dwarf enough to be perfect, and the flowers were not above the average size. Narcissi, as has been before hinted, do not command the same attention in Holland as in England. There were none of the grand collections seen at the London spring shows, and here was a great point of difference; still there was some material on which the Daffodil lover could feast.

The arrangements of the Dutch shows differ materially from those in vogue here. All the exhibits have to be sent in two days before the Show opens. On the intervening day the Jury make their awards, and then arrange the plants to give the best general effect, not grouping them in the order of the schedule. This deliberation serves its purpose, and is possible in a quinquennial show, but we have not time for it here with our numerous annual displays. The Committee, with Mr. J. H. Krcilage, President of the Union, at its head, worked most energetically in the arrangement of the Show, and great credit is due to them for the successful issue to which it was carried. The representative of the *Journal of Horticulture* was enabled to pursue his duties in connection with the Exhibition under the most favourable and convenient conditions, thanks, in a great measure, to the courteous assistance of Mr. G. H. van Waveren, an active member of the Committee.

And now a few remarks as to the special features of the Show.

HYACINTHS.

As before stated, the display of these was very large and fine. In the first class, four groups of 100 distinct varieties, all fine spikes, produced, as would be imagined, a very beautiful effect. Two of the most famous Hyacinth growers in Holland, the Brothers Byvoet of Overveen, near Haarlem, and Messrs. J. H. Kersten of Haarlem, between whom the struggle for supremacy is always close and keen, were in competition, and other noted cultivators had also entered. Between the first two, as on the occasion of the last Show five years ago, the issue lay, but history failed to repeat itself, Messrs. Byvoet turning the tables on their former conquerors. More interesting to British bulb growers, perhaps, than the names of the exhibitors, which are in most cases unfamiliar to them, though not to tradesmen, will be the names of some of the varieties which represented them, and some idea of their quality. Some of the best varieties are comparatively unknown to cultivators in England; on the other hand, many of the varieties best known to us were also used extensively. In the class under notice, for instance, the splendid gold medal group of Byvoet Brothers included such familiar Hyacinths as *Gigantea*, *La Tour d'Auvergne*, *Couronne de Celle*, *Fabiola*, *So faterre*, *Pieneman*, *Marie*, *Von Schiller*, *King of the Blues*, *Noble par Mérite*, *Czar Peter*, *Madame Hodgson*, *Gertrude*, *Lady Derby*, *Snowball*, and *La Grandesse*. These are known to almost every British bulb grower, but somewhat less familiar are *Queen of the Blues*, a magnificent pale blue; *Roi des Belges*, rich sparkling crimson; *Veronica*, bright red; *Cardinal Wiseman*, pink, very large bells; *Thackeray*, deep bronzy purple, small spike but very distinct in colour; *Leviathan*, white with faint rosy tinge, very close truss, a beautiful variety; *Princess Amalia*, blush, very large bells; *Menotti*, rich red; and *Moreno*, pale rose. These are all charming varieties, worth adding to any collection. Messrs. Kersten & Co., who raise a very large number of seedlings, had numerous unfamiliar varieties, amongst them Dr. Windthorst, white, large, substantial bells, good spike; *Miss le Jeune*, mauve; *Tolstoi*, blush, double; *La Nuit*, black; *Blush Perfection*, beautiful semi-double; *Snowflake*, pure white; *Duke of Albany*, very fine double red; *Jacques*, blush, enormous truss, but somewhat loose; *The First*, double, soft rose; *Grand Concomant*, double, blush; and some good unnamed varieties. Mr. T. van der Horst of Noordwijk had a fine collection, including *L'Ornement Rose*, blush, with waxy substantial petals; *The Sultan*, shining purple; *George Peabody*, somewhat small spike, but bells of enormous size and substance,

"Cambridge" blue; Victor Emmanuel, bright rose; Montagne Bernard, crimson; and Anna, ivory white. As regards quality, these would bear close scrutiny. In nearly every case the plants were dwarf, the spikes rising well from the foliage and furnished with large substantial bells.

In the class for forty distinct varieties Mr. van der Horst was first with a magnificent group, including a truss of the blush coloured variety Jacques, 10 inches long by $4\frac{1}{2}$ inches in diameter; one of Pieneman, but a shade smaller, a splendid example of the popular blue Czar Peter, and also a very fine truss of La Grandesse, such as is rarely seen in England. Messrs. Byvoet were a good second and Messrs. Kersten and Co. third. Another important class for Hyacinths, and in which the Dutch growers took a great deal of interest, was that for seventy-five spikes in twenty-five varieties, each to be confined to one stem. This produced some splendid examples of culture, and collectively they were a rich display. Messrs. Kersten & Co. were placed first, Messrs. Byvoet Brothers second, and Messrs. M. van Waveren & Son third. There were not many points between the two first named. Messrs. Kersten had grand examples of the fine dark variety King of the Blues, the spikes densely clothed; of Financier, a splendid light blue; of L'Innocence, a beautiful pure white; of the pink Fabiola; of King of the Reds, bright red; and of Charles Dickens, delicate pink. Messrs. Byvoet had three splendid trusses of Von Schiller, one of the best reds in cultivation; of Baron von Tuyl, dark blue; of Cardinal Wiseman, pink; of King of the Blues; of L'Incomparable, deep crimson, and of Lord Macaulay, bright red, after the style of Von Schiller. Messrs. van Waveren's flowers were smaller but in very good condition.

It will suffice to deal briefly with the smaller classes for Hyacinths, as it would be tedious to give details of them all. Mr. van der Horst had a very good collection of twenty single varieties, and was placed first, winning also with twelve doubles. Messrs. Byvoet won with twenty-five doubles, a very fine collection. Double Hyacinths are not often shown so well as in this case. Noble par Mérite, pink, was one of the best; and Koh-i-noor, bright red, semi-double, was also good. The best blues were Louis Philippe, Blocksberg, Charles Dickens, and Van Speyk. Amongst the whites Duchesse de Bedford, Miss Nightingale, very beautiful, pure white, and Anna Bianca were amongst the best. In the best examples the spikes were comparatively compact, but in this respect they suffer, of course, by contrast with the singles. Mr. G. Blokhuis had a splendid group of fifty singles and doubles mixed, though not including any very sensational spikes. They were a remarkably even and well grown group of plants, very dwarf. The redoubtable Byvoet Brothers had here to take second place. In the other classes for Hyacinths in pots there was little to call for comment except the splendid collections of twenty-four doubles in eight varieties shown by Messrs. Byvoet and Kersten, which were wonderfully good, but as they were not confined to a single stem it would be useless to give the measurements of the trusses.

The Hyacinths in pans were highly effective. Several classes were devoted to them. In most part the varieties were such favourites as Gigantea, King of the Blues, La Grandesse, Von Schiller, Pieneman, Czar Peter, Masterpiece, Baroness van Tuyl, and Latour d'Auvergne. In each pan were ten spikes, all well grown in nearly every case. Mr. J. B. Bos of Overveen, Mr. P. Louwerse of Schoten, and Messrs. E. H. Krelage & Son of Haarlem were the prizewinners.

The Hyacinths in glasses were very little inferior to those in pots, although less numerous. Nearly all were in what are known as Tye's glasses, and all of which were plain "window glass," none coloured. The first prize for sixty examples went to Mr. A. J. Blom of Overveen, who had a very fine collection; Von Schiller (8 inches by 4), Lord Derby, pale blue; King of the Blues; Fabiola, pink; Mr. Plimsoll, pure white; Marie, dark blue; and Lord Macaulay, bright red, of proportionate quality, speak well for the success of this method of treatment as practised by our Dutch friends. The doubles were particularly fine, far better, in fact, than when grown in pots, the spikes being much more closely furnished. A very fine collection from Mr. G. Van der Mei would probably have secured the first prize, but for an accidental transgression of the rules, which led to its disqualification. Messrs. P. van Velsen & Sons of Overveen and G. van Velsen of Haarlem also had some good flowers.

TULIPS.

While the Hyacinths were of exceptional quality the Tulips appeared to be nearer the average of former years. Messrs. L. van Waveren & Co. of Hillegom were first with 100 varieties, single and double, a neat fresh collection, but with somewhat small flowers. Such well-known varieties as Rose Gris-de-lin, Proserpine, rich rose; Vermilion Brilliant, scarlet; Artus, scarlet; and Silver Standard, crimson flaked with white, were good. Less known, but in most cases better varieties, were Roi Pépin, white flaked; Murillo, delicate blush, double; Mon Trésor, splendid rich yellow; Nelly, pure white, very large flower; Le Grandeur, crimson; Rachel Ruisch, white, tinted rose; and Adeline, rose. Messrs. M. van Waveren & Son were second in this class. Messrs. F. & H. van Waveren, Hillegom, won with thirty varieties; a very fine collection; Bride of Haarlem, flaked; Chrysolora, yellow; Joost van Vondel, red variety; Proserpine, rose; and Artus, scarlet; being all very good indeed. Messrs. F. & H. van Waveren also won with fifty varieties, amongst the best pots being Yellow Prince, L'Immaculée, white; Ophir d'Or, beautiful yellow; Joost van Vondel, white; Silver Standard, Baechus, rich crimson; La Précieuse, beautiful pink; and Golden Standard. Messrs. L. van Waveren & Co. were second. They

had a splendid pot of the yellow variety Mon Trésor, a variety of great beauty. Messrs. F. & H. van Waveren were again first with fifty double varieties, their third victory in the first show in which they have competed, a result highly creditable to these young growers. Amongst the best of their flowers were Tournesol Red and Yellow, and Tournesol Yellow; Murillo, blush; Couronne d'Or, yellow; La Candeur, white; Blanche Hative, pure white; and Turban Violet, violet. Mr. Polman Mooy of Haarlem was first with thirty-six doubles, and also with twenty; there was, however, nothing very noteworthy in the smaller classes for Tulips. Of the new varieties the most beautiful was one named Queen of the Netherlands, exhibited by Messrs. M. van Waveren and Sons. It is a very large flower, beautifully formed, soft blush, and as delicate and pleasing as a Tea Rose. Mr. P. W. Voet of Haarlem also showed a new double white named Snow White, which was honoured by the Jury. Tulips in glasses were also shown, and there were some excellent flowers amongst those of Messrs. L. van Waveren & Co., notably Joost van Vondel, Couronne d'Or, Proserpine, and Keyzers Kroon. Tulips are rarely grown in water in England.

NARCISSI.

These, as already indicated, were not shown to anything like the extent that they are at the spring shows in England. A length of 25 feet of tabling on the upper floor held the whole of them. Messrs. E. H. Krelage & Co. received the first prize for a collection of twenty-four pots. They had bico'or Empress, lorifolius Emperor, Henry Irving, Leedsiamabilis, Hudibras, Barri Cinderella, incomparabilis angustifolius, Sir Watkin, incomparabilis Figaro, Leeds Duchesse de Brabant, and other good forms. They were also first with fifty pots, these including, besides those previously mentioned, Capax plenus, pallidus præcox, Burbidgei Mary, major, and Countess of Annesley; princeps, bicolor Michael Foster, Achilles, Golden Spur, moschatus albieans, Johnstoni, conspicuum, &c., &c. Messrs. van Eeden & Co. also had a good collection.

GENERAL EXHIBITS.

Crocuses were not numerous. They were shown in pans in the English style, and being much the same as regards quality hardly call for comment. Anemones were not quite open, or they would have been a very attractive feature. Grown in close masses in 8-inch pots, they must be very beautiful when in full bloom. Amaryllises were very well shown by Messrs. van Eeden & Co., Schertzer & Son, and G. C. van Meeuwen. If hardly up to our best standard they approached it closely. Othello, Marie Stewart, Conqueror, Eneantress, Evening Star, Mahomet, Masterpiece, Minerva, and Paul Krüger were all very good.

Collections of miscellaneous flowers in the body of the building, arranged on the grass, were very attractive. One from Mr. van Meeuwen included Iris reticulata Krelagei, I. persica, I. persica purpurea, Chionodoxa sardensis, Cyclamen repandum, Lachenalia luteola maculata, Muscari comosa, M. moschata major, M. botryoides pallidus maculata, and other interesting flowers. In that of Messrs. van Eeden were a beautiful pan of Freesia Leichtlini, Scilla cernua, S. e. rosea, S. pyramidalis rubra, Corydalis bulbosa, Lilium Thunbergianum biligulatum, Iris Susiana, I. florentina alba, and others. From Mr. C. G. van Tubergen, jun., of Haarlem, came Tecophylæa cyanoerocus, Lachenalia aurea, Trillium sessile, T. erectum, T. grandiflorum, Fritillaria aurea, Iris Danfordiæ (Bornmülleri), Orchis undulatiflora, Aceras anthropophora, Orchis Robertiana, and many other plants. These groups were backed by Spiræas and Crown Imperials, and formed a very beautiful display. On an upper floor Mr. C. G. van Tubergen, jun., had a very interesting collection of dwarf Irises, including orehioides, tuberosus, Rosenbachiana, Cengialti, pumila var. lutea, stylosa var. persica, sindjarensis, and others.

In another issue something will be said about what, to most Englishmen, may be more interesting than the Exhibition—namely, the bulb farms. Several of them were visited, and as much information as possible derived about bulbs and bulb culture from those to whom bulbs are a life study. Shortly these farms will be in full beauty, and those who may be contemplating a holiday in search of health and recreation can hardly do better than run across for a few days in the first or second week of April. Haarlem is easily, quickly, and cheaply reached by the Great Eastern line from Liverpool Street, London, via Harwich and Rotterdam. The Dutch growers invariably give a warm and hearty welcome to visitors from England, and something will be seen that can be found nowhere else in the world.

ROYAL BOTANIC SOCIETY.

MARCH 26TH.

THE first spring Show of the present year in the Regent's Park Botanic Gardens was held on Wednesday, March 26th, and proved to be one of the best in the quality and variety of the exhibits the Society has yet held in this month. It was largely composed of non-competing groups and collections of flowers from nurserymen, the amateurs' exhibits and the competition in the classes being rather too restricted to be quite satisfactory. The corridor was filled, and a considerable space in the large conservatory was also occupied. The abundance of floral colour rendered the display very bright, but to produce a really tasteful effect more foliage was required, and it could not be compared in this respect with the summer Shows held on the undulated ground under the large tent. It is surprising that so little is done to diversify these spring Shows and introduce fresh features, though with so much material at command it ought to be easy to depart occasionally from the stereotyped plan.

Briefly noting the classes for competing exhibits we first come to the bulbs, and we find that with twelve Hyacinths Mr. J. Douglas, gardener to Mrs. Whitourn, Great Gearies, Ilford, was awarded the premier prize for excellent plants with very large spikes, the best varieties being The Sultan, Electra, La Grandesse, Mont Blanc, Vuurhaak, Czar Peter, King of the Blues, and Souvenir de J. H. Veen. Mr. H. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate, was second, and Mr. R. Scott, gardener to Miss Foster, The Holme, Regent's Park, third, with smaller plants. Messrs. Douglas & Eason were the prizewinners with Tulips, and Messrs. H. Williams, Douglas, and Scott were the exhibitors of Narcissi. Messrs. Paul & Son, J. Douglas, and R. Butler were the prizetakers for Amaryllises, all showing well. Cyclamens from Messrs. D. Phillips, the St. George's Nursery Company, and C. Nunn were well flowered as regards the two first-named.

Azaleas were bright and fairly good for the season. Messrs. Eason, Nunn, and Scott were the leading exhibitors in one class, and Messrs. R. Wells, Sydenham, and H. James in another, the plants of moderate size in each case. For six Deutzias Mr. Douglas was first, Mr. H. Eason being second with fine plants nearly equal to the first, and the Judges had some difficulty in determining their relative order. Messrs. Paul and Son, Cheshunt, were first in the two classes for hardy bulbs and hardy herbaceous plants, showing choice and interesting collections.

MISCELLANEOUS EXHIBITS.

Medals of various grades were awarded for the following exhibits:—Messrs. James Veitch & Sons, Chelsea, sent a group of Amaryllises, comprising some fine new varieties. Messrs. B. S. Williams & Son, Upper Holloway, had a similarly handsome group to that at the Drill Hall, Westminster, on the previous day, with some additions. Messrs. Laing & Sons, Forest Hill, showed a large miscellaneous group of plants, Orchids, Palms, Ferns, Azaleas, and Clivias predominating.

Messrs. Barr & Son, Covent Garden, had a large collection of Daffodils and hardy flowers. Messrs. Cannell & Sons, Swanley, showed Zonal Pelargoniums and double Cinerarias. The St. George's Nursery Company, Hanwell, had a large group of Cyclamens. Mr. J. James, Farnham Royal, showed a group of Cinerarias, and Mr. T. S. Ware, Tottenham, a grand collection of Daffodils.

Messrs. Paul & Son, Cheshunt, were the premier exhibitors of six Roses in pots, and they also had a large general non-competing collection of Roses. Messrs. H. Williams & Sons, Finchley, showed a large group of Hyacinths, Tulips, Spireas, and Narcissus.

Messrs. Wm. Paul & Son, Waltham Cross, had an extensive collection of Camellia blooms, representing all the leading varieties. Mr. Henry Bennett, Shepperton, had a box of the pedigree Tea Rose Princess Beatrice, extremely fragrant, fresh, and beautiful. Messrs. Cutbush & Son, Highgate, contributed a group of Epacris and miscellaneous greenhouse plants.

FRUIT FORCING.

VINES.—*Earliest House.*—The fermenting materials should be removed from the house before the berries commence colouring, retaining, however, about a couple of inches thickness as a mulch, and giving the inside border a thorough soaking with tepid liquid manure. After the Grapes commence colouring ventilate as freely as possible, and gradually reduce the atmospheric moisture. The temperature should be well maintained in the daytime, 70° to 75°, with 10° to 15° rise from sun heat, allowing the temperature to fall through the night to 65° or even 70° on cold nights.

Vines in Flower.—A steady circulation of warm rather dry air where Vines are in flower, with a temperature of 70° to 75° for Muscats and 5° less for Black Hamburgs, allowing an advance of 10° to 15° from sun heat, are essential. All shy-setting varieties should be fertilised artificially, dusting the bunches carefully with a camel's-hair brush, applying pollen from the free-setting varieties to the stigmas of the shy-setting sorts. We find it a good plan to brush over the bunches of the latter first, and then apply the pollen with another brush, this in both cases being used lightly.

Disbudding.—Do not attempt this until the bunches appear in the points of the shoots, and then it must not be done in a hurry, nor a large reduction made at a time, but proceed gradually and rationally, so as to give as little check as possible. Retain no more growth than will have full exposure to light, as crowding the foliage is one of the chief causes of disaster in Vine culture.

Stopping.—Wherever there is space allow the shoots with fruit to extend three or four leaves beyond the bunches before taking out their points. The laterals from the leaves below the bunches may be rubbed off, or they should be pinched at the first joint, but those above the fruit may be allowed to extend until the available space is fairly furnished, then pinch them and keep them within bounds afterwards by pinching to each joint of growth as made.

Thinning.—Remove all duplicate bunches before they flower, as it is

hardly likely one bunch well set well and the others indifferently. Free setting varieties may have the berries thinned as soon as they are out of flower, but Muscats and other shy setters should not be thinned until it is seen which berries have been properly fertilised. Instructions for thinning are extremely difficult to give, as the berries vary considerably in size in different varieties, and even different individuals of the same variety. Every berry should have room to swell without becoming wedged, and yet leave sufficient berries to ensure the bunch retaining its form when cut.

Watering, Feeding, Mulching.—From the time Vines are started there must not be any lack of moisture at the roots. It is not practicable to say how often the Vines should be watered through the borders being so variable in dimensions in depth and in their formation, as well as occupation with roots. A narrow border will need watering twice as often as one double the width, assuming the Vines to be equally extended and cropped, and a border of loose materials will require water much more frequently than one formed of firm retentive material, consequently the cultivator must be guided by the state of the Vines in relation to their rooting area. The proper plan is to examine the border, and when water is necessary give a thorough supply. Surface dressings of the approved artificials should be applied prior to watering, so that they can be washed into the soil in watering, or they may be applied in liquid form, a pound to 20 gallons of water being a suitable strength. The borders have been dressed at the usual season—i.e., whilst the Vines are at rest, a dressing after the Grapes are set, and again about the completion of the stoning process, will help considerably, the material as regards inside border being washed in immediately, or a soaking at those times with liquid manure, and when the fruit commences colouring will assure the berries swelling to a good size. In the case of Vines restricted to narrow borders higher feeding will be necessary, affording liquid manure whenever there is need of moisture. Supply a mulching a couple of inches thick of rather lumpy manure, the best being stable manure freed of the straw.

Late Vines.—Those that have commenced growth may be syringed two or three times a day as well as those that have not started, and to secure an even break close with a moist atmosphere at 75°, employing fire heat as may be necessary to secure a minimum of 55°. Vigorous young canes do not break evenly. To prevent a rush of sap to the upper part they should be brought into a horizontal position until all the eyes have started, when the canes may be brought up to the wires.

Young Vines.—Vines planted last season and cut back to the base of the rafter or trellis at the winter pruning must be encouraged by gentle fire heat, so as to allow time for their making and perfecting a good growth. The laterals should be pinched at the first joint up to a height of 6 feet, which will not prejudice but rather augment the supply of nutriment to the principal leaves, and by the additional food assimilated cause the formation of fruit buds. The principal leaves must not be crowded by laterals.

Vines for Early Fruiting in Pots.—Cut-backs of last year's raising should receive their final shift. The pots, 12 inches in diameter, should be clean and efficiently drained, potting firmly in turfy loam, with about a tenth of old mortar rubbish and a twentieth of crushed bones, adding about a quart of some artificial to every bushel of compost. Bottom heat is not necessary, but if they are plunged in it, it should not exceed 80° to 85°, and they must not remain in it so long that the roots enter the plunging material. Keep the house rather close, and if the weather be bright shade for a few days. It is essential that the canes be trained near the glass, to ensure the solidification of the growth. Pinch the laterals at the first joint, and treat subsequent growths similarly, stopping the lead at about 8 feet.

Planting Young Vines.—This will require to be effected when the growths are an inch or two advanced in growth. Where provision has been made for inside and outside border, plant the Vines in the former, which will be sufficient for the first year; indeed a 4 to 6 feet width of border is sufficient in the first instance. The Vines, if cut-backs of last year, may be shaken out and placed in position either before or after they have grown to the extent of a couple of inches, the roots being disentangled and spread out evenly in the border, covering them about 3 inches deep, and watering moderately to settle the soil about them. Vines of the present year's raising will not need to be planted out for some time yet. They are preferably raised in squares of turf, and may be planted when the roots are protruding through the sides, or if in pots they should be turned out before they become root-bound. They will require to have a temperature at planting out time suitable to Vines in growth—viz., 65° at night and 70° to 75° by day, with an advance of 10° to 15° with sun, but Vines of last year should be allowed to start unaided, syringing them two or three times a day according to the weather.

MELONS.—Early plants have made good growths, and are showing fruits upon the first laterals. To insure the fruit setting it is necessary to afford a bottom heat of 80° to 85°, and sufficient moisture only in the soil to prevent the foliage flagging. This will arrest growth, and in combination with a dry atmosphere—a circulation of warm air passing through the house—will favour the production of pollen. Fertilise the flowers every day, and stop the shoots one joint beyond the fruit. When the fruits commence swelling place warm soil against the sides of the ridges or hillocks. Supply water as required, avoiding a soddened condition of the soil, and to assist the swelling afford liquid manure, maintaining a good moisture by sprinkling every available surface morning and evening, and syringe the plants lightly at closing time in bright weather. If a succession of fruit be required in the same house some of

the plants should be deprived of the flowers if they appear on the first laterals, and stopping these at the third joint will cause the sub-laterals to appear and show fruit, which will be rather later and finer owing to the increased vigour of the plants.

Plants in pits and frames, with the shoots trained over the surface, will require to be treated in a similar manner to Cucumbers detailed below, lining the bed and adding to the soil as the plants advance in growth. Train and regulate the shoots, removing every alternate lateral, and apply water only to maintain a steady growth. The soil should be well firmed, so as to secure a sturdy short-jointed growth. As soon as the plants are ready they must be planted in beds properly prepared and seedlings potted. Seed may be sown to raise plants for succession, also for pits and frames as they become vacant through the removal of forced crops such as Radishes and Potatoes, about five weeks being required to secure strong plants.

CUCUMBERS.—*Pits and Frames Heated by Fermenting Materials.*—Beds that have been formed some weeks will need good linings. Remove as much of the outside of the beds as can be spared, and if the heat has not greatly declined it will suffice for the present if one half the bed be lined, deferring the other half until the heat is again declining. In any case let it be applied to a width of 2 feet, as thin linings are of little use and soon require renewal. When the heat is up in the linings see that there is no accumulation of rank steam in the frame, especially when the sun is powerful, preventing it by ventilation. A good night covering will be necessary to maintain a temperature of 65° to 70° at night. Admit a little air at 75°, and permit the temperature to increase to 85° or 90°, closing at 80° to 85°, not, however, causing the temperature afterwards to exceed 90°. Add a little more soil as the roots spread on the surface. Attend to training and pegging down the shoots, being careful not to overcrowd them. Stop the leading shoots a foot from the sides of the frame, and the laterals at one or two joints beyond the fruit. In watering avoid wetting the surface and foliage as much as possible. Sow seed to obtain plants for growing in pits and frames that have been occupied by early Potatoes.

PLANT HOUSES.

Lilium Harrisii.—Plants that have flowered should be cleared from aphides by fumigating with tobacco, and then place them in a cool house. Supply water carefully, and give weak stimulants occasionally, so that they will ripen their flower stems and mature their bulbs. If neglected in their present stage they will be useless, and might as well be thrown out as retained for flowering again. Later bulbs must be kept free from aphides, and should occupy a light airy position, so that their growth will be strong and sturdy. Later bulbs may be grown in cool houses, and may with advantage be given weak stimulants every time they need water.

Lilium candidum.—The earliest Lilies are pushing up their flower stems rapidly. Be careful not to hurry them in their present stage or half their flowers will fail to develop. Aphides are troublesome at this stage, and must be eradicated directly they are observed. Admit air freely whenever the weather is favourable, also supply weak stimulants. Plants in frames required to precede those outside should have the lights thrown off on fine days, or they will come forward too rapidly.

Late Primulas.—Sturdy examples in 4-inch pots should occupy a cool airy place with a moist base. Give clear soot water every time they need water. Where seed is saved select from the plants now pushing up their flowers the number required, and place the plants on a shelf with a sunny position, where they can enjoy a good circulation of air. To be successful in saving seed a fine camel's-hair brush should be used and the flowers examined daily. It does not take long with a fine brush to convey the pollen from the stamens to the pistil, which will insure seed pods. With many varieties this is the only means by which seed can be obtained. When seed pods are formed in sufficient quantity on each plant remove all the remaining flowers, so that the plants can devote their energies to the development of the seed. Do not neglect the plants in this stage, but give weak stimulants every time they need water. Keep the plants healthy until the seed is ripe, and not dried up as is too generally the case. For seed bearing it is a mistake to depend upon plants that have been flowering profusely for some weeks past.

Cinerarias.—Plants coming into flower will be plentiful at the present time, but the latest plants should be sorted without delay. These will be invaluable after Hyacinths are past their best. Place all the latest in cool frames where they are not too fully exposed to the sun and where abundance of air can be given during the day. It may still be necessary to protect them with mats during cold or frosty nights. The remaining batch may occupy a cool airy position in the greenhouse. These should have clear soot water every time supplies of water are needed.

Calceolarias.—These must not be checked or kept on a dry stage, or they are certain to be attacked by aphides, which quickly destroy them. The earliest plants must have a cool airy position in the greenhouse, and the stage upon which they are standing must be kept moist. Later plants will do in cold frames. They should be placed into their flowering pots from time to time as they become ready, for growth will now be vigorous and free providing they are kept clean. Do not allow the plants to become dry at their roots. On the other hand, if once the plants are well rooted liberal supplies are necessary. Clear soot water is very beneficial, and not only acts quickly but imparts to the foliage a fine dark healthy appearance.

Aspidistras.—Plants may be divided where it is necessary to increase

the stock. Those in 5 or 7-inch pots are the most useful. One large plant can be divided into a good number; one leaf and a lead is ample, and these should be placed singly in 3-inch pots and placed in a temperature of 55° to 60°. They will soon commence to root and become established, when they may be grown on in almost any position. They make greater progress in a little warmth than when grown perfectly cool, but they do not flourish satisfactorily in too much heat. Small pieces of this nature make excellent plants the second season if treated liberally from the time they are divided.

NOTES ON BEES.

ANTS IN HIVES.

"R. A. C." fails to keep ants from destroying his bees. The species known as the "large horse ant" infests his hives and kills the bees. The chalk line successfully used by the soldiers in India for keeping the ants from food is partly a failure with him.

There are numerous contrivances for preventing ants invading edible property which they are fond of. Moats are effectual, but some of them are expensive to furnish hives with. If hives stand upon a single post a zinc cup for the post with a hollow centre and the outer cup filled with some liquid will prevent any invasion. When the hive stands upon four legs any kind of cup or saucer may be employed. Deep-bottomed bottles are sometimes numerous enough about some establishments. By letting these into the ground neck downwards, and partly fill with water, then a little oil to prevent evaporation, the plan will be effectual. If rain can be kept out of them oil of itself will do. In that case the legs of the hive will not be injured by standing in it; but if there is water, a little block of wood or piece of tile or stone for the feet to rest on out of the water they will not decay. Carbolic acid is disliked by ants.

THE PUNIC BEES.

March has not been favourable for garden and field operations, nor for bees—at least, so far as it has gone, and we are now past the equinox. Our Punic stocks with two exceptions are the weakest we have. The black Punicians have been busy at work. Their industrious habits, together with their extreme hardiness, so far as my experience goes, augurs well for the future, and confirms "A Hallamshire Bee-keeper's" account of them. I trust that their important properties, so desirable and necessary in bees when profit is the aim, will be realised, and so confirm the rest that he has told us of the little strangers, which seem as docile as they are industrious.

DEVICE FOR HIVING.

An American invention, meant to prevent the loss of swarms, is made of queen-excluder zinc, in the form of a tunnel, having a wooden floor reaching from a hive likely to swarm to an empty one placed a few feet to the right or left of it. It has been improved upon in England by placing the empty hive in front. The idea is to induce the bees to swarm right into the empty hive in front. Will it succeed? Although much has been said in favour of the English improvement by doing away with a narrow portion in the centre of the tunnel, I am not hopeful that either device will succeed. They are, as yet, both untried.

When bees are in the act of swarming they are intent on flying at an increased velocity. The zinc, instead of leading them quietly to what might be their new home, will incite their frenzy to escape from the meshes of the zinc, which they are sure to do. If the queen is unable to get through, the bees outside will be apt to fly on to other hives, and if the weather is chilly many will be lost. Stranger bees sometimes kill queens of the hives they fly to, and by one mistake many hives might be destroyed. When bees are intent on swarming, instead of obstructing them give free passage, and let the queen go with them as an inducement to settle and cluster quickly. If a hive is supplied with one of the devices,

the queen kept prisoner, and the bees returning will simply cluster out, and in all probability the queen will be mutilated or killed, and a young queen will soon reign in her stead, much to the loss of the bee-keeper.

It is considered illegal and dishonest in Scotland to have decoy hives in the apiary; but when they are kept with an honest intention they need not be objected to. Hollow trees or boxes covered with bark, having some combs within, and under or opposite a door or hatch, are capital as decoys for swarms. We have had bees take to combs and store honey 3 feet from their hive, and knew of a bellglass belonging to "R. S., Dumfriesshire," filled under similar circumstances with pure comb and honey. I have also worked bees on the collateral principle, the hives standing some inches separate, but this is not commendable, and is not swarming.

I have used a tunnel covered with glass, fitted with two slides, when driving bees; when the queen appeared between the slides they were chased and the queen secured. The same device I have used for living bees, the tunnel being connected to the two hives; the one containing the bees had no outlet saving through the tunnel.

In the American device I have no faith whatever, and the English one is only a little different in form, which, owing to the bees' love of liberty, they will, I feel sure, reject. When bees take to a hive containing combs of their own accord the queen follows, but when force has to be used the queen enters reluctantly, and often deserts the furnished hive. It is good that this is so, or many hives would be destroyed, but the nature of the bee is against it. The knowledge of locality and sense of smell, so great in the queen, prevents her making any mistake to re-enter her own hive, although standing close to another. I do not believe queens get lost through entering adjoining hives, although reputed to do so. It is the bees that work the mischief; many cases of the kind I can trace to mere stupidity of the owner or his adviser, by manipulations quite uncalled for.

FEEDING.

Neglect of timely feeding now will prove disastrous to those in immediate want. From 4 to 6 lbs. of syrup given as quick as the bees will take it, will in no way injure the hive, nor the honey that may be taken further on in the year. Many stocks are far reduced in stores, but have in place many youthful bees, ready to take advantage of the early flowers and fruit blossoms that will be appearing in about two weeks hence, and swarming, weather permitting, will begin in May. In all my experience I do not remember a season when bees were so far advanced at this date as they are at the present time.—A LANARKSHIRE BEE-KEEPER.

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (E. H. and A. M.).—We have published the address you require so often that we fear the repetition is becoming tedious to some readers. It is Mr. Collins, 9, Martindale Road, Balham, S.W.

Calendar (S. O. G.).—We are not acquainted with any work of the precise nature indicated in your letter.

Spots on Peaches (F. W.).—The spot is caused by a fungus, but whether this is the result of the fruits not stoning as they should do cannot be satisfactorily determined. We rather suspect this may be the case, and if so the evil may arise from either defective fertilisation or a deficiency of calcareous matter in the soil. Try one of the fungicides, such as sulphur or sulphide of potassium to the affected fruits, also a copious application of lime water to the border.

Sowing Pandanus utilis (Seeley).—Do not attempt to break the fruit, i.e., seed, open, but place them in pots or pans of light soil—turfy loam with a third of leaf soil and a sixth of sand—placing the thick end downwards, point or small end upwards, and cover about an inch deep. Place the pots in a house with a temperature of 60° to 65° at night, and 70° to 75° by day, with 10° to 15° advance from sun heat; with uniform moisture plants will appear in due course, and when they are sufficiently advanced they may be placed singly in 3-inch pots. If two plants come from one seed, or "fruit," they are easily divided when potting.

Fragaria indica (Idem).—It is a pretty greenhouse plant, with red, insipid fruit, yet decidedly ornamental. It is of trailing habit, like the Strawberry. Seed may be sown in pots or pans, just covering the seeds, and placing in a house where there is a gentle warmth. Let them grow near the glass, and when large enough place singly in 3-inch pots, shading from bright sun until established. Eventually remove them to a greenhouse, and shift into larger pots as required. Six-inch pots are sufficiently large for fruiting. Accord the same soil and treatment as to Strawberries in pots.

Strawberries not Swelling (Anxious).—The misfortune is due to the too hasty development of the flowers. They are perfect as regards the calyx and corolla; the stamens too may acquire their yellow colour, but are useless if the pistils are a mere tuft of abortions, and shrivel into black masses. This can only be prevented by giving the plants more time. They require to be brought on very gradually, growing them slowly until the fruit is set in order that the parts of fructification may have time to form, as they naturally do, in gradual succession. We have not found either the Captain or Noble suitable for early forcing, though good for succession. As an early forcer we have found La Grosse Sucrée one of the best.

Value of Asparagus and Seakale (E. E. W.).—Your district produces some of the finest Asparagus in the country, and you ought to be able to obtain some valuable information from local growers. Much in every case depends upon the suitability of the soil and the method of culture adopted. If your land resembles that of the Vale of Evesham generally it will stand abundance of manure, and the Asparagus will succeed best planted on the level. The rows ought not to be less than 30 inches apart, a similar distance dividing the plants in the rows. In this case you would require about 7000 roots for an acre of ground. Not till these have been planted five or six years will they be very profitable, but if well attended to they will continue improving in value for many years. When in its prime an acre of Asparagus ought to be worth £200. You omitted to state whether the Seakale is to be lifted for forcing, or grown or blanched on the same ground for several years in succession. Supposing the former plan is intended you would require about 23,300 roots or cuttings, putting these out 18 inches by 15 inches apart, and if very good their market value at the end of the season would be somewhere about 10s. per 100.

Mildew on Roses in Conservatory (St. Julia Arabi).—Mildew is apt to prove destructive in injudiciously ventilated structures. It may often be checked or even prevented by attention to ventilation. Sulphur has proved the most reliable means of destroying the fungus. Flowers of sulphur dusted over the affected parts will destroy it, but as this may be inconvenient, boil 1 lb. flowers of sulphur and 1 lb. of quicklime in 3 quarts of water in an earthen vessel for fifteen minutes, keeping constantly stirred while it is boiling; allow to settle, and pour off the clear liquid for use, keeping it in a well stoppered or corked bottle. A quarter of a pint of the lime and sulphur preparation should be added to 3 gallons of rain water, and the Roses infested with mildew syringed with it thoroughly so as to wet every part. Allow the foliage to become dry, and in the course of a day or two repeat the application. Two or three syringings will mostly eradicate the fungus. As a preventive the Roses may be occasionally syringed with a weak solution of softsoap, a couple of ounces to a three or four gallon watering pot of water, using it in a tepid state or 90°, thoroughly dissolved and mixed. Keep the roots moist, and take care that cold currents of air do not drive against the plants.

Barbe de Capucin—Haricot Beans (Inquirer).—The Barbe de Capucin of the French is the growth of the common Chicory, forced in the dark, and used as salad. Some persons like it cooked, but for this purpose the large Brussels Chicory is preferable, the crown being made to push through 7 or 8 inches of light soil in the open, or for early use forced in the dark. This is known as Witloof. Sow seeds of either or both in drills 18 inches apart in deep rich soil in April or early May, thin out the plants as if they were Parsnips, and you will have good roots for forcing in the autumn. You can procure either tall or dwarf Haricot Beans from seedsmen. They are varieties of Kidney Beans, the tall sort sown and supported like Scarlet Runners, the dwarf like the so-called French Beans. The seeds are cooked when they get firm, also when gathered before they get quite hard, all through the winter. There appears to have been a little delay in the

delivery of your letter, but these replies are quite soon enough for your purpose.

Angelica Culture (F.A.).—It grows well in any good soil, but succeeds best in cool and moist situations, so that instead of a south it should be given a north border. It is raised from seed which may be sown now, or preferably in August, or as soon as the seed is ripe. The seed bed should be frequently watered if the weather be dry, also the young plants. If sown in spring they should be thinned to 2 feet apart every way, allowing them to remain where sown, or if sown in August or September the plants should be planted in March 2 feet apart every way, keeping them free of weeds and in dry weather affording plenty of water. The stalks will be fit for use in May or June of the following year, when the stems should be cut down so as to keep the plants from flowering and seeding, then they will live for three years, otherwise the plant is a biennial. The preserved Angelica you mention is in all probability grown in England, it being very extensively grown about London many years ago.

Arum Lilies and Freesias for Market (C. M. E.).—Arum Lilies meet with a ready sale and fetch good prices, or, say, not less than 6s. a dozen wholesale at Christmas and Easter, and they also sell fairly well at other times. You cannot do better than grow them extensively, but you will have to completely change the flowering season, as it is very certain plants flowering in June would be of no value for midwinter work. What you have to do is to retard growth as much as possible, and this can best be done by lifting the roots at once and exposing them to what cold winds you may experience in your somewhat favoured Isle of Guernsey. They will stand much rough usage, but should be replanted in a cool position before the growths are far advanced. After the houses are cleared of Tomatoes the Arums might be lifted and replanted in the borders not later than the first week in October. This class of plants will be treated upon by our correspondent "M. H.," and probably you may be able to glean a few serviceable hints from his paper on the subject. Freesias are fast becoming popular, and there is a fairly good demand for the white variety (*F. refracta alba*) especially. Unlike several other bulbous rooted plants that could be named, the same stock will improve in value after the first year, and their cultural requirements being of the simplest description you could grow them extensively without adding to the working expenses of your establishment. Christmas Roses pay well, and so also do late Chrysanthemums, these being grown in the open ground and transplanted to the borders in light structures. Why not grow *Narcissi* extensively on the same lines as adopted on the Scilly Isles?

Increasing Lobelias (J. S.).—The ordinary bedding Lobelias are propagated by division and cuttings in preference to seedlings, the latter rarely being sufficiently neat-growing. Bluebeard, *pumila magnifica*, and Brighton are all excellent blue sorts, and supposing a number of plants of either of these have been wintered in boxes in a rather low temperature, on being introduced into an early vinery or in a moist heat every shoot will quickly emit roots. These may be pulled off and dibbled in rather thickly in boxes and eventually bedded-out in cold frames, or, if a little bottom heat is available, these divisions may be placed on beds of good soil and about 4 inches apart each way, where they will soon grow to a good size, the frame or lights being then available for other purposes, some other protection being provided for the Lobelias. Thousands of good plants may thus be raised without much trouble. Seedling Lobelias should be pricked out before becoming crowded and weakened. The herbaceous sorts may be divided when the suckers are well above the soil.

The Lackey Moth (Subscriber).—The following methods of prevention and remedies are recommended by Miss Ormerod:—"Some good may be done by looking for the rings of eggs on the shoots, cutting these off and destroying them; also by destroying any yellow silken cocoons that may be found about the trees; but these methods are tedious, and, though they are of use where just a few trees can be carefully tended, are of little service in orchard treatment. A far better way is to watch for the webs, and, as soon as they are seen, to carry out the old French method and cut the shoots through with a pair of nippers and destroy them. It is well for one person to cut and another to hold a pail below for the web and all the caterpillars (which on the first alarm would throw themselves down by their threads) to fall into. The pail should have a few inches depth of water in it, or mud thick enough to prevent the caterpillars from escaping. A less troublesome but less complete method is to shake the boughs, or strike them smartly, so as to make the caterpillars drop, and sweep those that dangle by their threads in the air down with the hand. These may be trampled on, or gas-lime, quick-lime, or anything that will kill them may be thrown on them, but it should be done at once. As the moths harbour under leaves and long grass, a properly kept state of undergrowth in orchards, free from overwhelming weeds and rank herbage, is of service in preventing attack. Much more attention to this matter is needed relatively to keeping down Apple pests than is commonly supposed. The dark, damp, confined air of the neglected overcrowded orchard fosters all kinds of insect pests, and as no grass cut in such circumstances would dry it is often left for rough feeding, or an occasional "skirming" of what is too long to remain uncut, and thus "pests" have possession; whilst where the trees stand apart, as they should, there is sunshine and fresh air to cause ripened growth, and lighten up the dark nooks that insects hide in. The grass can be properly pastured and attended to, and also the small birds have fuller access to do their work as insect-clearers."

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*J. M.*).—The stewing Pear is Catillac. (*Henry Jones*).—The Apple sent is assuredly Ashmead's Kernel; the other must be wrong. (*F. K.*).—Not in condition, soft, bruised, mealy, and cannot be named.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*C. N.*).—The plant is *Selaginella lepidophylla*, and will revive if placed in water, or it can be potted in peat, and will probably recover and grow if placed in a stove or any warm house. (*J. A. W.*).—We cannot undertake to name Roses; see our regulation above. (*S. T.*).—1, *Iris reticulata*; 2, *Anemone fulgens*; 3, *Anemone apennina*; 4, *Leucocym vernum*. (*W. R. B.*).—1, *Odontoglossum Edwardi*; 2, *O. Cervantesi decorum*; 3, *O. blandum*. (*X.*).—1, *Adiantum macrophyllum*. 2, *Lomaria blechnoides*; 3, *Lomaria gibba*. (*R. H. F.*).—1, *N. Telemonius plenus*; 2, *albicans*; 3, Too withered for identification.

COVENT GARDEN MARKET.—MARCH 26TH.

MARKET still very quiet with early forced goods in fair supply, and prices barely maintained.

ENSILAGE.

In our farm work note last week one or two hints were given about the sowing of special fodder crops now for conversion into silage in July. This was mentioned as an ordinary detail of farm work, but a little thought subsequently brought conviction that it is by no means a part of ordinary farm practice, that silage stacks are still an uncommon thing at farm homesteads, and that the matter was of such importance as to be worthy of more prominent notice.

For ensilage to supplant either haymaking or root crops, or both, its real value must be ascertained by actual experience; and this little golden bit of practical knowledge, this new influence upon the prosperity of agriculture, should no longer be left in the region of doubtful things, but be tried out by every farmer, and more especially the heavy land men. To farm strong land at all now requires extraordinary ability if it is to be done successfully, and if only a tithe of the pains bestowed upon root culture in such land were given to ensilage, the certain resultant benefit would ensure its speedy adoption; for root culture in a clay soil is always a speculative matter, and root crops are so expensive that they would certainly be avoided altogether if only farmers knew how to do it.

Let us briefly glance at the advantages of ensilage. Given the materials it enables us to ensure an ample provision of winter food for cattle, horses—aye, and sheep too, for even lambs will eat and thrive upon it. Silage is at least as wholesome, nutritious, and palatable as the best meadow hay, and it is cheaper than hay or any other cattle food, for not only is the bulk of it per acre much greater than any other stored forage, but the process of ensilage is so simple, and withal so sure, that the entire outlay involved consists in the cost of mowing, carting, stacking, and pressing the forage. Costly means of compression may be avoided. The first silage we made was pressed with boxes filled with iron slag—gravel or sand would have answered equally well, and on page 166 a correspondent tells how he had made good silage of aftermath stacked and pressed by bricks. We have only to try and get as full and bulky a crop as we can, and we can mow, cut and stack it whether wet or dry, only we must be careful to put on the pressure at once. That is all; can anything be more simple? Of crops suitable for ensilage besides meadow grass there are Lucerne, Tares, Oats, Rye, Italian Rye Grass, mixed layers of grasses and Clovers and Trifolium. Two bushels of Tares and 2 bushels of Oats per acre make an excellent mixture for silage, or we might use only a bushel of Tares and add a bushel of Italian Rye Grass. As we pointed out last week, by sowing at once the crop would be ready for stacking in July, so that it might be cleared, the silage made, and the land prepared for Wheat before the corn harvest begins. The cost, anxiety and uncertainty of root culture would thus be avoided and an ample provision be made for winter of sound nutritious food.

The cheapness of hay during the past winter ought not to induce carelessness about ensilage. The abundance of good hay made last year cannot make us forget the lamentable failure of the supply after the wet summer of 1888. We are now using for litter a stack of 1888 hay, which we had to take in valuation last Michaelmas. The owner of this stack of spoilt hay could neither use nor sell it, and so got a trifle in valuation when he left his occupation. Had it been made into silage it would have been just as valuable for home consumption as the best hay. A wet season or two would tend more to popularise ensilage than anything else. Yet we cannot but regret the general slowness to

adopt a process that is so eminently calculated to promote the general good.

We have given root culture a fair trial at a clay farm for four consecutive years. A considerable quantity of white Turnips, Swedes, and Mangolds have been grown every year, but we have not had a full crop of all of them in any one year. Last year it was the Mangolds which failed us, and we did not get more than half a crop. The bailiff was loud in his complaints about inferior seed, but we could not agree with him, for our seed order was sent to an excellent firm who supplied all our farms, and as usual the result was very much in accordance with the nature and condition of the soil in which the seed was sown, with the exception that on the light land of the home farm the Mangold crop was for once superior to that of the mixed soil farm, owing to the fact of the season being so favourable for light land. The soil of the heavy land farm that is so inimical to the growth of roots yields heavy crops of most forage plants—*ergo*, a greater area of that farm has been devoted to forage crops of all kinds year by year, and there has been a proportionate curtailment of root crops. By ensilage we are always able to insure an ample supply of winter food; but we do not go to a ridiculous extreme with it, but make some hay, graze a considerable number of home-bred cattle and sheep, and harvest as much Clover and Sainfoin seed as we can.

WORK ON THE HOME FARM.

In top-dressing winter corn some judgment is required, because the condition of the plant now should be our guide in what is done. Our knowledge of the condition of the soil too must also have its due influence upon our decision, and there should be no line and rule work at all in the use of manure. When a recipe of the best chemical manures is given for a top-dressing it becomes a matter for each individual to decide upon. Do all or any of my Wheat fields require such help now? If the land has the benefit of thorough cultivation, if no crop has been sown for some time with a manure dressing, and if the plant of the present crop by its robust vigorous appearance shows that the soil is rich in fertility, then let us by all means let well alone, and reserve the manure for some other purpose. But if the fertility of the soil is low or even doubtful, and the plant though healthy enough is somewhat weak, then apply a top-dressing at once. Or if a yellow failing plant conveys unmistakeably to the eye intelligence of the presence of wireworm, then top-dress at once and follow with a cross-hill roller, which if it does not crush the wireworm serves, at any rate, to close the soil and so check its depredations that the plant under the fillip of the manure grows out of harm's way before the wireworm can get at it again.

Lent corn has gone in well, Barley especially having quite a model seed bed for once both in the autumn ploughed land and in recent ploughings after the sheep folds. The temptation to sow this favourite crop is more than usually great, but pray remember, Mr. Heavy Land Farmer, that though you may have got a heavy seed bed, yet how often has your Barley failed through unkind weather at critical stages of its development later on. Why, therefore, stick to a crop which has so often failed you? Rather, much rather, sow a good sample of Black Tartar Oat, and do try not only to do yourself some good, but also to raise the shamefully low average of this much abused and neglected crop. The ordinary average of the Oat crop in Great Britain is 30 bushels per acre, the possible average is more than twice that quantity. Need we point the moral?

METEOROLOGICAL OBSERVATIONS.

REMARKS.

16th.—Sprinkles of rain at 7 and 9.15 A.M., and in afternoon, otherwise generally bright.
 17th.—Brilliant morning, fine pleasant afternoon.
 18th.—Cloudy early, bright day; shower in evening.
 19th.—Wet till 10 A.M., then cloudy, and occasional drizzle in afternoon.
 20th.—Very wet all morning, then dull, damp and showery.
 21st.—Bright early, then cloudy and spots of rain at 11 A.M.; fine afternoon with occasional sunshine.
 22nd.—Wet early, cloudy from 9 to 11 A.M., then fine and bright; solar halo at 3 P.M. and spots of rain in late evening.
 A damp week, with low barometer and temperature near the average.—G. J. SYMONS.

IT does not follow, as most persons know who have had much experience in fruit culture, that a great display of blossom always results in abundant crops of fruit. On the contrary, it will be within the knowledge of not a few readers of these lines that when trees have been densely packed with flowers in spring they have often been almost or quite destitute of fruit in summer, and this when the weather has not been regarded as unfavourable for fructification. When the blossoms are so crowded on spurs and sprays that they have not room for expansion we can scarcely expect that they should be so strong and perfect individually as if they were more thinly disposed, and we think it has been found that the removal of blossom buds before expansion—thinning out much more than half of them—has been advantageous, those remaining having developed better, and set fruit accordingly. The practice, for obvious reasons, could not be pursued through extensive plantations of fruit and with large orchard trees; but the experiment is well worth trying on small trees, from which a moderate crop of fine fruit is more desirable than a heavy and exhausting crop of small trashy examples, and certainly than no fruit, as when all the blossoms fall from the trees that were clothed with them so completely. When this happens under favourable weather conditions at least one cause of the supposed mysterious occurrence is probably the inherent weakness of the blossoms as the result of overcrowding.

Fruit crops fail from other causes, and unfortunately it is not in the power of man to prevent the calamity. Sharp frosts at a critical time have often destroyed the essential organs of the flowers, though the petals have expanded as if nothing was amiss. The prospect of fruit was of the brightest, but the beautiful spectacle of the chastely robed trees was delusive. It is possible that this may have been the case with Apricots if not Peaches in some districts last month, when they were overtaken by the sharpest frost of the winter. Ordinary nets are useless against such a visitation, while keeping trees covered with heavier material day and night during all sorts of weather is no security against failure, and in many cases at least as much harm as good has been done by permanent blinds. When the blinds are moveable, and only used when needed, also stout enough to shield from even a severe frost, they are of great service, and have often prevented the loss of what they have saved—valuable crops of fruit. Fruit fails to set through other elemental conditions. Continuous showers and moisture-laden atmosphere for a week or more have prevented the dispersion of pollen, and destroyed all hope of the setting of fruit. Weather the direct opposite in character has had similar results; unclouded sun, parching winds, and dewless nights causing the flowers to wither prematurely, and leaving no fruit behind them. Such visitations have often been stern realities, and may be again, though we hope not this year; but because of the possibility no one can be assured that a good show of blossom will be followed by a rich harvest of fruit, yet we are all pleased to see the blossom.

Its safety or otherwise often largely depends on the period of its expansion, and to some extent possibly on its structure, but more than all on the position of the trees. It does not follow that early flowering varieties succumb because of their precocity, and late blossoms escape because of their tardiness in expansion,

for if the weather is favourable for setting when the early openers are in full floral beauty, and unfavourable when the late flowering sorts are similarly gay, the former consequently bear good crops of fruit, the latter light crops or nothing. Hence it sometimes happens that Pears are abundant and Apples sparse in the same garden. It is fair to assume, however, that the later the flowering the better the chance of favourable weather prevailing at the time, and that may be one reason why Apples over a series of years are more certain in crops than are Pears, while late flowering Apples are perhaps, as a rule, the more reliable; but there are exceptions.

Some most interesting and painstaking experiments, conducted by Mr. William Paul, were recorded in the *Journal of Horticulture* of March 6th of the present year. He there states the period of flowering of a number of varieties of Apples, and indicates the size, shape, and texture of the petals of each. Perhaps most persons would consider the good bearing varieties in that list, which flower after the middle of May, somewhat more reliable than those which expand early in the month. Still, amongst these we find Duchess of Oldenburg and Keswick Codlin, which are as trustworthy as most; also Tower of Glamis. In the second week we find among others Lord Suffield, Devonshire Quarrenden, and Manks Codlin, which usually bear well; but with one exception those named have cupped flowers, the petals curving over the organs of fructification and affording them slight protection, though it may not be without favourable influence. Still, perhaps the later flowering sorts are the more certain in bearing, though it is noticeable that the half dozen that opened after the 21st of the month (May) have expanded flowers. Possibly gardeners and amateurs who are interested in fruit culture may take notes on the flowering and fruiting of trees during the season on the lines adopted by Mr. Paul.

The position which trees occupy is an important factor in the production of fruit. Given equally fertile soil, and the same varieties, grown in a damp valley where fogs appear early and continue long; also on a breezy hillside—the blossoms will be destroyed by frost twice as frequently in the former as the latter position. Yet where there has been plenty of choice, fruit trees innumerable have been planted where they were the least likely to be productive. It is a pity that should be so, but it is a fact, and the penalty for such mistakes is the annoyance born of disappointment.

The promise of fruit this year, as indicated by the blossom, is necessarily variable, and we shall be glad to be favoured with the observations of our readers in different localities on the subject. In the Royal Horticultural Society's Gardens at Chiswick the prospect is not very cheering. There is plenty of Peach blossom, and so far it is safe; Pear blossom will be scant. A few of the trees are well studded with the buds just bursting, but many more are barren, and the majority have a very light sprinkling. There will not be half a crop of fruit even if the flowers set well. The Apple trees will not be "pictures of beauty" in May. Several contain sufficient buds for a crop, but the majority do not, and the fruit room will not be overcrowded in the autumn. The small bush Apple trees have been heavily laden during recent years, therefore require a season for recuperation, and some of them intend having one. Plum blossom is scant, and it is the same with many of the older trees in the adjoining market gardens, but young trees are well covered with flowers. Cherries are not usually productive at Chiswick, but there appears to be a fair promise of bush fruit.

On this subject we have received two communications. Mr. Iggulden writes from Somersetshire:—"The late severe frosts have left their mark upon the Apricots, and I am afraid the Peaches are not in such a happy state as they appear to be. There is abundance of blossom on the former where protected by coping and blinds, but in too many instances this is delusive, as the delicate organs of fructification so neatly enclosed in the buds were

killed. Cherries as usual are well furnished with buds, which were not forward enough to be injured. Plums are very thinly set with buds, but much of this scarcity is due to a plague of bullfinches, hundreds of which were killed in this district. Pears are exceptionally floriferous; in fact I wish there was much less bloom on the trees, and this stronger. No injury has accrued to it, and the Jargonelle will soon unfold its very fine showy trusses of flowers. Apples again are most abundantly clothed with fruit buds, never more so probably, and all being well there ought to be no scarcity of fruit next autumn and winter. Bullfinches have simply ruined the majority of unprotected Gooseberries, and Red Currants have not wholly escaped, while every Medlar bud appears to have been taken by these pests."

From Hertfordshire comes this report:—"Gardening prospects, like farming prospects, to which they are closely related, are very uncertain of realisation, but still it is pleasant to have them good. Taking the Apple first, as of primary importance, I may safely say that we shall have plenty of blossom, even more than last year, though we had a great deal then. I do not think the Apple buds too forward, but they are distinctly swelling, amongst them such excellent sorts as Duchess of Oldenburg, Warner's King, Cox's Orange Pippin, Lord Derby, Northern Greening, Hawthornden, Ecklinville Seedling, Devonshire Quarrenden, Keswick Codlin, Lord Suffield, and Mère de Ménage, which is usually shy here. Plums rank next in importance, and I think, as far as profit is concerned, they are more remunerative than the Apple. We have a capital collection, and generally succeed in securing heavy crops. The Victorias are very full again; Black Diamond promises as well as ever, but this Plum is rather erratic in its temperament. I think it requires a lighter soil than the generality of Plums. Here (Herts) it is one of the most profitable grown; the individual fruits are as large as duck's eggs, and the crops enormous, but I am familiar with a large quantity of really good trees about four miles from me that never yield a crop, while the Victoria flourishes well. Pond's Seedling is also very good, but the fruit will not stand the wet. Oullins Golden, Green, and Rivers' Early Transparent Gages all promise splendidly. Early Prolific is very full. Magnum Bonum, Orleans, Coe's Golden Drop, and Cox's Emperor are all looking well. Pears are rather uncertain here, but this year we have a splendid show of bloom. The bullfinches have been very troublesome this season, particularly in one garden. A great living naturalist has said recently that these birds are Nature's own pruners. Such pretty little pieces of sentiment are picked up with your feet placed cosily in front of the fire, and a book about the pets in your hand. What a boon to the gardener! He has only to leave the trees alone, and allow the bullfinches to do the pruning. Whether the birds are Nature's pruners or not, I prefer to do my own pruning or thinning the buds, as the case may be. I have lost the whole of the buds of Louise Bonne de Jersey from some young trees. Williams' Bon Chrétien, Duchesse d'Angoulême, Pitmaston Duchess, Beurré d'Amanlis, and Easter Beurré are looking exceptionally well. Peach and Nectarine trees are covered with expanding blossom. I have only just had the trees nailed to the wall. Hale's Early Peach was in full bloom, but I do not mind knocking some buds off when nailing, provided I can retard the opening buds, for I consider every day later is a day safer. Gooseberry, Raspberry, and Currant bushes I cannot say much about, but the leaves are breaking freely on the Gooseberry bushes. I have only one Apricot tree, and that does not pay for the space occupied. As I said before, these prospects are not much to go by, for we have much to encounter and contend with before we see any signs of the fruit crop of 1890."

THE PRUNING KNIFE.

THERE is no necessity for giving a definition or the history of this useful instrument, but as there are two sorts in the market, the good and the bad, the young gardener should take pains to

secure the former, if possible, and keep it in good working order. There is more in this than at first appears, for a young gardener's success may depend very largely upon the possession of a good knife, the condition he keeps it in, and his skill in using it. We might give numerous illustrations, but will confine ourselves to one or two which will suffice to show the advantage of possessing a sharp knife and the evils which may arise from the use of a dull cutting one. Let us suppose our young gardener sent, at this season of the year, to re-stake some young Melon plants. He begins sawing away at the old ties with his bad cutting knife, and in doing so the matting has cut into the tender stem perhaps sufficient to completely ruin a plant that has taken two months of anxious care and stratagem to raise it, or it may be the bruise is slight and goes unnoticed until the fruit arrives at the last swelling stage, then all at once the plant gives out. Such misfortunes may occur from canker alone, but the bruise given to the tender stem when trying to cut the matting with the blunt knife may have been at least the exciting, if not the sole cause of the evil. Then who shall estimate the number of cuttings ruined every year through being made with a blunt knife, and the consequent loss and disappointment? It is no small matter for a gardener to possess a bad cutting knife, whether the fault lies in the knife or its possessor, and the young aspirant should spare no pains to remedy the evil. Great and important matters are always sufficiently exciting in themselves to secure our continuous attention, but the apparently small matters are apt to become the "weak links in the chain," and since our true worth is proportionate to the strength of our weakness, these are the points which demand our greatest attention if we wish to excel in gardening or anything else.

But the man who possesses a good knife and has mastered its uses in every detail is of no mean order, whatever may be his "social position," for his knowledge of plants individually and collectively is great. This man's theoretical studies and practical applications have been long and arduous, and we can only attain to his position by a like process.

But even such men as these are not always able to act up to the standard of their knowledge, since the plants they would with advantage operate upon are not their own, and since the owners of these plants from want of practical knowledge are often unable to comprehend the gardener's arguments for pruning certain plants, he has to be content to keep his knife in his pocket and from year to year have unsatisfactory plants under his care. Circumstances such as these are calculated to diminish a gardener's zeal and to lead to general carelessness, since it more or less ties his hands and stifles his ambition. There are times, however, when the gardener, by examples and explanations, will gain confidence, and in most cases it will only require steady application and time to gain permission to use his knife to his heart's content.

Now his time has come, and his promises to those lanky, bare-stemmed Camellias, Orange trees, and other plants—to those sickly wiry-looking Azaleas that have been carrying heavy crops of flowers the past ten years, will soon take practical shape, and as soon as he starts his vinery, or has plenty of heat and moisture at command, these plants will bear a close resemblance to an old Apple tree prepared for grafting. Some would be dubious about these smooth-stemmed Camellias ever growing again, but an inspection in three months' time may tend to caution them against limiting the powers of Nature. With a due regard to atmospheric and root conditions, it is wonderful what a judicious use of the knife will do for them and other hardwooded plants in two years. From objects to be shunned they will have become thick well-shaped bushes, and a credit to all concerned. The intelligent use of the knife has saved the life of many a plant, and hundreds have died through the want of it.

The gardener who has mastered the use of the knife will also know not only when to use it but when to avoid using it, and how to prevent having to use it. There are few good things in this world but what may be abused, and the pruning knife forms no exception, and so it happens that many people continue pruning their trees, especially fruit trees, without having any clear idea why they do it or how it should be done. They get very few flowers or very little fruit, as the case may be; but then that is not the fault of the pruning, for how are trees to be kept within bounds except by cutting off all the summer shoots? besides, their fathers pruned in the same way. Happily, instances of this sort are becoming less every year, and the majority are realising the fact that the roots must either be restricted or frequently pruned in all cases of formal training, especially if that training does not allow of the full development of the tree. To allow a thicket of shoots to grow on a fruit tree simply to be cut off at the end of the summer is not only a waste of time and material, but a strong invitation to sterility, disease, and death.

The above remarks, of course, apply principally to fruit trees, but there are certain Roses and other flowering plants that must

receive a severe pruning yearly to secure a strong growth and abundance of flowers. The chief business of the pruner will be to ascertain when the pruning must be done, whether before or after the flowering period, as ignorance on this point may lead to the loss of a whole season's crop and other serious consequences. I was called in last summer by an amateur to give my advice respecting a *Maréchal Niel* Rose that had become very unsatisfactory. He had planted it in a well prepared border in his greenhouse five years ago, and the first year it completely filled his house with long healthy shoots, and the following spring it rewarded him with a splendid crop of good blooms. This stroke of success naturally heightened his ambition, and as he had made a good round sum of his blooms, he decided it would pay him to give up his greenhouse entirely to them. His house had already become crowded with shoots, and he saw that something must be done to give them more room, and not knowing how to proceed he sought the advice of a florist, who told him that "he must never, on any account, prune a *Maréchal Niel* Rose, or it would never flower." The amateur, believing this statement, and determined not to be defeated, removed the gable end of his house and added a new length equal to the first, with the intention of covering its roof with the Rose shoots. In a paper like this Journal it is scarcely necessary to say that the man was sadly disappointed, and too late he discovered that he had been "sold." For the last two years the plant had only shown a few yellow sickly buds that fell off without opening. I told him how we managed ours, and advised him to do likewise—namely, to select the best main branch, and carry it horizontally along the bottom of his house, and from this branch, at about 15 inches apart, to train strong shoots to the top of the house, and to be very careful to keep them tied straight up so as to prevent any of the eyes breaking. In the spring, before starting the plants, these shoots are taken from the vertical position and retied in an oblique manner, so as to induce all the eyes to break the entire length of the shoot. When the shoots have done flowering they are boldly cut back to one or two eyes at the main horizontal branch. The above is a case in point of loss and disappointment through not knowing how and when to use the knife.

Before commencing to prune any plant let us have a clear idea of what is the object in view. If we are pruning for shape, let us endeavour to picture how the plant will appear when its growth is finished, and then cut accordingly. If flowers are our aim, then we should know whether the plant flowers best on strong, moderate, or weak shoots; also we must know whether it flowers on the current or previous year's growth; and finally, if we are pruning to obtain fruit, we must take not only the branch but the root into consideration, and even individual varieties of the same fruit may require different pruning. We cannot expect to exhaust this important subject in a short paper like this, but enough has been written to show the necessity and advantage of a good general knowledge of plants and trees in order to use the knife with credit and profit. To secure this desirable end, young gardeners would be well repaid by mastering at least the elements of vegetable physiology and collateral subjects, as it would save them from many doubts and mistakes, and supply them with the "why" and "wherefore" certain work is done.—J. H. W.

CULTURE OF SEAKALE—HOW TO PROCURE A SUPPLY FROM SIX TO SEVEN MONTHS.

WE often have useful articles written by practical gardeners in the Journal about growing and forcing this winter vegetable, but there usually seems to be something wanting to complete the instructions for growing it to the best advantage for ensuring the longest succession.

In referring only to the beginning of this year I find three notices of Seakale forcing—the first on January 2nd, page 3, by Mr. G. Hilton, recommending forcing it in champagne boxes on the top of boilers. I think any place is preferable to that where there is heat to about 56° or 60°, as under stages or in Mushroom houses. Many other places could be found equally as well suited, including unused cellars, and much more useful than the above is a large bacon box. Before using the bacon boxes I fit four pieces of wood on the sides about 4 inches from the top (the inside) of the box, and after the crowns are planted firm and watered and left a day or two to dry, the space of 4 inches or so at the top of the box is filled with dry grass, hay, or dry litter, which keeps it airtight and prevents the Seakale turning green or a bad colour. The boxes are sound and strong, and can be had for about 1s. deep enough for about 18 inches of heating materials such as hot manure, short horse droppings, leaves, or cocoanut fibre. It helps to keep the Seakale moist, for if placed on a damp base it will only need one good watering when first planted. If

the heat is from 55° to 65°, the Seakale will be fit for cutting for table in six weeks, and later on in four weeks. In this Journal on January 30th, page 89, was an article by Mr. A. Thoburn, which was very good as far as it went, and applicable when the weather is favourable outside; but how would it be when we have from 8° to 20° of frost? A further supply could be had from February to the end of March, or the second week in April if a backward spring. It may also be forced in the old-fashioned way with proper Seakale pots and leaves or manure, but care should be taken not to have the manure hot enough to scald the crowns, as described by Mr. A. Thoburn.

From April to the end of May cover the crowns with shingly pebbles or fine gravel, and cover the hillocks with manure. These, if the crowns are strong, give the finest Kale of the season. After that time the green seedy shoots of the plants, if cut just before they open when about 1 foot high, and if the weather has been warm and showery, are a good substitute for Asparagus; but if the weather has been cold and dry, these will not be worth the trouble of cutting on account of their bitter taste when cooked. Respecting Seakale being bitter I always think that it is either due to its being kept in too dry an atmosphere, or its not growing fast enough. I have never heard any complaints when it is grown under favourable conditions.

Those who have not grown the "Lily White" variety, as it is mostly called, should start at once, as I find that a great improvement on the old purple-tipped both in appearance and quality. This kind if forced well comes out quite white. The seed is offered in nearly every catalogue. A pint or quart will cover a large space of ground if sown carefully in rows about 18 inches apart, and dropping two or three seeds every 12 inches you can make sure of one good plant in each space if the seed is good. With attention during the season to hoeing, there will be some strong crowns for forcing. These if wanted for November should be taken up about the second or third week in September or the beginning of October, and laid in some rather dry soil for three or four weeks to allow the leaves to part freely from the crowns before planting in the boxes for forcing. Before these are placed in they should have the roots shortened, and all the strongest saved, and sets made for next year's supply. These should be made at the same time as cut off, as it is often very difficult to tell the top from the bottom if left till afterwards. I find a good way to distinguish the sets is to cut the top end square and the bottom on the slant, and at the same time to reject all damaged or worm or grub-eaten parts, and save nothing but clean pieces for planting. Lay these in shallow boxes of dry sand till spring, and if kept moist enough to prevent their shrivelling they will be found to be callused over by planting time. Plant in rows 12 to 18 inches apart, and from 6 to 12 inches between the sets according to their size. The earliest forced crowns if examined carefully and treated the same way as for the sets make good plants for forcing next year.

I find Seakale will not succeed if planted on the same ground every year, and if fresh ground is well trenched the plants will well repay for the extra care and trouble. A slight sprinkling of salt once or twice during the season will greatly assist the growth, as well as afford a check to weeds.—G. E., near Warwick.

NOTES ON FRUIT TREES—APPLES.

(Continued from page 259.)

LARGE CULTURE OR TREES ON CRAB STOCKS.

Espaliers.—Early: Royal Codlin. Midseason: Yorkshire Beauty, Alfriston, Beauty of Kent, Emperor Alexander, Golden Noble, Warner's King, Lord Derby, Hornmead Pearmain, Tower of Glamis, Melrose, The Queen, and Sandringham must not be excluded. Late: Bramley's Seedling, Annie Elizabeth, Rymer, Hambledon Deux Ans.

For Walls or Fences.—Beauty of Kent, Emperor Alexander, Hollandbury, Peasgood's Nonesuch, Castle Major, Lord Derby, Yorkshire Beauty, Melrose, Warner's King, Lane's Prince Albert, The Queen, Sandringham. For low walls or fences they must be grown on Paradise stocks. Grown on east to south and westerly aspects these varieties will afford magnificent fruit, and will be the talk of the kitchen if allowed to go there for any purpose beyond baking, and the marvel of the street if they make their appearance in fruiterers' shop windows.

Standards.—Early: Keswick Codlin, Cellini, Ecklinville Seedling. Midseason: Alfriston, Beauty of Kent (does not succeed on heavy wet soils), Castle Major (similar remarks apply to this as the preceding), Emperor Alexander, Golden Noble, Nelson Codlin, Yorkshire Beauty, Lord Derby, Tower of Glamis, Bedfordshire Foundling, Yorkshire Greening. Loddington may be put in the

same category with Blenheim Pippin—viz., it does not bear when young, but after it becomes aged—i.e., twelve to fifteen years old it is one of the most reliable and best. Late: Annie Elizabeth, Bramley's Seedling, Dumelow's Seedling, Rymer, Galloway Pippin, Gooseberry Apple, Hambledon Deux Ans, Hanwell Souring, Minchull Crab, Northern Greening.

Perhaps the greatest difficulty that besets the grower is the extensive number of varieties, many of which are of first class quality for their respective purpose, and the difficulty is further increased by the diversity of opinion respecting them. The most extensive growers and experienced pomologists find it no easy matter to reduce the number of first class Apples. All making a study of Apples form prejudices, even against their better judgment, which had become fixed by heredity and environment, so that they cannot through prepossession part with favourites, which, surpassing their compeers in some esteemed excellence, it may be of quality without any other characteristic of value are not befitting the times. Some for instance recommend Hawthornden as a kitchen and Ribston Pippin as a dessert variety of the highest excellence, which no one questions, but the fact respecting them is one may ride a horse to death before we find a healthy and profitable tree of either. Gems they may be of the first water when perfect, but the majority of investors in Apples look more at their easy term of purchase than at their high quality. It suffices for the masses if an Apple is of general usefulness—a combination of good appearance, quality, and practical utility. The grower, too, must cast aside his prepossessions and prejudices. What served our forefathers will not serve the present generation. There is a want—a market—and that must be supplied by the home grower, or it will be supplied by the enterprise and energy of the growers of other lands. It is no use blinking the fact—viz., our produce is not the best and cheapest put in the market. Decrying imported Apples will never make better grow in English orchards. What is required is effort guided by common judgment. The cultivator must expand his ideas of manufacture, get all the beauty, all the quality, and all the utility of the at one time costly article into the cheap. To effect this prepossessions and prejudices must in all matters outside be laid aside. Hardness of fruit, freedom and constancy of bearing will largely influence growers in making selections, to which there is nothing more to add only that the fruit be such as to command the markets. This will be best secured, not by an infinity of variety, but by growing few varieties in quantity, a number of trees of the most profitable kinds.

In making selection of what I consider the most profitable sorts it is not expected that they may have proved such in all localities; but if those taking exception to any will only name others they have found surpassing them in certainty, production, and profitability of crop we may form an estimate of their suitability for general culture. Six varieties for dessert and kitchen use—Lady Sudeley, King of the Pippins, Harvey Apple (Dr. Harvey, Golden Noble, Waltham Abbey Seedling), Rhode Island Greening, King of Tomkins County, Dutch Mignonne. To those add Reinette de Canada in warm, and Lemon Pippin in ordinary situations.

Six other varieties for dessert and kitchen use.—Harvey's Wiltshire Defiance, Baxter's Pearmain, Annie Elizabeth, Royal or Herefordshire Pearmain, Hormead Pearmain, London Pippin. Extra.—Hambledon Deux Ans.

Blenheim Pippin from its shy bearing in a young state is omitted. It may be planted by those that can wait with complacency its coming of age (twenty-one years), and then it is not a great or certain cropper. Probably a substitute may be found in Cobham or Golden Ducat, an early and good bearer, with quality equal, if not surpassing, Blenheim Pippin, and a better keeper.

Six varieties for dessert and kitchen use requiring good soil and sheltered or warm situations.—Washington, American Mother, Melon Apple, Northern Spy, Reinette de Canada, and Calville Malin. Extra.—Boston Russet.

Six varieties for dessert.—Irish Peach, Cobham or Golden Ducat, Cox's Orange Pippin, Cockle Pippin, Court Pendu Plat, Allen's Everlasting. Extra.—Stamford Pippin.

Six other varieties for dessert.—Kerry Pippin, Fearn's Pippin, Claygate Pearmain, Adam's Pearmain, Golden Reinette, Scarlet Nonpareil. Extra.—Golden Russet.

Six varieties for appearance and usefulness.—Yorkshire Beauty, Lord Derby, Dr. Hogg, The Queen, Sandringham, Lane's Prince Albert. Extra.—Emperor Alexander.

Twelve varieties for kitchen.—Keswick Codlin, Lord Suffield, Cellini, Alfriston, Beauty of Kent, Nelson Codlin, Galloway Pippin, Round Winter Nonesuch, Flanders Pippin, Bramley's Seedling, Dumelow's Seedling, and Northern Greening. Extra.—Mère de Ménage, Stone or Loddington.

Twelve other varieties for kitchen.—Potts's Seedling, Ecklinville Seedling, Bedfordshire Foundling, Betty Geeson, Grenadier, Tower of Glamis, Melrose, Yorkshire Greening, Murfitt's Seedling,

Rymer or Caldwell, Gooseberry Apple, Hanwell's Souring, Minchull Crab. Extra.—Warner's King, Niton House (a large, later form of Stirling Castle).

The selection comprises seventy varieties, which may be considered far too many, but if the first six of the dessert and kitchen, dessert, appearance and usefulness, and first twelve of the kitchen varieties with their respective extras are taken, the number is reduced to thirty-five, to which can be added Blenheim Pippin and New or Improved Bess Pool in the case of those that can afford to wait. Thirty-six or seven may be considered too many, but taking into account that a supply is required of useable fruit for not less than nine months of the year, it is matter of extreme difficulty to limit the kinds so as to make sure of an unbroken succession. The varieties differ in time and duration, and constitution or adaptability for location, being influenced to a considerable extent thereby, so that it becomes necessary to provide for contingencies, and in selecting provide accordingly.

Twenty-four varieties.—Keswick Codlin, Lady Sudeley, Lord Derby, King of the Pippins, Yorkshire Beauty, Harvey Apple (Golden Noble), Grenadier, Cox's Orange Pippin, Alfriston, Fearn's Pippin, The Queen, Baxter's Pearmain, Sandringham, Adam's Pearmain, Beauty of Kent, Flanders Pippin, Dr. Hogg, Lane's Prince Albert, Dumelow's Seedling, Round Winter Nonesuch, Bramley's Seedling, Annie Elizabeth, Dutch Mignonne, and Northern Greening. Amongst those will be found fruit suited to all tastes, for which, however, there is no accounting, as difference seems to follow variety, therefore add Rhode Island Greening and King of Tomkins County.

Twelve varieties.—Lady Sudeley, King of the Pippins, Yorkshire Beauty, Baxter's Pearmain, Cox's Orange Pippin, Grenadier, Sandringham, Flanders Pippin, Dumelow's Seedling, Dr. Hogg, King of Tomkins County, and Northern Greening, with Bramley's Seedling. The last may be substituted for Dumelow's Seedling where it cankers, and have a place in all selections of culinary Apples.

Six varieties.—Lady Sudeley, Harvey Apple, Sandringham, Bramley Seedling, Dr. Hogg, and King of Tomkins County.

Four varieties: Lady Sudeley, Harvey Apple, Dr. Hogg, King of Tomkins County.

Three varieties: Lady Sudeley (August to September), Harvey Apple (October to December), Dr. Hogg (November to April).

To the six, four, and three add Cox's Orange Pippin, and where the demand is greater for a dessert than culinary variety replace Harvey Apple by King of the Pippins. Cox's Orange Pippin and Reinette de Canada are perhaps not excelled, but they require good soil and warm situation.

Exception may be taken to Lady Sudeley, King of Tomkins County, Dr. Hogg, The Queen, Sandringham, and Lane's Prince Albert as not sufficiently proven, but if healthy growth, early and full cropping go for anything it shows their adaptation for dwarf and standard culture. Looking askance at varieties of demonstrated merit only causes the "plums" of the markets to fall into the lap of importers. Clinging to antiquated varieties causes the something that was going to be done to be put off indefinitely; indeed, we cannot find heart to cast aside the "baby" dessert kinds and the "crabs" of the culinary sorts, yet we complain of those investing in the full grown examples of other lands. Surely those bringing bullion to the mint have the first right to the coinage, therefore let us plant Lady Sudeley, Dr. Hogg, Lane's Prince Albert, The Queen, Sandringham, King of Tomkins County, with Alfriston, Yorkshire Beauty, Lord Derby, Golden Noble, Beauty of Kent, Wiltshire Defiance, having a line in the centre of Cox's Orange Pippin and Reinette de Canada alternately, and to keep guard around King of the Pippins, Bramley's Seedling, and Northern Greening. Then we may leave Blenheim Pippin and Bess Pool as a legacy to the times—the generation yet to come.—G. ABBEY.

(To be continued.)

GARDEN NOTES IN 1889.

GLADIOLI.

ALTHOUGH I have occasionally alluded to the Gladiolus during the past year, and especially in my report on those at the Crystal Palace Show in September, I have not entered into any details as I have usually done with regard to my own culture—notes which I find interest a good many who, like myself, can grow only a selection, my beds not containing more than about 500 corms, and I am so narrowed by space that I can only change my ground once in two years. I have other parts in my garden where they might possibly grow, but the soil is not so suitable as that is where I grow them and have grown them for some years; but although I can only give them this change, yet by cropping the ground with vegetables I think that a sufficient change is afforded them. Thus the beds where I am going to place them this year had Onions and

Potatoes last year. They were thoroughly well cultivated, and the ground well worked, so that it was in a very good state of preparation. The beds had been well dug in the autumn, and the manure dug in. It was more than once forked over during the winter, and thus thoroughly well exposed to the influence of frost. The beds as usual were 4 feet in width, thus allowing for four rows in each bed.

Previous to planting I have an overhauling of my labels, for although I enter the roots in a garden book according as they are run on the beds, and thus by a species of double entry to provide against mistakes, I have a very great objection to getting names misplaced, and although I am not likely to have anyone dropping down upon me, saying "That is all wrong," yet I am quite as particular as if such an event might take place at any time; for indeed, as far as the knowledge of anyone who enters my garden is concerned, I might call them anything I liked. When about to plant I take the corms of any one variety, examine them carefully, and where their size admits of it, I cut them in halves, leaving an eye to each half. This is a somewhat tedious process, as it involves (with me) the stripping off the outer coat of the corm, in order to ascertain where the eyes are, or else one might cut right through them. This practice commends itself to me more and more. I find that smaller corms than I used to think suitable for the operation may be so treated. I like it because it at once doubles the stock and secures two blooms instead of one. I this year did what I have long since abandoned, left a few of my corms in paper bags, and, as a result, I found that several of them had started, and when they had done so I found one eye dormant, and had the corm been planted whole, I believe that first shoot would have given the other but little chance. I cut it in two, and the dormant eye is now beginning to assert itself. I believe that smaller corms than one has been in the habit of considering suitable for the purpose may be cut, but those who have not adopted this practice will be perhaps content with dividing only the large ones.

The corms and labels being all ready I draw a drill the entire length of the bed, and about 6 inches in depth, so that when covered in the top of the corm is about 4 inches from the surface. I used at one time to use sand largely in planting, placing some round each corm, but I have given this up. We are in the habit in this neighbourhood of preparing wood for charcoal, to be used in the Hop oasts for drying the Hops. The wood is placed in lumps and surrounded with sand, and then burned. As only the large lumps are used for the purpose of drying there is always a quantity of fine powdered charcoal mixed with burnt sand left, and I have used this to surround the corms with, and find it very useful. When the corms of a certain quantity and variety are planted the label (I use one of about 10 inches) is placed, and then the next variety is planted. When the whole row is finished the second drill is drawn, the earth taken out by the hoe falling over the first one. When the whole bed is planted the earth is levelled down and then left. I did not in any way deviate from this, my usual practice, last year. I had a good bloom, but, as I have already said, not so good as in some previous years. We had not any spring frosts in May to injure, as I believe they sometimes do, the young shoots; but we had a very cold July and August, and I cannot but think the plants received a check, then many of the flowering stems came crooked, thus rendering the spikes utterly unfit for exhibition. I do not think that I shall trouble myself much about protecting blooms for this purpose. I did so last season, and I do not believe I exhibited more than one or two of those thus protected, yet there can be no doubt it is the best way to secure pure and untinted blooms, especially of the white varieties.

I had a difficult time in harvesting the corms. They like a dry warm autumn, and this is the reason why they do so well at Fontainebleau, and I may say at Cambridge; but when I say that we had nearly 8 inches of rain in October it may be well imagined that harvesting was a matter of some difficulty, the corms get so saturated with moisture that they look large and plump, but it is found when stored that they shrivel very much. I found too, that there was the same sort of season at Fontainebleau, and that Messrs. Souillard & Brunelet state that their harvesting was a very long and unpleasant one owing to the continuous rains.

I received from Mr. Allen of New York a dozen roots of American seedlings, of which he appeared to think very highly, and for the opportunity of growing them I was much obliged; but I am sorry to say my estimate of them did not accord with his, and I was not disposed to keep any of them as named sorts, and so they were all thrown into mixture. I had, as usual, some of the newer French varieties, but not those of 1888, and there are some of them that I find of very excellent quality. We want now flowers that will open well together, that show a good front (no blooms sideways), and now having obtained these size is sought for, and blooms are now to be seen, such as were never dreamed of years ago. The best of the French flowers of 1887 are:—

Arrière Garde.—Large flowers, rose salmon flamed with violet, creamy yellow blotches.

Aurore de Feu.—Clear rose, passing to scarlet, with golden yellow centre, fresh brilliant colour.

Docteur Bailly.—Very large open flowers, brilliant fiery red, small carmine blotches on white ground; a very striking flower.

Erigone.—Magnificent flowers, white ground, largely striped with rosy carmine, large rich carmine blotches.

Formosa.—A very beautiful early flowering variety, soft satiny rose slightly striped with carmine red.

Panama.—Very large flower of great breadth, deep carmine rose flushed with scarlet, and slightly edged with slate colour.

Picador.—Brilliant scarlet flower with pure white blotches.

Mr. Burrell of Cambridge has raised some fine varieties. Amongst them was *Avalanche*, a long spike of white flowers opening well together; *The Mikado*, a very brilliant scarlet flower; *Cygnets*, a creamy white flower, very pretty; *Mrs. Lendull*, a striped flower somewhat in the way of *Dobbie*, only much finer. All these I have grown. Not only are they good in themselves, but they are, I believe, the forerunners of some more fine flowers.

In reference to planting, I would advise all who wish to grow Gladioli well to take advantage of fine weather, and only plant when the ground is in a suitable condition. More harm than good is done when the corms are put into close and "stodgy" soil.—D., *Deal*.

NARCISSUS COUNTESS OF ANNESLEY.

FROM time to time during the past six weeks Mr. Baylor Hartland of Cork has sent us flowers of this variety. The earlier examples were

FIG. 35.—NARCISSUS COUNTESS OF ANNESLEY.

comparatively small, perhaps the produce of small bulbs, but the later flowers were quite as large as the figure supplied by Mr. Hartland, and we think more attractive than there represented. The trumpet is of a pure glossy yellow, and the perianth segments sulphur. The large flowers had a massive and hooded appearance, and were pleasantly fragrant. The variety appears to have been discovered in the garden of Lord Annesley at Castletwellan. Unfortunately, Mr. Hartland says the stock has got a little mixed, but, properly "rogued," he does not think there is a more vigorous or better market flower in cultivation. The variety appears to be spreading, as we find it was represented at the great quinquennial show of bulbous plants at Haarlem.

CURIOUS SEEDS.

I SEND you a small box containing a few seeds of a *Euphorbia* which we received last July from one of our Mexican correspondents. If you will keep them a moment in your hand you will notice that

they are alive, and on placing them on a flat surface the seeds will hop or leap in a very curious manner. There is not the least trace of any aperture in the seeds, but when cutting one it is found to contain a white maggot very vivacious, which will at once shut itself up again. They are called in Spanish the Devil's seeds.

An insect punctures the young ovary, deposits its eggs, and then the microscopical larvæ enter easily. The tissues close again, and soon shut up the small gallery without the slightest external appearance. The larva develops itself in the seed, and when mature the insect comes out. When fully transformed it deposits eggs again on the young ovaries. I cut several seeds during the winter, and always found the insects well alive, leaping and ready to obstruct the opening at once. The seeds jumped violently when we received them last summer, but at present they seem to have lost a little of their strength. It appears that the same curiosity has been noticed, although rarely, with the *Tamarindus*. I add a seed with a hole, from which the larva has escaped, as also the larva itself. Is not this a wonderful seed, and did you ever see its like?—E. SCHÆTTEL, *Vilmorin-Andrieux & Cie, Quai de la Mégisserie, Paris*.

[The seeds are somewhat triangular in shape, and not unlike wedges cut from large Peas. They went through the dancing performance very satisfactorily though not violently. We have only once before seen seeds of the same kind. They are decided curiosities.]

CATTLEYA TRIANÆ.

As these cease flowering remove them to the warmest end of the house, which should not be allowed to fall below 60° during the night, with a rise from 5° to 15° during the day. The stage upon which the plants are stood should be kept moist by damping amongst the pots frequently. If the pots or pans used are not of the ordinary type, but have numbers of holes round the sides, be careful not to get the compost too wet through syringing amongst them. A little more water will be needed at their roots, but on no account give too much. The supply must be carefully and gradually increased as the plants make roots and extend their growth. Water 10° warmer than the temperature of the house should be used when it is required either at their roots or over their foliage. The plants may with advantage be dewed with the syringe on the mornings of fine days. Air should be admitted during mild bright days, so that any moisture which lodges about the growths of the plants may be evaporated daily. Keep the ventilators closed when the air is cold, so that sharp currents are prevented reaching the plants.

TOP-DRESSING.

Plants that were potted last year may be top-dressed before they commence forming young roots. Sphagnum moss that has been used near the surface should be carefully picked and fresh supplied in a living state. It is wise to place this so that it can be readily removed annually. If the peat used was good none of it will need removal; a few lumps of fresh may be necessary to complete the work of top-dressing. These are often necessary as well as a few pieces of charcoal where the rhizome of the last growth is some distance from the compost.

POTTING.

Pots are decidedly the best for Cattleyas, although they do fairly well on blocks and in baskets suspended from the roof where stage room is limited. The pots to be used should be about one-third filled with drainage carefully arranged. The pots in which they are growing must be broken, because the roots cling tenaciously to the sides. The portions of pot should be carefully placed in the pots that are to be used for them. Some of these often rest upon the bottom of the pot, and in this case crooks must be carefully arranged amongst and about them until ample drainage has been placed in. Above these a few lumps of charcoal may be used, or better still, mixed in with lumps of good fibry peat about the size of an egg, until the remaining space in the pot has been filled. The surface should be completed with lumps of peat and living sphagnum alternately. The plants must be well elevated above the rim, and all decayed material removed from the old ball. If the material is sweet and in good condition it may be necessary only to remove the sphagnum moss. When the peat is good to commence with it lasts much longer for these plants than is the case with many Orchids. This is due to their requiring consider-

ably less water than many species. If the old material is decayed it should be removed, which with care may be done without injury to the roots to any serious extent. It must be remembered that if they are destroyed or damaged this season's growth will suffer. Plants that undergo this operation need the most careful attention in watering afterwards. If the compost becomes wet before active roots are working it will be found at the end of the season that the pseudo-bulbs have decreased materially in size, and the plants will have a yellow sickly hue.

BACK BREAKS.

Well-established plants may be induced to break back, or increase the number of their buds by cutting partially through the rhizome just in front of a plump dormant eye. Some care is needed not to cut too far through the rhizome, and thus stop supplies for the support of a portion of the plant. It may happen that the portion behind where the rhizome has been cut may have no active roots. Once a new growth has been made and a good quantity of roots, no harm is done in cutting the rhizome completely through. By this process it is often possible to increase the number of leads on a plant from one to three or four. As a rule these dormant eyes do not make strong flowering pseudo-bulbs the first season, but if the plants are healthy and well established they will often make strong growth the first season and flower.

SHADING ODONTOGLOSSUMS.

If the blinds have not been arranged on the roof of the structures in which these plants are grown, no time should be lost in fixing them. A little shade will now be necessary to screen the plants from bright sunshine, but on no account overshadow them at this early period of the season. Blinds should only be used on the side where the sun strikes with force from 11 A.M. to 2 P.M. It will not be necessary to draw the blinds down earlier, and the sun after 2 will do no harm. The supply of moisture in the atmosphere may be increased, but be careful not to saturate it. A low temperature and too much moisture will cause the leaves of *Masdevallias* to become spotted. Less artificial heat will be needed, but it should not be dispensed with altogether. The temperature may often fall too low at night. When there is every appearance of a fine day, the pipe valves may be closed in the morning.—ORCHID GROWER.

THE BRITISH FRUIT GROWERS' ASSOCIATION.

LECTURE AT ELLESMERE.

UNDER the auspices of the Ellesmere Horticultural Society (Salop), the above Association made arrangements for a lecture by Mr. John Wright on "Fruit Culture in Britain," and a meeting to be held in the Town Hall, Ellesmere, on Saturday, March 22nd. As briefly noted last week there was a large attendance of the leading agriculturists in the district, Brownlow R. C. Tower, Hon. Sec. of the local Society, presiding. The following abstract of a report appearing in the *Salopian and Montgomeryshire Post*, March 29th, gives an outline of the business and substance of the lecture.

The CHAIRMAN, who was most cordially received, in opening the meeting said that at a meeting of the Ellesmere Floral and Horticultural Society held not long ago, it was decided to take steps for the encouragement of and improvement in the culture of fruit in the district which the Society occupied, and he was requested to write to the British Fruit Growers' Association and ask them if they could kindly send down a lecturer or lecturers to address a meeting in Ellesmere as soon as possible. The Association very kindly consented to oblige them, and they had sent down three able representatives of the Association. (Applause.) They had Mr. Wright, who had written a very excellent hook called "Profitable Fruit Growing." He called it a book, but it was really a prize essay, an essay which won the gold medal presented by the Lord Mayor of London. Then they had Mr. Bunyard of Maidstone, and Mr. Baillie of Chester. The subject of fruit growing was one which he thought would interest them all, especially as their neighbourhood was better adapted for the growth of fruit than many others in the country. The growth of fruit in that district had declined within the last half century very considerably. They very seldom saw an orchard round about properly taken care of, or old trees removed and fresh trees planted, and now was the time when they had to turn their attention to every possible method by which a little money could be made. They were favoured with a good district, and it seemed a pity that they should not try to make the best use of what was given to them. (Hear, hear, and applause.) There were many small holdings and cottage gardens which if they were better planted with fruit trees might be vastly improved, and become a source of income to the people and wealth to the country. There were many millions of bushels of fruit imported into this country, and many thousands of pounds spent on imported fruit, and a great deal of it might be grown by ourselves. It was with the object of stirring up the district that the Ellesmere Floral and Horticultural Society had arranged for the lecture to-night, in the hope that it might be the means of giving an impetus again to fruit growing. (Hear, hear, and applause.)

MR. WRIGHT commenced his lecture by referring to the differing views that were entertained on the subject of fruit growing—the optimists, he said, regarding it as only another name for fortune-making, while the pessimists described it as all fudge, from which nothing could be gained. He thought the truth on this and other matters was to be found somewhere between extremities of assertion. He dealt somewhat trenchantly with persons who proclaimed their incapacity as cultivators by preaching in newspapers the doctrine of fabulous profits for all who would plant certain trees, and reminded his hearers that it was very necessary to beware of quacks. He directed attention to the action of the Royal Horticultural Society, the Fruiterers' Company, and the British Fruit Growers' Association in procuring and disseminating information with the object of increasing and improving the fruit supplies of the kingdom as altogether more reliable than the preaching of popularity-hunting crusaders. He pointed out the unwisdom of trusting to any one kind of fruit alone, such as Apples or Pears, for producing profitable crops yearly, and adduced instances showing that losses had been incurred by such ventures, especially when a tree each of a great number of varieties had been planted. He strongly advocated a directly opposite course—of planting many trees of a few of the best varieties, not omitting a due proportion of the more certain bearing small or bush fruits; and said that under the combination system he had never known a total failure, but on the contrary, with a good choice of sorts, good soil, and good management a fair return would accrue to cultivators and much better than they could obtain from farm crops. He would not, however, advise inexperienced persons to invest all their money in fruit growing, and thought farmers should only regard it as an adjunct to other crops. He should like to see good collections of fruit well grown around the stately homes of England, both for supplying those homes with the rarest and choicest samples as well as for educational purposes, in showing the tenantry the varieties that would be the most remunerative to them.

Several examples of land being increased in value by fruit culture were given, and of the consequent higher rents obtained on the termination of tenancies. An extension of the best Kentish methods was advocated, and a distribution of production over a much wider area, as trees were often barren in one district and laden with fruit in another, it might be 200 or 300 miles north of London, through the later blossoming of the trees. The fallacy of the reiterated allegation of fruit to the value of £8,000,000 being imported annually that might be grown in this country was exposed, and it was because the statement had scarcely an approach to truth that there was such a wide field open for British cultivators, who were advised to adopt American methods in selection, culture, packing, and marketing, then the time would not be long in coming when our enterprising rivals would be beaten in our markets. After indicating the periods after planting at which different kinds of fruits become profitable, Mr. Wright gave practical hints on situations and shelter for trees, soil and its preparation, planting, pruning, and manuring, some of the more important manipulative points, including the arrangement of trees, being illustrated by large coloured drawings. As it is not easy to give a digest of this portion of the lecture a few citations are adduced:—

Situation and Shelter.—As far as is possible avoid damp hollows where fogs or mists are prevalent, no matter how rank the grass may grow and how rich the soil may be. Trees in such positions grow rapidly, often too luxuriantly, and the wood does not then ripen, while if it does, and blossoms expand, they will be in great jeopardy of destruction by frost. I had for many years two orchards under my eye in the same parish; one was in the water course of the district, the other on the ground about 100 feet higher. The bottom orchard consisted of splendid young trees that blossomed freely, but spring after spring the beautiful prospect of fruit was turned into desolation by the action of frost in the moisture-laden atmosphere, while the trees grown higher and drier escaped injury. The lower orchard has not, over a series of years, given anything approaching a profitable return, but the one above the fog line, so to say, has been highly remunerative. An extensive riverside plantation in Worcestershire has produced nothing but disappointment; another, not a quarter of a mile from it, on higher ground, has afforded rich harvests of fruit. Still, when practicable the other extreme of great exposure and bleakness should be avoided, for a little shelter such as that afforded by hills or trees is desirable, and especially from the south-west and north-east, for a keen driving easterly gale often nips the blossoms in spring, while a tornado from the other direction in autumn strips the trees of fruit.

Soil and its Preparation.—For practical purposes it is sufficient to know that land in condition to grow first-rate crops of Potatoes, Turnips, Wheat, and Clover will grow first-rate fruit. Light or sandy soil on gravel will not do so. It must be of a holding character, and perhaps the stronger it is, provided it can be brought into good tilth, the better. It must contain potash, phosphorus, lime, and soda, and it is because of the presence of these essentials that the crops above mentioned exceed the average in bulk and quality. When spade culture is employed double digging pays well if properly done. The right way is to break up the ground to a depth of 2 feet or thereabouts, keeping the best at the top and the poorer subsoil below, or only an inch or two of the latter should be mixed with the upper layer. The wrong way most decidedly is to bury all the top, or best, soil at the bottom of the trenches with a foot of the subsoil dug out of them. If land is prepared with horse power the subsoiler should follow the ordinary plough both lengthways and across the field. The land may be stirred in that way to a depth of 18 inches, the bulk of the best

being kept in the best position. A good tilth can then be secured with other implements in suitable weather. See that the land has good natural or artificial drainage. The water table should seldom rise higher than within 3 feet of the surface.

Choosing Trees.—Small clean, thrifty young trees of two seasons' growth from the buds or grafts with a plenitude of fibrous roots are not only cheaper but better than trees of twice the age and size with few roots. Trees may be studded all over with blossom buds, and perhaps bear a dozen or two of Apples or Pears the first season, but this abnormal productiveness does not deceive "old hands" in fruit culture, but only the young and inexperienced. Trees of this nature are the stunted prodigies of the fruit world, and can no more be made of substantial service than a stunted snappish little poodle can be trained into a valuable shepherd's dog or retriever. So-called cheap trees are often seen in markets with the roots as dry as hay, and the swelling buds shrinking in spring. Leave such trees severely alone. They may be the dearest of trees in the end, for many that do not die refuse to thrive, and not a few so obtained have proved untrue to name and inferior in variety. Of all the disappointments in culture few can be greater than growing trees for some years only to prove their worthlessness. The time thus lost can never be regained, and a bad variety occupies as much space and takes as much nutriment out of the land as does a good one. In buying trees always take particularly into account the characters and reputations of vendors. This, with natural trade competition, is the best guarantee purchasers can have for getting good value for money.

Planting.—The sooner fruit trees are planted after the leaves can be shaken off them the better. They will grow afterwards if moved, even when the buds are swelling in spring, provided the roots are kept moist when out of the ground, and the soil is in free working condition. At no season plant when the ground is in a wet sticky state. Cut off mutilated roots and jagged ends, then the wounds will heal quickly and produce new fibres. Spread the roots out straight, and do not cover them deeper than they were in the nursery, the earth mark on the stems being a line of guidance. Do not place manure either in contact with the roots or under them, but spread it on the surface of the soil over them, and for a foot beyond their extension, leaving it to decay. Do not check roots near the surface by deep digging, but encourage them by top-dressings of manure and vegetable refuse, especially in hot dry weather, for keeping the top soil moist. Roots will then multiply there and produce fruitful growth; if driven down to the poorer subsoil for moisture the resulting growth may be strong, but not productive.

Pruning.—This is a puzzling subject to not a few amateurs. There is no mystery about it, and the learned who would make one are perhaps not quite so learned as they seem. Broadly speaking, it is a question if more fruit has not been prevented than produced by the action of the knife. The principle to grasp is this: If there is a well balanced proportion between root growth and branch growth, and the branches are so thinly disposed that the sun's rays can pass between them, fruit buds will form plentifully. First, then, have a sufficient number of stout main branches for forming a tree, then thin to prevent overcrowding, instead of shortening the branches to create it, or the growths will be crowded or shaded and the leaves spoiled. Good leaves are manufacturers of fruit. Shoots may be shortened after planting, because the roots have been shortened in digging up, and the balance between the two for the time destroyed. We want to restore it as soon as we can, and as we cannot stretch out the broken roots to the length of the branches or shoots we cut back these to correspond with the roots. When an Apple or any other tree grows too luxuriantly in summer, cutting back the shoots in winter is simply followed by more and stronger growths, and so the combat between man and Nature may go on for a generation, and Nature will win in foreing growth. The branches of a strong-rooted tree, if kept thin and not shortened, will in time counteract the root power, form blossom buds, and bear fruit, weather and insects permitting; but if for special reasons the growth must be arrested and kept within certain bounds the roots must be shortened to an equal or a greater extent than the branches.

Insects.—These must be subdued, and not many can resist the effects of a soap and petroleum mixture made by dissolving 2 ozs. of soft soap and a teaspoonful of soda in a gallon of boiling water, stirring very briskly in at the same time a small wineglassful of petroleum, such as is burned in lamps. Applied at that strength in the evening, not in the morning, it does no injury to anything but insects, though if the leaves are wet when hot sun reaches them they are apt to be scorched. Some of the best trees known to me are well syringed with that mixture every winter, and are free from American blight, moss, and caterpillars, though it may not be equally effectual in districts where the latter greatly abound. The remedy then to apply is Paris green.

Manuring.—A word may be useful on manuring fruit trees. They are often too generously treated when young, and over-exuberant growth incited; while when exhausted by bearing, or impoverished soil, they are left to starve, or, in other words, are first jampered then neglected. All fruits contain more potash than any other substance in their composition, and simple mixture generally useful will be found in four parts, lbs. or cwt., of nitrate of potash (saltpetre), and superphosphate of lime, two parts of sulphate of lime (gypsum), and one part of common salt, this last to be excluded near the sea coast. But it is obviously wasteful to apply these or any other manure to feed weeds. These must be kept down, and hoeing the ground frequently will greatly promote the growth of fruit trees, bushes, and plants. In reference to applying manure a plain line of guidance is this:—If trees

make young growths 18 inches in length or more the soil is, generally speaking, rich enough; if they make less than a foot of growth a moderate dressing of manure is desirable; if less than 6 inches a liberal application is demanded. A moderate dressing means 2 ozs. of chemicals to each square yard of surface, a liberal one twice the quantity, and it must always be remembered that the best feeding roots of trees that have been left to forage for themselves are not near the stems, but at a distance from them at least equal to the length of the branches. The roots will not travel so far if they find what they need nearer home, and the first need is moisture in summer, hence the advantage of surface dressings of stable manure or vegetable refuse, though circumstances often prevent their application. Liquid manure given copiously is of enormous benefit to trees that need additional support, and many have been invigorated by the contents of cesspools, which may be applied at any time, even in winter.

The lecturer concluded:—One other aspect of the fruit question, and a most important one, remains to be noticed—namely, the result of an extension of planting. If this is considerable will not the supply of fruit soon exceed the demand? My answer to that question is this: It will be soon enough to consider the matter when 25,000 acres of the miserable unproductive orchards of this kingdom cease occupying the land they waste, and an equal extent of other land is occupied with thrifty trees of the best varieties. But why that particular acreage? Because it is equivalent to the Apples now imported. It is from every point of view better to grow that bulk of fruit than to buy it from distant lands, as the nation is now doing. Moreover, mouths are ever increasing; and further, a better supply of first-class home-grown fruit will create a greater demand, as is the case with all useful commodities. We have also to consider that educational agencies are at work that will result in fruit being more regarded as food than it is at the present time. If we do not meet the demand that will arise other nations will do so, notably our go-ahead kinsmen in the land of the west. Have we not a fair chance to compete successfully with them? Land is about or quite as cheap here as it is in America, where the best fruit is grown. The average productiveness of cultivated land is much greater here than there, as is conclusively shown by the Wheat averages—ours being above 29 bushels, theirs being less than 19 bushels per acre. Labour is much cheaper here than there. They have hotter summers that make the fruit drier, and colder winters that often kill the trees; but they have better and more systematic methods. Their fruit culture is garden culture, so must ours be. Given this, with careful handling, sorting, and proper marketing, we shall regain our lost supremacy as a fruit-producing nation, enhance the value of land, increase the field of employment for workmen, and afford our populations what we do not afford them now—a full supply, a good supply, a wholesome and enjoyable supply of the purest food that can be produced—fruit, home-grown well-grown British fruit. Let us all join heartily and intelligently in this most worthy endeavour, and we shall not fail.

Mr. BAILLIE of Chester emphasised many of the points referred to by Mr. Wright, and said that if people that were fruit growers, or intended to commence the cultivation of fruit, were to follow the advice they would not be misled. He said good land, good trees, and good management were the secret of production. The people, too, wanted educating as to the value of fruit as food, for he thought it a shame that fruit should so seldom be seen on the tables of the people, except the wealthier classes. He pointed out that half an acre of land would produce £20 worth of fruit per annum, and said he knew many men near Chester who, with a garden attached to their cottage, more than cleared their rent out of it. (Applause.)

Mr. BUNYARD gave some most instructive hints to the gardeners present on fruit growing, which were listened to with great attention.

The Rev. O. M. FEILDEN proposed a vote of thanks to the speakers for their excellent addresses, which was responded to by Mr. BAILLIE, who concluded by moving a vote of thanks to the Chairman, remarking that such gentlemen as Mr. Tower were just the class of people to introduce fruit growing in a district.

The CHAIRMAN, in response, said he was in favour of fruit growing, and would do all he could to encourage it in this district. He advised all tenants to make arrangements with their landlords before commencing to plant fruit trees, feeling sure there would be practically no difficulty in their doing so in most cases. Speaking on behalf of Lord Brownlow, he was quite ready to enter into arrangements which he believed would be satisfactory to the tenants on the Bridgewater estate.

NOTES AND COMMENTS.

ARALIA SIEBOLDI.—Next to the Aspidistra I know of no other plant to equal the above for house decoration. It is surprising how long it can be kept in close rooms without injury if carefully watered and kept free from dust. Anyone who has a hotbed at command can soon raise a stock if they do not care to invest in a few plants, but like many other specialities in the hands of the nurserymen it is cheaper in the end to purchase a few plants, as the cost is but little.

NICOTIANA AFFINIS.—Regarding the note by your correspondent, Mr. W. J. Murphy, Clonmel, in reference to the plants grown by him, I hope it may prove to be a dwarf variety, as it would be very serviceable for pot culture. The finest effect I have seen produced by being planted outdoors was at Lyons, the residence of Lord Cloncurry, where the gardener, Mr. Down, had planted a border, the back line of which was formed of Gladiolus in mixed varieties. The Nicotiana was next to

the Gladiolus. The two front rows were Pelargonium Henry Jacoby, edged with blue Lobelia.

BEDDING BEGONIAS.—Anyone in the neighbourhood of Dublin in August or September who wishes to see these in their glory should pay a visit to the above named garden. None but the best varieties are grown, and they are well arranged as regards colour and height. Mr. Down is very successful in the culture of this plant.

CELERIAC.—This vegetable, a stranger in many gardens, is well worth cultivation. Treated like Celery, with the exception of earthing, it gives but little trouble. Care should be taken that the ground is not too heavily manured, or the roots will be stringy and black in the centre.

BUDA KALE.—A very useful spring vegetable, especially if the winter has been severe. It defies all weather, and when properly cooked equals the best Cabbage grown.

CABBAGE.—Chou de Schweinfurt. Have any of the readers of the Journal grown this variety?

PEACH BUDS FALLING.—The main cause of this, I believe, is dryness at the roots. I remember some time ago reading an article by Mr. J. Groom, then gardener at Linton Park, strongly advocating judicious watering through the winter, and never allowing the borders to approach anything like dryness. The instructions referred to I had the opportunity of carrying out last winter with good results.

FREESIAS.—I can add little to the excellent article on the culture of these beautiful winter flowering bulbs by "W. S." I find they do better if potted deep and plunged in sifted coal ashes—in fact, by treating like the Roman Hyacinths I have been fairly successful. I prefer them to any Hyacinth. The best flowering bulb which I have ever seen had a branched spike with twenty-two buds. I find 5-inch pots are the most suitable size to grow them in, as they come in very useful for vases for room decoration.

SEED CATALOGUES.—As this subject has been written about before by abler pens than mine, I do not intend to add much to it. I have been looking through two catalogues of the leading seedsmen in England, and I find there are twenty-eight named varieties of Radishes. Is it not to be wondered that we are put to our wit's end which are the best sorts? If we had three varieties more we should then be able to send to table a different variety every day in the month. The time was when the French Breakfast variety held its own, and I do not think it can be surpassed when well grown.—R. RUSSELL, *Palmerstown*.

EVENTS OF THE WEEK.—The Easter holidays give a brief cessation from horticultural engagements, but the Royal Horticultural Society's meeting on Tuesday, April 8th, will call many back to business. The Fruit, Floral, and Orchid Committees will assemble as usual at twelve noon in the Drill Hall, James Street, Victoria Street, S.W., and at 3 P.M. Mr. W. Ingram of Belvoir Castle Gardens will give a lecture on "Spring Flower Gardening." The usual monthly dinner of the Horticultural Club will also be held on Tuesday at 6 P.M., when Mr. C. T. Druery will read a paper on "The Wonders of Fernland." On Thursday (to-day), April 3rd, the Linnean Society will meet at Burlington House at 8 P.M.

— THE WEATHER IN THE METROPOLITAN DISTRICT has during the past week been variable but fine. Saturday and Sunday were remarkable days, very clear, with a soft S.W. wind, a bright sun, and a high temperature for the season, rising above 60° in the shade on Sunday. The wind changed on Monday to E. and N.E., and it became much colder, but still clear and bright.

— THE WEATHER IN THE NORTH.—March 24th-31st. Alternate bright and dull days have marked the past week; 2° frost on the morning of the 24th, and 3° last night. Saturday was the most unpleasant day of the week, with high gusty wind and pelting showers from the west. Sunday was as enjoyable as the preceding day was disagreeable, and the last day of March was also fine.—B. D.

— THE WILDSMITH MEMORIAL FUND.—We are desired to state that the total amount received up to March 26th, as contributions to the above fund, was £91 9s. 6d. Further subscriptions are earnestly solicited to raise the sum required for the proposed purpose. They may be sent either to Mr. T. Turton, Maiden Erlegh Gardens, Reading, Hon. Secretary; or to Mr. A. W. Sutton, Reading, or Mr. H. J. Veitch, Chelsea, Hon. Treasurers of the fund.

— CROCUSES AND SNOWDROPS.—There have been of late several articles on early Snowdrops and Crocuses, but, like many other plants,

earliness without lateness is incomplete. I have a late Crocus, of dwarf habit, that comes into flower after all the others are past. The Crimean Snowdrop was the latest we had until a few years ago, but a seedling is later still. A clump of these in the same position as earlier sorts did not expand until the 24th of March. Its foliage seems more dwarf than its congeners, and I may say an acquisition, as Snowdrops for three months in the year must be.—W. T.

— ON MARCH 22nd MR. W. CAULDWELL of The Ivies, Wantage, Essex, died in his sixty-seventh year. The deceased was a well known florist who had given much attention to Primroses with other hardy plants, and we have had occasion several times to notice his productions.

— THE BRIGHTON AND HOVE CHRYSANTHEMUM SOCIETY Committee are compelled to change the dates of their Show from November 4th and 5th to the 11th and 12th, because the "Dome," &c., has been engaged for another special affair during the week we had fixed on. Will you be so good as to announce the alteration in your valuable paper?—MARK LONGHURST.

— SHREWSBURY FLORAL FÊTE.—The summer Show has been fixed for August 20th and 21st, and the schedule of prizes is advertised in our columns as ready. This Fête holds its own as one of the most successful in England. By the balance-sheet for 1889 we find that the receipts for the year were no less than £2430, and this, notwithstanding the Show was held on two of the rainiest days in the year, a perfect downpour prevailing nearly all the time, the profits of the year were about £250, and the visitors exceeded 40,000. The simultaneous visit of Her Majesty the Queen to Wales prevented many visitors being present from a district from which the Society usually draws a large number of visitors.

— FRUIT GROWING IN SCOTLAND.—Mr. Cecil H. Hooper writes :—"I was in Edinburgh last week to give a lecture on Fruit Farming to the students of the agricultural class of the University, and had the pleasure of visiting the Duke of Buccleuch's gardens. In the houses there were Peaches nearly as large as Walnuts, Grapes, Pines, and ripe Strawberries. They get their coals now at 11s. a ton, and generally nearer 9s., which is a great advantage, and I think must more than compensate for the greater heat we receive. During summer they receive longer sunlight. At Dalkeith the vegetation was as forward as at Swanley. Hawthorn was in leaf, and Pears were nearly opening their blooms. I visited Mr. Welsh's fruit farm near Edinburgh. He grows Morello Cherry as bushes largely, and Raspberries, tied in the form of arches to lines of wire. His Strawberries are grown in beds of three rows, then one row omitted for convenience in picking. He has shelter Apple fences, Gooseberries, Black, Red, and White Currants."

— INTERNATIONAL HORTICULTURAL EXHIBITION AT BERLIN.—A sixth circular has been issued relating to this Exhibition, from which we gather that a special Committee has been formed for the decorative section, as it is intended to make special efforts for showing the connection between horticulture and architecture in respect to the adornment of rooms, balconies, and winter gardens. Prizes will be given for the most worthy examples. The guarantee fund has reached 90,000 marks (about £4500). An important part of the Exhibition will be the scientific division, in which the co-operation of several scientific institutes is announced. It is expected that the exhibition of petrified plants will prove of special interest to many, and that the landscape gardening division will be of considerable extent. Season tickets may be had for the Exhibition on favourable terms. All information may be obtained from the Secretary, Berlin N., Invalidenstrasse 42.

— THE SPRING SHOW OF THE SHROPSHIRE HORTICULTURAL SOCIETY was held in the Music Hall, Shrewsbury, on March 27th. The morning was wet, but during the afternoon the weather improved, and the Show was crowded at times by the aristocracy of the district. In some of the classes the competition was not so keen as usual, but there was no falling off in the quality of the exhibits. The chief prize, £3, for twelve plants in bloom in 10-inch pots, was won by Mr. J. Lambert, gardener to Col. Wingfield, Onslow Hall, Shrewsbury. *Rhododendron fragrantissimum* was doubtlessly the finest plant in the Show. Mr. Farrant, gardener to Mrs. Jason, Abbey Forge, Shrewsbury, was second, *Plumbago coccinea superba* and *Clerodendron Balfourianum* being his best plants. In other classes the principal prizewinners were Messrs. Lambert; Murrell, Oldfield Nurseries, Shrewsbury; A. Darby; Thurtle, gardener to Mr. Phillips, The Mount, Shrewsbury; Burr; Myres, Sutton Lane, Nursery; Davis, Blunt, Dicksons (Limited) Chester, and Perkins, Coventry.

— CABBAGE AND BACON.—One hundred and ten thousand tons of Cabbages are estimated to be used in London yearly, and an average of a thousand pigs are said to be eaten in London daily.

— BOLTON AND DISTRICT CHRYSANTHEMUM SOCIETY.—I beg to remind you that the Committee have arranged for the fourth annual Show of this Society to take place on the 14th and 15th of November next.—JAMES HICKS, *Hon. Sec.*

— GARDENING APPOINTMENTS.—Mr. G. A. Bishop has been appointed head gardener to S. T. Mander, Esq., Wightwich Manor, Wolverhampton; the gardens attached to the new mansion are expected to be formed and furnished on a very complete scale. Mr. J. Tunnington, foreman, Ketton Hall Gardens, Stamford, has been appointed head gardener to Sir H. D. Ingleby, Bart., Ripley Castle, Yorkshire.

— APPLE BEAUTY OF HANTS.—There are some doubts about this variety being distinct. It resembles the Blenheim Pippin so much, both in shape, size, flavour, and general appearance of the fruit, that it is considered by many of our best pomologists to be a synonym of it. While admitting the great resemblance of the fruit the trees differ much in habit of growth and in precocity of fruiting. Beauty of Hants is a robust grower, branch erect, and the tree when properly pruned forms a handsome symmetrical pyramid; whereas Blenheim Pippin grown as a pyramid is loose in habit of growth, and more inclined to spread out than grow erect, and the trees take a much longer time to come into a free bearing state than the Beauty of Hants. I planted several trees of both varieties here twelve years ago. The trees of Beauty of Hants have been bearing good crops of fruit for the last six or seven years, and it was only last year that Blenheim Pippin began to bear for the first time, although the trees are a good size and in the best of health. The stock on which they are worked may have something to do with it. It is a free stock, but I cannot say whether they were raised from the wild Crab or the seeds of cider Apples.—A. PETTIGREW, *Cardiff*.

— HORTICULTURAL CLUB.—A house dinner of the Club took place on March 25th, when Mons. Henry de Vilmorin was the guest of the evening. There was a very full attendance of members, representing all classes of horticulture, to do honour to their distinguished guest. The chair, in the absence of Mr. John Lee, who was prevented by other engagements from being present, was taken by Dr. Hogg, a very old friend of Mons. de Vilmorin. There were present the Rev. W. Wilks, the Rev. F. H. Gall, Messrs. Shirley Hibberd, Bunyard, Walker, Jefferies, Lynch White, Arnold Moss, Northrup from Minneapolis, Minnesota; J. H. Veitch, Herbert J. Veitch, Morris, Crowley, A. F. Barron, Wheeler, Herbst, Prince, Cousens, Turner, &c. The health of the guest was proposed by Dr. Hogg, and responded to in graceful terms by Mons. de Vilmorin. Other toasts were also given. "The Other Visitors," for which Mr. Northrup returned thanks; "The Royal Horticultural Society," proposed by Mr. Shirley Hibberd; "The Chairman," proposed by Mr. Wilks. A most enjoyable evening was spent, and many hearty good wishes expressed for the prosperity of the Club.

— THE JAPANESE PLUM.—Referring to the Japanese Plums Mr. John Gelding writes to the *Sydney Morning Herald* :—"Mr. Walter Hill, late curator of the Brisbane Botanic Gardens, has forwarded to me a box of Japanese Plums. This species appears peculiarly adapted for cultivation in climates where the ordinary varieties of Plums refuse to produce fruit, and from Mr. Hill's account the variety is wonderfully prolific in all such districts. The fruit, which rather exceeds in size a well-grown specimen of the Orleans Plum, has a rich, dark elarct skin, the pulp when fairly ripe being about the colour of the Prickly Pear, and when fully ripe is of a deep beetroot colour. Respecting its flavour, the fruit appears more suitable for preserving than for dessert purpose; and as without doubt the species will grow and produce fruit well in any part of New South Wales, those who go in for fruit preserving should largely grow this Plum as, preserved either as a jelly or as a jam, its colour would form a very attractive feature. I should also say that as a vegetable colouring matter its use should be adopted for colouring confectionery, and even dull-looking jams. The trees are of quick growth, and any quantity can be obtained by cuttings when once a healthy tree is obtained."

— WARE AND DISTRICT MUTUAL IMPROVEMENT SOCIETY.—This Society has held two successful meetings during the past month. On the 11th inst., Mr. A. King in the chair, a paper on "Vine Cul-

ture" was submitted to the meeting by Mr. J. C. Parker, and evoked a capital discussion by Messrs. Riding, Gull, Alexander, King, Phillips, and Fulford. There was much diversity of opinion on many points. A vote of thanks to the essayist and Chairman terminated the meeting. On the 25th inst., the Rev. E. E. W. Kirkby in the chair, a practical paper on "Mushroom Culture" was read by Mr. E. Wallis. Mushrooms were exhibited by Messrs. Bray and Gilliams. A lengthy discussion followed by the following members—Messrs. Bray, Alexander, Riding, Durrant, Phillips, Brown, and Fulford. A hearty vote of thanks was accorded the essayist for his excellent paper, and a similar compliment to the Chairman for his services concluded the meeting. The Committee are more than satisfied with the progress made by the Society since its birth, but there are plenty of gardeners and their assistants within easy reach of the meetings that do not attend. The Committee will be most happy to welcome them either as visitors or members. Any information will be gladly furnished by Mr. J. B. Riding, Hon. Sec., Ware.

— THE SPRING SHOW AT THE CRYSTAL PALACE, Sydenham, was held on Saturday last, March 29th, the principal classes being those for Grasses, Hyacinths, Lilies of the Valley, Mignonette, Cinerarias, Azaleas, Cyclamens, Tulips, and Narcissi, the non-competing exhibits comprising several large collections similar to those seen at preceding shows this season. Messrs. J. Laing & Sons, Forest Hill, won first honours with a capital group of Clivias, Azaleas, Orchids, and foliage plants. Messrs. H. Williams & Son, Finchley, were the principal exhibitors of bulbs, securing first prizes in several classes. Noteworthy exhibits also were the following:—Mignonette, from Mr. A. Carter Ewell Grove Gardens; Cinerarias, from Mr. J. Ford, Wexham Park Gardens; Amaryllises, from Messrs. Paul & Son, Cheshunt; Azaleas, from Mr. R. Wells, Sydenham; Cyclamens, from St. George's Nursery Company; Narcissi and Hyacinths, from Mr. Shoesmith; and Tulips from Mr. W. Clarke. Among the non-competing exhibits Messrs. B. S. Williams & Son, Upper Holloway, had a handsome group of bulbs and forced plants; Messrs. Paul & Son contributing a collection of Roses in pots and hardy flowers, and Messrs. Barr & Son a collection of Daffodils.

— BOURNEMOUTH GARDENERS' ASSOCIATION.—The fortnightly meeting of this Society was held on Wednesday, March 19th, at No. 4, The Quadrant. Mr. W. J. Ward, gardener, Kempsey, presided, and in a few words introduced Miss C. A. Rooper, The Tines, Bournemouth, who read a most interesting and instructive paper on the history of the Daisy. Miss Rooper, by the aid of well executed diagrams, and also specimens of fossils, which had laid in the bowels of the earth for countless ages, traced the history of the vegetable kingdom from prehistoric times until it assumed its present form, and showed how the little Daisy plays a most important part in the vegetable world. The Chairman, in the name of the members, thanked Miss Rooper for her valuable paper, and for the kindly interest which she takes in the Society. Miss Rooper in reply thanked the members for their hearty reception, and in the name of her father, the Rev. W. H. Rooper, presented to the library of the Society Mr. Wm. Paul's work on Roses, entitled the "Rose Garden." Other works on gardening were presented by E. L. M. Colville, Esq., Kempsey, Mr. J. J. Swaffield, and Mr. W. Watts, nurserymen. A vote of thanks to the Chairman concluded the meeting.

— A PAPER ON FORESTRY IN INDIA and the Colonies was read recently by Dr. W. Schlich before the Royal Colonial Institute. He said that for 700 years a gradual destruction of the forests of India had gone on. Under British rule the process had been hastened by the extension of cultivated and pasture land, and by the laying down of railways. After a time difficulty was experienced in meeting demands for timber, and in the early part of the century a timber agency was established on the west coast, while, in 1873, a teak plantation on a large scale was made at Nilambur. Through the energy of a few officials the matter was kept before the public, and in 1882 the Forests Department of Madras was entirely reorganised. Several Acts were passed to provide for the management of the forests under the protection of the State, and a competent staff of officers was provided, to be reinforced from time to time by those educated at Cooper's Hill College. Under the charge of the Department were some 55,000,000 acres of forest lands, and the figures relating to the cost of the work done were very satisfactory. Dr. Schlich then gave an account of the action of the Australian Colonies with regard to the regulation of wooded lands by the State, contending that in no case had sufficient steps been taken to ensure a lasting and continuous supply of timber.—(Nature.)

— GARDENERS' ORPHAN FUND.—At a meeting of the Committee, held on Friday evening last, payments of the following sums were announced:—Mr. English, as the proceeds of a concert, £5; Mr. L. Castle, by sale of books, £5; H. Pears, Esq., of soap fame, £5; G. S. Foljambe, Esq., £5; Mr. Roupell, proceeds of lecture, £6; benefit from Covent Garden Theatre, £10 19s. 6d. The Secretary expressed a hope that supporters of the Fund would favour by sending their subscriptions as early as possible. A cheque for £61 15s. was signed for the quarterly payments to children. Mr. L. Castle was appointed local Secretary for the Merton and Tooting district. Mr. T. Turton, Maiden Erlegh, Reading, signified his acceptance of the position rendered vacant by the death of Mr. Wildsmith. Mr. H. Divers, on his return from Florida, resumes his position as local Secretary for Ketton and surrounding district; and Mr. J. Trevor, Hatley St. George, was appointed local Secretary for Malvern. The Committee were glad to find that substantial progress was being made in the Wildsmith Memorial Fund, and trusted the £30 or £40 still needed to provide for the maintenance of a child would soon be forthcoming. The amount collected is referred to in a preceding note. In respect to the Floral Fête, to be held in the great wholesale flower market at Covent Garden on May 21st, a letter from the Mansion House announced the willingness of the Lady Mayoress to open the Exhibition. Tickets of admission will be the same as last year, 5s. each. A sub-Committee was appointed for making the necessary arrangements for what is hoped will be one of the most brilliant gatherings of the season.

— WE have received a copy of "CARTER'S PRACTICAL GARDENER," which has now reached the fourteenth edition, giving the book, we are informed, a circulation of over 100,000 copies. New, and as may be expected, good articles on Chrysanthemums by Mr. E. Molyneux, on Cucumbers by Mr. A. Pettigrew, and on Tomatoes by Mr. W. Iggulden are included, and the whole work revised and brought up to date. It is generally pronounced "a marvellous shilling's worth."

— THE CATERPILLAR PLAGUE.—Fruit growers will no doubt in many instances be astonished to learn that the winter moth's eggs are now hatching out rapidly in the orchards. I found an odd caterpillar on the 18th of March, but on the 27th a number of newly hatched ones were discovered. When first hatched they are so small that only those with good eyesight can discover them. Miss Ormerod recommends half a pound of Paris green to fifty gallons of water (keeping the mixture constantly stirred) as a spray for destroying the newly hatched pests. In a few days we shall give it a trial, and I hope it will prove effectual. During the past two months we have hatched eggs on shoots in our earliest Peach houses, and tried many experiments for dealing with the plague; but so far I cannot chronicle any real success, as it is far easier to kill the shoots than the insects. A few Apple trees in pots were placed in the latest vinery in the middle of January. In a short time eggs commenced hatching, and though the trees were carefully looked over daily by my employer and I we could not prevent the caterpillars spoiling most of the blooms. I believe that we have tried nearly all known insecticides (except Paris green), and also every other means that we could think of, all of which are more or less unsatisfactory, though we have destroyed millions of eggs by killing the female winter moth by hand on the trees (dwarfs) and cutting off and burning pieces infested with eggs. In time I have no doubt we shall be able to master these pests of fruit trees, but in the meantime it is very uphill and discouraging work. Perhaps it may be possible to syringe the trees in autumn with some composition that would prove offensive to the moths, and prevent their depositing eggs on them. Grease bands are of only slight value, as I have caught the male and female flying together as high as I could reach, the male having sufficient power to convey the nearly wingless female into the trees. Since writing the above we have had several degrees of frost, but the caterpillars seem to have received no injury, though newly hatched.—S. T. WRIGHT, *Glewston Court Gardens*.

THE HENDRE, MONMOUTH.

THIS beautiful place is the residence of J. A. Rolls, Esq., and is situated about four miles from the ancient town of Monmouth, which has greatly benefited by the munificence and generosity of Mr. Rolls. In the Jubilee year he built and presented to the town a very fine hall, and which is highly appreciated by the inhabitants. The road from Monmouth to The Hendre was formerly a heavy one, abounding in steep hills. This has been vastly improved, some of the hills having been lowered, or, where that was not possible, new roads have been made; thus not only benefiting the public generally, but finding employment for the working class during the winter months when work is scarce.

No doubt many a poor man's family would have suffered want if it had not been for Mr. Rolls' liberality in providing employment. On passing through a pretty lodge, the house and gardens are approached by a serpentine drive through a well-wooded and extensive park, which must be very attractive in summer. The gardener's house is pleasantly situated, looking into the park on one side and into the gardens on the other. On reaching it a most hearty welcome was received from Mr. and Mrs. Coomber, and as time was limited, an almost immediate adjournment was made into the houses. The first house we entered contained some splendid Queen Pines, showing grand fruits—in fact every one was good. Mr. Coomber, who has had charge here for sixteen years, never has a Pine moved after it is placed into the fruiting-size pot, as he justly remarked it is almost impossible to move them about without some little injury. That the practice answers is amply demonstrated by the plants. Pines in other divisions are the picture of health and good management. Queens appear to predominate, but Smooth Cayenne and Charlotte Rothschild are also extensively grown.

Leaving the Pine stoves, a range of vineries was next entered. The first division contains late Vines just beginning to break strongly and regularly. The next is an early house, in which the Vines are in grand order, and though forced early for many years, the growth and foliage are remarkably fine, and a heavy crop of large and shapely bunches are hanging. The last division is planted with various kinds, all commencing to break well. Gros Maroc is particularly strong. Alnwick Seedling also is well worthy of notice. Some find this a difficult Grape to set well. Mr. Coomber's plan may be of service to them. When in full bloom the bunches are syringed to wash off the glucose matter, and the next day are fertilised with pollen from another variety. Under this treatment no difficulty has been experienced in securing a good set. Passing into other houses, Melons, Cucumbers, and Tomatoes are all in fine health and promise good results. At the back of these is a house containing some extraordinary large Calanthes, many of C. Veitchi being a foot or more long in the bulb, and other kinds equally fine. Entering the kitchen garden, another range of vineries and Peach houses run along the walls. These vineries have been planted recently with young Vines in inside borders, the old Vines being planted outside, and will probably remain till the young ones require most of the room. Both the young and the old Vines look very promising, but with the heavy soil here, inside borders will prove the most satisfactory. The early Peach trees have set a heavy crop of fruits, which are now about stoning. The other houses contain trees from those mentioned down to others coming into bloom. In the whole long range every tree is carrying or promising good crops of fruit, and without exception are models of high cultivation. Strawberries are forced extensively, about 1600 plants being grown. When the plants are put in to force, a square piece of turf is placed under each pot, which is better than saucers, as the water can pass away freely and at the same time supply a moist medium for the roots to run into. A new house has just been erected for forcing Strawberries, from plans proposed by Mr. Coomber, and I think it is the best for the purpose I ever saw. It is span roof, with tiers of shelves running lengthways of the house one above another, from the eaves to the ridge, thus placing all the plants close to the glass. Watering is done from the under side of the shelves, the plan being very convenient, as the plants can be reached for any purpose.

The plant houses are all filled with well grown and useful plants. The first house contained at the front a very strong and healthy collection of Chrysanthemums, consisting of all the newest and best varieties, principally grown for producing large blooms. At the back a large quantity of Lachenalia tricolor were a mass of bloom; it is seldom that these beautiful plants are seen so finely grown as here. The next house was filled chiefly with Orchids. Cypripediums appeared to be in great variety, some of the plants being very large, the old C. insigne being grown in quantity and well. A fine plant of C. Spicerianum was also conspicuous, and many smaller Cypripediums in choice variety. Cymbidium eburneum was blooming profusely, and Cattleyas, Coelogynes, Dendrobiums, Trichoplias, and Lælias are all excellent, and no doubt a fine collection will soon be established. Another house is devoted to plants for decorative purposes, all clean, bright and healthy. In one of the houses some really magnificent Eucharises are grown. Most of the plants are of enormous size, and throw up immense quantities of bloom. Carnations are largely grown, as they are not only very useful for cutting, but they travel well in sending to the family. At the back of the plant houses a small case is occupied by Filmy Ferns, Todea superba being particularly fine, but all receiving treatment that evidently suits them well. A little further on is an orchard house filled with Plums, Pears, and Apples, all promising to carry good crops.

The conservatory is adjoining the houses, and is a large and lofty structure, well filled with Palms, Ferns, Pandanus, climbers, &c. Lygodium scandens is much liked as a climber; every year it is cut down to the soil, and the way the young growths are coming up again proves how well the system answers. One side has a well arranged rockery, and by the aid of water is rendered very effective. Many rare and beautiful plants cannot be mentioned, as time was flying fast, and no notes could be taken. The shrubberies and pleasure grounds are kept in the best of order, not a weed to be seen anywhere, neatness and good order prevailing in all departments. The kitchen garden is highly cultivated, and lies well to the sun. Great credit is due to Mr. Coomber for his success in every part of his charge, as the soil is of a very heavy nature, and requires a good deal of judgment and careful management. To commemorate the Jubilee year a new and commodious bothy was erected for the young men. Both Mr. Rolls and Mr. Coomber evidently

desire to make everyone happy, contented, and comfortable on the place. Long life and prosperity to them and all belonging to them.—S. T. W.

PRUNUS PISSARDI.

THOUGH the above named Prunus is chiefly known and valued for its richly coloured foliage, it is also useful for early flowering under glass, and in this way is now employed in some gardens. The flowers are white, or with a faint tinge of pink. They are produced most abundantly, and in contrast with the dark coppery leaves just appearing, they look extremely well. The tree is of slender, graceful habit,

FIG. 36.—PRUNUS PISSARDI.

and seems to be well adapted for culture in pots. It is readily forced, and lasts for some weeks.

The spray figured was supplied from Mr. A. H. Smee's garden at The Grange, Wallington, where it is prized for its useful qualities; and the gardener, Mr. Cummins, speaks highly of it for decorative purposes. When the leaves are fully expanded out of doors the tree has a striking effect amongst green leaved or variegated shrubs, the colour being a distinct reddish or coppery bronze—quite a metallic tint. It does not appear to be particular as to soil or situation.

CULTIVATION AND SELECTION OF POPULAR ORCHIDS.

BY MR. ALEXANDER WRIGHT.

[Prize Essay, Chiswick Gardeners' Mutual Improvement Association.]

ORCHIDS have of late years become such favourites with most plant lovers that it is important the gardener should have a good knowledge, not only of their culture, but the selection of the most popular and

useful kinds suitable for home decoration. That selection is no easy matter becomes apparent when we call to mind the great number of Orchids now known, numbering, according to different authorities, from 3000 to 6000 species.

By "popular Orchids" I mean those that are most appreciated by the general public, admired for the beauty or fragrance of their flowers alone, and not for their money value. The high prices realised by some of the varieties that have appeared amongst imported plants have helped, to a large extent, to draw the attention of plant lovers to this quaint and varied family. And it is curious to notice that once the attention is drawn to Orchids, and their beautiful and curious flowers are examined, the more one sees of them the greater is the desire to know more about them. Whether this may be owing to the diverse shape and size of some of the flowers, to the rich and various colours to be found amongst them, or the delicious perfumes given off by some of the flowers, or all combined, I am not prepared to say; but certain it is there is a great fascination in Orchid flowers and in Orchid growing, and the passion expands as though destined to become universal. In no class of plants do we find mimicry carried to a greater extent than in Orchids. Here we may see rude representations of the bee, the butterfly, the dove, the swan, beetles and flies, and even man himself is not omitted from the range of resemblances.

In colour the most fastidious in taste can be pleased, as nearly all colours and shades are to be met with in Orchid flowers. The perfume of the flowers is varied; in some species it is most pleasing, and in others so strong—or, as some people I know put it, so offensive—that it is best inhaled at a distance. When we consider we have all those advantages combined in one class of plant, it is not surprising to find that their culture is increasing year by year by "leaps and bounds," as their treatment and requirements become better understood.

We often hear it said we "kill our favourites with kindness." In no class of plants does this apply with more force than with Orchids. There have been more Orchids killed by attempting to grow them in a too hot and dry atmosphere than all other causes combined. This, to a large extent, may be the fault of the plant collector in the first place, who may find some plants in a tropical country, and in sending them home forget to say they were found growing so many thousand feet up on a mountain side, in a cool and moist temperature, or whether they were found growing in the valley below, where the atmosphere was both hotter and drier. This, unfortunately, may be considered one of "the secrets of the trade," to prevent other collectors discovering the locality where certain species or varieties are to be found. Whatever may be said to the contrary, I consider that to know the native habitat of a plant and its surroundings must be a guide to a certain extent to its successful cultivation, although it would not always be correct to conclude that the conditions were everything the plant desired, but rather the conditions were the best to be had under the circumstances.

When the cultivator has no reliable information of a plant's natural habitat to guide him in its culture on its first introduction, often many plants are lost until a mode of treatment is found under which they will grow and thrive. But we are living in an age of rapid progress, and let me say, to the credit of gardeners generally, that when once they discover the cultural requirements of any plant that has been found difficult to establish and grow, there are few amongst them but would let it be known for the benefit of their fellow workers. Possibly in no other class of men will you find this kind and friendly spirit so freely carried out as you will amongst gardeners. With this friendly spirit so prevalent, and with the aid of the horticultural press, any difficulty in plant growing once understood and explained, soon the information spreads throughout the length and breadth of the land, and all are benefited by the publicity.

The cultivation of Orchids in private gardens is often carried on under great difficulties, either as regards the houses they have to be grown in not being of suitable construction, or having to grow them along with other plants. Yet we often meet with examples of successful culture where Orchids have to be grown with a miscellaneous collection of stove plants, and many of the grand collections of Orchids now to be met with throughout the country were first started in this way. Where Orchids have to be grown with other stove or intermediate house plants, as we often find them in places where there are no houses devoted entirely to their culture, it will be found advisable to keep the plants as well up to the light as possible, and away from the dry air coming direct from the hot-water pipes. It will be found that growing the plants in baskets suspended from the roof of the house, where the house is large and the plants would be a considerable distance away

from the glass if left on the stage, is one of the best ways to obtain satisfactory results. Most of the epiphytal Orchids will be found amenable to this treatment, and where the house is lofty it is surprising what can be done to add to its attraction in this way. Where the plants are kept near the glass as here recommended, it will be found that they will grow better and bloom more freely than plants grown further from the light, and with more substance in the flowers, consequently lasting a longer time in perfection.

If it is desirable to grow the Orchids in pots on the stage amongst other plants, and the stage of the house is made with the usual wooden battens, and the hot-water pipes underneath, it will be found a great advantage to fill in the open spaces, and cover with shell shingle, broken coke, or ashes, to retain the moisture amongst the plants when necessary, as will be the case during their growing season and the hot summer months.

Where Orchids are grown in quantity it will be necessary and of the utmost importance to have suitable houses, and the small span-roofed house running east and west has been found the most adapted for their requirements. For the culture of what are termed cool-house Orchids, a house not exceeding 12 feet wide will be found the most convenient, just allowing room for a path down the centre of the house, and side stages from 3 to 4 feet wide on either side. Some horticultural builders have adopted the system of double stages, but where water tanks are formed the length of the house on both sides the double stages are not at all necessary. For cool-house Orchids I would strongly recommend the formation of those tanks. It is not necessary they should be more than a few inches deep, with perhaps a deeper part about the middle of the house, to allow the dipping of a can for watering purposes. I am strongly in favour of the shallow tanks in preference to deeper ones, as they are more readily cleaned out. The stages should be kept well up to the light, yet leaving room for the plants to be stood on inverted pots, as this allows more room for using the syringe freely amongst the plants in damping down.

In the heating arrangements of the house there should be sufficient hot water to keep up the necessary temperature without having the pipes too hot. The ventilation of the house should be ample; there should be means of admitting plenty of air opposite the hot-water pipes, as well as at the ridge of the house. The question of air is a most important one in Orchid growing. To be a successful cultivator it will be found beneficial to have a plentiful circulation of fresh air amongst the plants, even when it is necessary to apply a little more fire heat to keep up the required temperature. I do not go so far as to advocate, as some growers do, the admission of cold air even when it is freezing sharp. I do not believe that air admitted under such circumstances is beneficial to the plants, but rather otherwise. If air is admitted at all other times the plants will suffer no ill effects by the house being closed at night during frosty weather. Again, in the neighbourhood of London, where fogs are so prevalent, a sharp look-out will have to be kept to guard against them finding an easy entrance into the houses. The houses should be closed on its first appearance, otherwise the effect of a dense fog will be most disastrous to the flowers and flower buds, causing them to wither up and drop wholesale. Some species are found more liable to the injurious effects of the fogs than others. The *Phalænopsis*, *Calanthes*, *Dendrobiums*, *Lælias*, and *Oncidiums* flowering during the autumn and winter months suffer to a larger extent than perhaps any other genera.

Let us now turn our attention to the house just described, and see what may be done with it. Having agreed to adopt a minimum winter temperature of 50° to 55°, with a proportionate rise with sun heat during the day, and a minimum summer temperature of 60°, with the corresponding rise in the daytime, we will have a house in which a great many of the most beautiful of our popular Orchids may be successfully grown.

ODONTOGLOSSUMS.—Coming first on the list of popular Orchids would be *Odontoglossum crispum* (perhaps better known as *O. Alexandræ*), one of the most beautiful and useful of Orchids. This, along with its other varieties, will always form a very attractive feature in the house, for wherever a quantity of it is grown the house will seldom be without some plants in flower. Other *Odontoglossums* that would find a place amongst popular Orchids would be *Andersonianum*, *Cervantesi*, *Chestertoni*, *cirrhum*, *citrosimum*, *Edwardi*, *gloriosum*, *grande*, *Halli*, *Insleayi*, and its varieties, *splendens* and *leopardinum*, *luteo-purpureum*, *maculatum*, *Oerstedii*, *Pescatorei*, *Phalænopsis*, *pulchellum*, *Rossmajus*, *triumphans*, and *vexillarium* (this last at the warm end of the house).

Of **CYPRIPEDIUMS**, *Boxalli*, *barbatum* and its lovely varieties, *Harris-*

ianum, insigne, and varieties; Lecanum, Leeaenum superbum, Schlimii, venustum, villosum, &c.

Of ONCIDIUMS, dasystyle, Forbesi, incurvum, macranthum, Marshallianum, ornithorhynchum, tigrinum, varicosum, and Rogersi.

CATTLEAS, citrina, crispa, Lawrenceana, labiata, Gaskelliana, Mendeli, Mossiae, Skinneri, Trianae, and its pretty varieties.

LÆLIAS, alba, anceps, autumnalis, and varieties; Dayana purpurata and varieties.

EPIDENDRUMS atropurpureum, fragrans, vitellinum majus.

DENDROBIUMS, Ainsworthi, crassinode, Devonianum, aureum, nobile, Pierardi, thyrsiflorum, and Wardianum.

ADA aurantiaca.

AUGULOA eburnea, Clowesi.

CÆLOGYNE cristata and its varieties.

CYMBIDIUM eburneum, Lowianum, Mastersi.

LYCASTE Skinneri and its numerous varieties; aromatiea, citrina, plena.

MASDEVALLIA amabilis, Chelsoni, Chimæra, Harryana and varieties; ignea, Lindeni, and Veitchiana.

PLEIONE humilis, Lagenaria, maculata, and Wallichiana.

SOPHRONITIS grandiflora.

Some of the above species are not generally given as cool house Orchids, but in the temperature recommended above I have found them grow and flower satisfactorily. I have also omitted many of the beautiful named varieties of different species, but with them it is only the question about their price which keeps them from becoming popular.

(To be continued.)

HORTICULTURAL BUILDINGS AND HEATING APPARATUS.

[A paper read by Mr. Henry Hope, horticultural builder, at a meeting of Birmingham Gardeners' Association.]

(Continued from page 257.)

SOME very good examples of what I consider useful, as well as ornamental, conservatories are the following. To commence with an exceptionally large one, the conservatory at Enville Hall, Staffordshire, the seat of Lord Stamford, is a splendid example of a modern winter garden, and is certainly one of the finest in England. It is constructed of timber and iron, a very striking feature in the design being the glass cupolas in the roof, which have been used for placing large Azaleas in with a very good effect. The conservatory at Chatsworth, Derbyshire, is remarkable more for its size than for its beauty. A very architectural conservatory, and one of the most beautiful that has ever come under my notice, having a large amount of stone and marble in its construction, is the one at Witley Court, the seat of Lord Dudley. This also has a roof constructed entirely of iron and glass. To come nearer home, I consider the conservatory at The Dales, Edgbaston, designed by the same architect as the last two I have mentioned, is one of the best examples of an architectural conservatory in the midlands, and I think it would be hard to find a glass building with such good features in its design, and at the same time to admit such a large amount of light. The conservatory at Highbury, the residence of the Right Hon. Joseph Chamberlain, M.P., is one of the best examples I know of—a Gothic conservatory of wood construction—and in my opinion both for appearance and utility this form of conservatory is the most satisfactory; but of course the design of the dwelling house to which it is attached always dictates to a large extent the type of any glass building you wish to attach; and there is no doubt that if the architect in designing will consult the wishes of the gardener there is no reason why a conservatory in any position and under circumstances should not be built for appearance, utility, and unqualified success.

Of fruit growing houses there are a great variety, and for each sort a different form of house under different conditions will do equally well. To commence with vineries, these can either be span-roofed, three-quarter span-roofed, or lean-to, or curvilinear; better span-roofed or lean-to. The first thing to decide upon in the erection of a vinery, and indeed any form of house for fruit, is the site. Now if a wall is available for building against, this wall should run east and west, and the vinery should be placed on the side of it facing the south. If it is a plain lean-to it is obvious that during that part of the year that the sun rises north of the east and sets north of the west the vinery would, of course, lose part of both early morning and late afternoon sun. To do away with this objection a three-quarter span house should be erected, and I think I can safely say that this form of vinery in this position will give the best results.

CONSTRUCTION.

With regard to the construction, wood is now most generally used, metallic houses having lost their popularity to a great extent. There has been a great deal said with reference to the merits of iron versus wood houses. Metallic houses are said to be very cold, although admitting a large amount of light, and they are said to expand and contract to such a degree as to break the glass. Wood houses have none of these objections, but they cannot be made so lightly as to the timber of the rafters, sash bars, &c., as metallic ones. In my opinion, for fruit growing purposes especially, a properly constructed metallic house is as conducive to good results as a wooden one, but it must be constructed in the very best manner in framing, and sashes with light copper sash bars, and providing that the heating apparatus is perfect the only real objection of these I have named—viz., that of cold, is non-existent. Any breakage of glass from expansion and contraction is simply a *prima facie* proof that the house is wrongly constructed, and I may say that a badly constructed metallic house is the worst form of house possible, and the existence in many gardens of houses of the type has tended to a great degree to condemn metallic houses as a class. To sum up, I consider in the following points wooden houses are excelled by metallic ones. Kept properly painted their wear is everlasting, while wooden ones are always liable to rot. They admit 25 per cent. more light, and have a cleaner and neater appearance. To support these arguments I believe I am right in naming the following metallic vineries, and which I believe answer their purpose admirably. The houses at Frogmore and Osborne, the vineries at Arundel, the seat of the Duke of Norfolk; those at Impney Manor, Droitwich; Penrhyn Castle, Bangor; Elvaston Castle, Derbyshire; Drayton Manor, near Tamworth; Hemel Grange, near Bromgrove; and Barford Hall, Warwickshire, the late Miss Rylands'. Of course I am perfectly aware that many more examples of wooden vineries bearing quite as good results could be given, and there is no doubt that equally good Grapes can be grown in either sort of house by gardeners who understand and take an interest in their work.

For early work the pitch should be steeper than for late Vines. Curvilinear houses are no better than ordinary roofs for growing purposes, and the choice between the two is only a matter of taste for the appearance. The interior fittings are very simple, and really only consist of the wiring, which should be strong and placed at about an average of 18 inches from the glass. For growing on the lateral system the wires should be strained horizontally on iron bearers, and for the spur system should be strained up each rafter.

The ventilation should be by opening front lights when there are any, and in the roof by a light hinged at the apex, or in houses where there are no front lights ventilation through the wall is desirable. The pipes should be placed about 2 feet 6 inches from the front wall, so as not to be too close to the Vines.

The houses just described as suitable for Vines will, with appropriate interior fittings, do equally well for Peaches. I think the most approved form of wiring for Peaches is by a table trellis about 6 feet wide in the front of the house, and upright wiring for growing on the back wall. Peaches can be grown very well indeed without heat under wall covers, and of these structures a great variety are made, and from their extreme simplicity and comparatively inexpensive nature they are, in a good situation, a very profitable form of horticultural building. I have heard one gardener say that in a house 100 feet long he had grown enough fruit in three seasons to pay for the cost of the structure, and this without any artificial heat.

A very useful form of tree cover is about 4 to 6 feet wide, with upright fronts to the height of about 7 or 8 feet, according to the back wall, and the roof to be made entirely of opening lights hinged at the back wall to open by machinery in long lengths so as to give ample ventilation. The front should also be made in lights, so that they can be taken off easily to give thorough exposure to the trees after the crop of fruit has been gathered. A cheaper form of wall cover is by a lean-to structure, the glass running in one plane from the top of the back wall on to a dwarf front wall, with roof lights at the top to open as previously described. Others are made with a cant—i.e., the same as the first one I described, only having the front sloping slightly towards the back wall instead of being vertical. All I think answer their purpose equally well, and the adoption of any one is only a matter of choice. While discussing wall covers, I will refer to the question of mechanical glazing without putty, as I think it has been applied to this class of horticultural structure more than any other, chiefly on account of their simplicity, and the large quantity of straight bars and glass of one size in their construction.

There are many patent systems of glazing. Each one of these has its own particular merits for railway station roofs and other kindred structures, but I think at least some of them [are not sufficiently draught tight for early forcing in horticultural structures. I consider that for growing houses the glass should be bedded in putty and secured in its place with copper sprigs, the rebate being painted down two coats after glazing. For conservatories, where a heavy moulded sash bar can be used, a keyed bar with top putty has a better appearance; but it is no use top putting a sash bar unless it has a key to hold the putty in its place and prevent the wet getting behind it.

(To be continued.)

LANDSCAPE GARDENING.

[Read at a meeting of the Cardiff Gardeners' Association by Mr. Kettlewell.]

(Concluded from page 261.)

PERFECT walks and drives should be dry, smooth, and hard during every season and in all weathers, otherwise the proprietor may be robbed of a good deal of enjoyment, comfort, and exercise in his garden; thus the formation of walks is a most important part of the practical work of landscape gardening, and much of the pleasure of a garden will depend upon how the walks are formed. To make a walk dry, eyeholes with gratings on the top should be built every 30 to 50 feet, according to the size of the walk or drive, in order that the surface water may drain off into these, and thence by means of a small branch pipe or rubble drain into the nearest common drain. The centre of the walk should be slightly raised in order that the surface water may drain into the eyeholes, which are built at the lowest points of the walk. This will render the walk, if suitable materials are used, as mentioned above, dry in all weathers. The best materials for forming the sides and bottoms of these eyeholes or lodges for water are ordinary bricks or flat tiles.

In order to judge the width of a walk the size and arrangement of a garden must be taken into consideration, straight walks being always wider than curved ones. From 6 to 10 or 12 feet will be about the general width of straight walks, including terrace walks, while from 5 to 8 feet the average width of curved walks. Drives vary from 10 to 16 feet in width, according to their length and object. The materials for a walk or drive should be composed of coarse gravel, clinkers, or any angular material to the depth of 12 to 15 inches, and then fine gravel to the depth of 3 inches. The rough gravel should be well beaten before the fine gravel is laid down, and the whole well rolled. One word more as to the verges or edgings of a walk. These should consist of sods cut about 9 inches thick and 12 inches in length and breadth, and should be laid along the margins, allowing 2 or 3 inches to pare off the top, and a similar amount off the sides next the walk. They make at once an excellently firm edging, and after they are laid the ground can be easily levelled down to them.

We now pass on to drainage, which is perhaps the most important operation, and really one of the first on a new place. No enjoyment can be obtained on undrained land, no plant will thrive where the land is not dry and porous, while the sun is unable to penetrate and sufficiently warm the soil which is saturated with water. As warmth and air are essential to the roots of plants and trees, drainage is always of primary importance in a naturally damp soil. In garden land, as well as any other kind of land, deep drainage has been proved to be the best, as the roots of trees, shrubs, and vegetables strike down so far into the ground that shallow drains impede their progress. In a close retentive subsoil 4 feet, however, is quite deep enough for any drain, and where the subsoil is sandy 3 feet is amply sufficient. Parallel straight lines 15 feet apart have been recommended as the most suitable method of draining heavy garden land, and I have also seen land herring-boned very successfully—that is with a main drain running down the centre, and branch drains running into it at rather an acute angle. A good fall for the main drain is important on account of the amount of water it has to carry away, and a good outlet absolutely essential. Tiles or pipes are generally used for garden drainage, varying in size according to the amount of water they have to carry away. These pipes should have flat stones or slate placed underneath them, and their sides filled with rubble in order to keep them in the right position, while over the top an inverted sod should be placed in order to prevent the soil from working into the drain and disturbing the fall of water.

The last subject, on the practical treatment of which I should like

to say a few words, is on planting, or as Mr. Loudon calls it, "operating with wood." Operating with wood is, I think, above all other subjects the one, as I said in the beginning of my paper, which must be left to the good taste and skill of the true landscape gardener. As every place requires different treatment, rules and principles are impossible to the foreground of the picture. Before planting, the ground should be trenched all over, bearing in mind the fact that trees or shrubs can hardly have too rich a soil. When the trees and shrubs have had their places allotted to them and the holes, which should be wider in circumference than the roots of the tree, have been dug to receive them, the roots and fibres should be carefully examined, and where injured scrupulously pruned with a sharp knife. As every root has its corresponding share of branches and foliage to supply, so much mutilation of the roots will bring about a corresponding sickness and even death. Not only is much injury caused to a tree by removing it carelessly out of the ground, but also in its reinsertion into the ground, by reason of the crushed and huddled state of its roots and fibres. The utmost care, therefore, is necessary in replanting, that the roots and fibres be preserved and carefully spread out, covering them with light fine soil, carefully but firmly treading the ground above them when the soil has nearly all been put back again. In planting specimen trees, each one should stand on a little hillock from 6 inches to a foot high, as this plan has the advantage not only of throwing out the proportions of the plant better, but also of draining it better, and bringing the roots more within reach of air. As regards the best time of year for planting, it would be waste of time for me to tell you, as you all know the conditions under which the moving of trees or shrubs is most successful. I would only say, that without it was absolutely essential, I should never plant (1) if the sun were shining brightly, (2) if the atmosphere were dry, (3) if the ground were frosty. As to the selection of trees or shrubs I should take into consideration the nature of the subsoil where they are to be placed, and should endeavour as far as possible to obtain the plants from nurseries where they have been grown (1) in a poorer soil, (2) where they have been transplanted often, so that the plants should be well furnished with fibrous roots, hardy, and rather stunted in growth. These, when transplanted in a richer soil and under favourable conditions, will prove the most beautiful and perfect in shape and growth.

ROYAL HORTICULTURAL SOCIETY.

MARCH 25TH.

SCIENTIFIC COMMITTEE.—Present—D. Morris, Esq., in the chair; M. Henry de Vilmorin, ex-President Botanical Society of France; Messrs. Blandford, MacLachlan, Wilson, Rev. W. Wilks, and Dr. Masters.

Figs.—Branches were exhibited covered with a brown scale, which the sender said had proved very injurious. The remedy suggested was to scrub the branches with a hard brush and soapsuds. The specimens were further referred to Mr. MacLachlan for examination and report. Other branches of Fig in a dying condition were apparently free from parasites, and their condition betokened some mischief at the root.

Iris sindjarensis.—A plant of this was exhibited by Messrs. Barr and Son, and received a botanical certificate. M. de Vilmorin pointed out its resemblance to *Iris orchidacea*.

St. Helena Ebony.—Mr. Morris alluded to the peculiar vegetation of St. Helena, now confined, for the most part, to a small area in the central and higher part of the island. Many of the trees formerly native to the island are now all but, or quite, extinct. Among them is a species of *Trochetia*, or *Melhanian*. The trunks of this tree are embedded in the cliffs of the island, and are dug out by the inhabitants for the sake of manufacturing ornaments. The following quotations from Melliss' exhaustive work on St. Helena refers to this plant:—"The native Ebony of St. Helena.—This plant I believe to be now extinct. It formerly grew on the outer portions of the island, near the coast, at altitudes of 2 to 4, where the weather-beaten stems are still found deeply embedded in the surface soil. The last plant I saw was a small one growing in the garden at Oakbank, about twenty-five years ago, but it is not there now, and I have searched the whole island over for another, but in vain. The leaves were dark green, and the flowers white; the wood is very hard, heavy, black in colour, and extremely brittle. It is still collected and turned into ornaments, which are much prized on account of its rarity. That this tree once formed a considerable portion of the vegetation clothing the island on those parts that are now quite barren, is strongly evidenced by the many references to it in the local records. Pl. 29. It is the *Dombeya erythroxylon* of Andr., *Bot. Repos.* vi., t. 389, not of Willdenow."

It is interesting to know that the plant is still in existence under cultivation at Kew (and perhaps elsewhere) under the name of *Dombeya erythroxylon*. At the present time the plant, which was obtained from the gardens at Herrenhausen, is in flower at Kew.

Mr. MacLachlan called attention to the interesting remark on the rare plants of St. Helena, contained in Mr. Wollaston's book on the "Coleoptera of the Atlantic Islands."

Fingered Citrons.—Dr. Masters showed a drawing of a fruit that

had ripened in the garden of Mr. Hanbury at La Mortola, near Ventimiglia, and made some comments on the peculiarities of its structure. M. de Vilmorin said that similar malformations occurred in other Oranges, especially in the Bitter Orange, the flowers of which were used in perfumery, and in which the carpels might be seen occasionally in all stages of dissociation.

Sport of Narcissus.—From Mr. Walker came one bulb producing two distinct flowers—viz., Silver Phoenix and N. incomparabilis fl.-pl. The specimen was referred to Dr. Masters for further examination.

Florida Pine.—From Mr. Divers came a cone of *Pinus eubensis* (Elliott), and one of *P. inops* var. *clausa*, just brought home from Florida. Mr. Morris spoke of the wood of the Cuban Pine as being very hard, and said that many colonies were now importing soft wood, not that their own forests were destroyed, but because the timber yielded by them was too hard to be used profitably. M. de Vilmorin pointed out the difference between the typical *Pinus inops* and the specimen exhibited.

THE JAPAN QUINCE (CYDONIA OR PYRUS JAPONICA).

THE common scarlet flowering variety of the so-called Japan Quince is said to have been introduced into English gardens in 1815, and a few years later into those of this country. Authorities differ in their opinions as regards the proper position this plant should hold in the Rosaceæ, or great Rose family. Some consider it so nearly allied to the common Quince (*Cydonia vulgaris*) that it should be placed in the same genus; others believe it more nearly related to the Pear and Apple, hence should be classed among the *Pirus* or *Pyrus*, as both forms of spelling the word are about equally popular and common in botanical works and plant catalogues. But whatever its generic name, the Japan Quince must long remain a very popular ornamental shrub, increasing in the estimation of all lovers of showy plants as new varieties are introduced and disseminated. The first species or variety introduced from Japan has dark scarlet flowers, and it is probably the same one now most common in gardens. Later a variety with pale rose or pinkish flowers was introduced under the name of *Cydonia chinensis*, as it was supposed at the time to be a distinct species, and a native of China, but it is now known to be only a variety of the first, and not specifically distinct. Soon after a semi-double scarlet variety was introduced, and this is also common in nurseries and private gardens. For a number of years these three varieties were the only ones offered in nurserymen's catalogues, but in the past two decades a large number have been added to the list, and while the range in colour of the flowers is not so great as in some other genera of cultivated plants, still it is sufficient to warrant the assertion that the Japan Quince is one of the most showy and desirable deciduous shrubs in cultivation. They vary greatly in habit, but are mostly many-stemmed, thorny shrubs, growing 5 to 6 feet high. The flowers, as in the Apple and Pear, are produced on short spurs, growing from the stems and older branches, and rarely on wood less than two or three years old. The fruit of the species and older varieties is of a roundish form, about 1 inch in diameter, often ribbed or sutured, greenish yellow when ripe, very acid, flesh firm but with no grittiness, and agreeably perfumed. It has long been considered by pomologists as utterly worthless, and not edible even when cooked, but exceptions to this rule are known, and others are likely to occur as new varieties are produced. That the fruit is susceptible of great improvement is indicated in its variableness in the different varieties in cultivation. The habits of the plants are also variable; some are low-growing and dwarfish, others slender and upright; some are armed with an immense number of strong and sharp thorns; others are smooth stemmed and almost as free from them as a Willow. The great differences in the size of the fruit is shown in the following varieties:—No. 1 is from the common scarlet, while No. 2 is a medium-sized fruit of *C. grandiflora*, or the "large flowering." The flowers are pale pink, somewhat blotched with white. The plant is a low-growing shrub with a spreading habit, but wonderfully productive. Fruit when ripe, green, spotted with small pink dots. No. 3, Sunray, flower pure bright salmon colour, each petal with a smooth margin, and elevated from the calyx on a slender stem-like base, giving to the flower a deep cup-like shape. Fruit of the form shown, resembling in shape certain varieties of the Lemon. The skin is a deep lemon-yellow, without spots or blemishes, and feels to the touch as though it had been oiled. No. 4 is from an unnamed seedling with pink flowers, only remarkable on account of its russet fruit. The original plant produced about a half peck of fruit this season all of the same form and size, with skin thickly covered with dark brown russet. No. 5 is from a seedling of *grandiflora*, and while in habit of plant, colour, and size of flowers it is identical with its parent, still the fruit is distinct, and it is merely introduced here to show that the fruit is a character worthy of attention when attempting to distinguish closely related varieties.

Among these newer varieties the one known in some nurserymen's catalogues as *C. simplex alba* is perhaps the best white, as there is no tinge of colour in the flowers. *C. Maulei* is probably the best of the light scarlets. The fruit is very ornamental, as it assumes a bright golden colour long before it is mature. *C. tricolor* is a beautiful variegated-leaved variety with pale scarlet flowers, but unfortunately a feeble grower on its own roots, though moderately vigorous when grafted on Paradise Apple stocks. *C. Gaujardi* is a beautiful variety with orange-red flowers. The plant is of a low, spreading habit, with vigorous and almost thornless branches. Many other varieties are described in

nurserymen's catalogues, to which it is unnecessary to refer, for my object in writing is not so much to encourage the purchase of a great variety as it is to raise them from seed. With a half-dozen of the very best as stock plants, anyone so inclined can raise an unlimited number of varieties by annually saving and sowing the seed, and, when the plants are a year old, transplant into rows, and cultivate them as an ornamental hedge. It requires no great amount of skill or care to raise the seedlings, and there is always a chance of producing something better than is on the market, besides knowing that what you have raised is all your own, and that you are not greatly indebted to others for the plants, whether good or bad. All that is necessary to raise seedlings and new varieties is to gather the fruit when ripe in autumn, and spread it out in the house until it begins to shrivel and soften, then cut it open and remove the seeds. The seeds will, no doubt, grow if kept dry over winter, but my practice has been to take a large flower-pot or box with a hole in the bottom for drainage, then fill with seed and moist sand well mixed, after which bury the vessel on the north side of some building or hoard fence, covering about 1 foot deep. Early in spring sow the seed and sand together in drills in the garden. The plants will usually grow 6 to 12 inches high the first season, and the following spring they should be transplanted into nursery or hedge rows, and given the same cultivation as those raised from cuttings of the roots, layers, or other modes of propagation. Some of the plants may bloom the third season, others not until four or five years old, but whenever they do bloom we are sure to find some among them that will interest us. I have followed this mode of propagation of the Japan Quince for a number of years, and must confess that the results have been eminently satisfactory, for there seems to be no end to the variations in seedling plants. Should a unique and valuable variety be produced, it may be readily propagated by layers, cuttings of the wood and roots, or by budding and grafting upon Paradise Apple stocks, or those of our native Crab App'e. The common Pear and Apple appear to grow too rapidly, and the union is seldom perfect or very lasting, although there is no difficulty in making the wood of the Quince unite temporarily with either.—(*American Agriculturist*.)

GLASGOW SPRING SHOW.

THE spring Show of this Society was held in the City Hall on Wednesday, March 26th. The weather was not of the best, some heavy showers marring, as it always does, the attendance and consequent success of the Show from a financial point of view. The patronage under the circumstances, however, was very good, particularly in the afternoon and evening. The electric light is a vast improvement for showing the true colours of the flowers, such trying shades as blue and violet coming out as distinct as at noonday. What was wanted most was some greenery to tone down the great mass of colour with which the tables were loaded. Hyacinths were well shown, comparing favourably with former years. Nurserymen were represented by two collections of eighteen distinct varieties, Mr. John Sutherland having the best. The same exhibitor was also first for twelve table plants. Messrs. Smith & Simons were successful with hardy Rhododendrons. This firm had a large collection of spring flowering plants, especially Azaleas. The platform was decorated by the Messrs. Austin and McAslan. Spring flowering shrubs were well represented, and a few Orchids were included. Mrs. Paterson, Buchanan Street, was awarded a first class certificate of merit for floral exhibits of wreaths, baskets, bouquets, sprays, and crosses, a large Ionic cross being most artistic.

Mr. Hugh Millar, Auchendraith, Bothwell, had chief honours in the gardeners' class for Hyacinths, twelve distinct varieties, six being doubles. Mr. Carnegie, Gartshore Gardens, Kirkintilloch, was a good second in these classes, and had first for six singles. Mr. Hugh Millar had also the best *Cinerarias* and *Narcissus*. Tulips were admirably shown by Mr. Heron, Pollok Gardens, Pollokshaws, and this is the thirteenth year consecutively in which he has had the premier award. The only collection of plants came from Murcier House (gardener Mr. Geo. Meston), a first prize was deservedly awarded. Orchids were the best feature of this group, some *Dendrobiums* and *Odontoglossums* peeping out from a carpet of Maidenhair Ferns. Three collections of specimen Orchids were shown. Mr. D. McKenzie, Muirena Gardens, Cathcart, had first place for small but well flowered plants of *Cypripedium villosum*, *Cattleya Trianae*, and *Ceologyne cristata*. Mr. D. Wilson, Westmount, Kelvin-side, was second, having a well flowered plant of *Dendrobium nobile*, *Odontoglossum Edwardi* with three good spikes, and the beautiful *Cymbidium eburneum*. Mr. Geo. Meston was third, *Dendrobium crassinode Barberianum* being his best plant. Mr. Jas. Spiers, Violet Bank, Langside, had the best stove and greenhouse plants and specimen Azaleas, although these were not up to the standard of former years. Azaleas in 8-inch pots were creditably shown by Mr. Jas. Millar, Castlemilk Gardens, Rutherglen. Dinner table plants were largely shown, Mr. D. V. Agnew, Asgog, Bute, being an easy winner; his plants were splendidly coloured and medium in size, *Crotons Weissmani* and elegantissima, *Pandanus Veitchi*, *Aralia Veitchi*, *Dracena nigra rubra*, and *Cocos Weddelliana* were included. *Deutzias* were numerous and well grown; Mr. D. Wilson had the best specimen, a moderate sized but densely flowered plant. The best Palm, a fine plant of *Kentia Belmoreana*, came from the same gentleman. Mr. Jas. Millar, Castlemilk, had the best *Cyclamens*, and of the two collections of vegetables staged Mr. Millar's was decidedly the best. Alpines in pots are always admired when well done. Mr. Meiklem, Alpine Cottage, Bridge of Weir, had first prize with *Primula nivalis*;

P. viscosa, *Erica cernua*, *Chionodoxa Luciliae*. Baskets of spring flowering plants were shown packed very much as if they were going a long journey, the first prize basket of Mr. J. Millar excepted. Mr. J. Millar had also the first prize for *Amaryllis*.

In the gardeners' class hardy *Rhododendrons* were grandly shown by W. Carnegie, Gartshore Gardens, as were the cut trusses which came from the same gentleman. Amateurs made a creditable display, Mr. A. Blackley, High Blantyre, showing three greenhouse plants, one *Azalea*, one *Deutzia*, and gaining first in each of these classes. Mr. Meiklem, Bridge of Weir, had the best *Hyacinths* in pots. Miss M. B. McIntosh, 2, Firpark Terrace, Dennistown, had the best three *Hyacinths* grown entirely in water, and the best two pots of Dutch bulbs in bloom. In the class confined to ladies, Mrs. Carnegie, Gartshore, had the first honours, closely followed by Miss McIntosh and Miss Sutherland Lenzie.

Mr. Franc Gibb Dougall, superintended the arrangements, which were very satisfactory.—KELVINGROVE.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced Trees.*—Allow the trees time during the stoning process, maintaining the temperature at 60° to 65° at night, 70° to 75° by day with sun heat, and about 65° by day in dull weather, carefully avoiding sudden fluctuations or depressions. Tie the shoots to the trellis as they advance, and regulate the growths for future bearing, so as not to have them too crowded, as by giving the shoots plenty of room the fruit is better exposed to the sun and air, and the wood for another year is stouter and better ripened. Shoots disposed to grow more than 14 inches may have the points pinched out. Those remarks do not apply to extensions. When the stoning process is over, which may be ascertained by testing a few fruits with a knife, the fruit will require regulating for the swelling-off period. Very vigorous trees may be allowed to carry a few more than those that are weakly, but on no account unnecessarily tax the trees with more fruit than can be brought to maturity without prejudicing future crops. Weakly trees should be supplied with liquid manure, and the inside border in any case must be kept properly supplied with water, mulching the surface with partially decayed manure. This will secure more uniform moisture, and the fruit will swell to a good size. The temperature may be increased to 65° to 70° at night, and in the day 70° to 75°, maintaining 80° to 85° or 90° through the day from sun heat. Ventilate from 75°, and close early with plenty of atmospheric moisture. Very early varieties as *Alexander*, *Waterloo*, and *Early Beatrice* will soon give signs of ripening, when syringing must cease, and the leaves that shade the fruit or overhang it must be drawn aside, and the fruit if necessary raised on laths across the wires of the trellis, so that its apex will be placed directly to the light.

Trees Started at the New Year.—The fruit has swelled indifferently in some cases. Stoning will soon commence. Care should be taken to prevent sudden checks by injudicious ventilation, cold air in the daytime and too high a temperature at night being fatal. Rest content with a night temperature of 60° to 65°, 5° less on cold nights and 65° by day in dull weather, with 70° to 75° from sun heat. See that there is no deficiency of moisture in the borders; if it is at all dry afford a thorough supply of water or liquid manure.

Trees Started Early in February.—These, for some unaccountable reason, are later than usual, but the set and swelling are so far satisfactory. Syringing must be practised morning and afternoon, which will assist the trees to shed the remains of the flowers, and prevent attacks of red spider and aphides; but avoid heavy syringings, an occasional one being all that is needed until the foliage is more advanced. Allow a night temperature of 55° or 60° in mild weather, ventilating from 65°, permitting an advance from sun heat to 70° or 75°, but with full ventilation.

Disbudding.—This requires to be done with care and judgment, commencing early—as soon as the roots can be displaced with the finger, and be followed up day by day until only the shoots required for future bearing, attracting the sap to the fruits, or extension are retained—namely, one from the base of the shoots now fruiting and another on a level with or above the fruit; the latter not being required for extension should be stopped at a few joints of growth. In the case of trees not fully grown it will be necessary to leave shoots about 15 inches apart, calculating from the base on last year's growth to form the bearing wood of next year, the terminals being trained in their full length as space permits. Closer training is often practised, resulting in weak overcrowded growth, not nearly so satisfactory as growth fully exposed to light and air.

Thinning the Fruits.—Commence as soon as it is fairly set, removing the smallest first and those on the under side of the trellis, beginning with the weakest part of the trees, thinning proportionately less on

strong than on weak wood, which will tend to the equalisation of the vigour of the tree. The fruit ought not ultimately to be left closer than one to every square foot of trellis covered with growth, but Nectarines being a smaller fruit may have one to every 9 inches square of trellis covered by the trees. The first thinning should be commenced when the fruit is the size of horse beans, the second when the size of marbles, when very few more will be left than is required for the crop, looking over the trees again when the fruit is the size of walnuts, and very few indeed over the intended crop should be left, though there must always be a margin for casualties.

Syringing.—All the trees not in flower should be syringed twice a day when the weather is bright, so as to keep down red spider and other insect pests. The afternoon syringing should be done at closing time, so as to have the foliage dry or nearly so before night. If the trees have water hanging on them in the morning omit the afternoon syringing. This, however, will only be required with very vigorous trees. Allowing water to hang on the trees for any length of time destroys their tissue and has a weakening tendency.

Tying-in the Growths.—This should be attended to early, as it requires to be done carefully so as not to bring the shoots down too sharply, yet it is necessary that it be done; indeed, it is of the utmost importance where symmetrical training is considered, and in securing the shoots to the trellis sufficient space must be left in the ligatures for the swelling of the shoots.

Trees Started Early in March.—With trees in full flower syringing must cease; indeed, it should not be practised after the anthers show clear of the corolla, but a genial condition of the atmosphere should be secured by damping available surfaces in the morning and early afternoon. Prevent a close vitiated atmosphere by admitting a little air constantly by the top ventilators. The night temperature should be 50°, falling 5° or more through the night in severe weather, 50° to 55° by day and 65° from sun heat. The inside border must not lack moisture.

Latest Houses.—The flowers are opening, and as they are abundant thin them well on the under side of the shoots. Shake the trees daily from the first pollen ripening until the last of the blossom needs attention, selecting the early part of fine days where artificial impregnation is resorted to, and it is a capital plan to dust every blossom when the pollen is ripe with a camel's-hair brush, feather, or some other light substance. Any trees deficient of pollen should have some taken from those that afford it plentifully, as the small-flowered varieties usually do. The temperature should be maintained at 40° to 45° at night, 50° to 55° by day, in all cases accompanied by slight ventilation at the top of the house, which must be increased when the temperature reaches 50°, and full at 65°.

Unheated Houses.—The buds are fast expanding. Keep the house as cool as possible by free ventilation. Ventilate after the flowers expand, at 50°, and do not allow an advance above 65° without full ventilation both top and bottom, and close the house at 65° when there is a prospect of frost at night, but leave on a little air to allow of moisture escaping. In mild weather leave the ventilators open when the temperature is over 50°. Where there is a superabundance of flower buds remove those on the under side of the trellis.

FIGS.—*Earliest Forced Trees in Pots.*—The fruits of *Early Violet*, *Early Prolific*, and similar kinds will soon commence ripening, when the supply of water must be gradually reduced, and withhold moisture from the atmosphere, admitting air by the top lights constantly. Continue to afford liquid manure to those trees swelling their fruits, and syringe the trees at closing time, ventilating freely in favourable weather.

Early Forced Planted-out Trees.—No fruit tree produces surface roots so freely as the Fig if means are adopted to encourage them. A mulching of about 3 inches thickness of partially decayed manure will attract the roots to the surface, and prove beneficial if kept moist. Liberal supplies of water or liquid manure will be necessary to assist in swelling the fruits satisfactorily. Continue to pinch out the points of the shoots, and thin all crowded growths. No kind of tree is more benefited than the Fig by the full rays of the sun. Shading of any kind, even too much of their own foliage, is injurious. The temperature must now be increased to 60° to 65° at night, and in the daytime from 75° to 80° with sun heat. Attend to tying in the shoots, allowing space for growth.

Raising Young Trees.—If it be desired to increase the stock, cuttings may be inserted, selecting shoots about 6 inches long, taking them off with a heel or portion of last year's wood attached. They strike readily in bottom heat. They are best inserted singly in 3-inch pots. When rooted shift without much delay into 5-inch pots, and when they fill that size with roots transfer to 12-inch pots. Good drainage is necessary. Turfy loam with a sixth part of old mortar rubbish and a fifth of decayed manure forms a suitable compost, potting firmly.

KITCHEN GARDEN.

AUTUMN SOWN ONIONS.—The winter has been very favourable for these. Part of the young plants should be transplanted now, and the others left to bulb where they were sown. These will be the first ready for use, but the others will form the largest bulbs if grown in deep rich soil. Soot is beneficial to them and distasteful to grubs. We plant in rows 1 foot apart, and 4 inches from plant to plant, with the intention of pulling up every alternate one for use before they have gained their full size. After planting tread along each side of the row to make the soil firm, as this induces the plants to bulb early.

SOWING BROCCOLI.—Seed may now be sown of varieties that will give a succession from November until May. Veitch's Self-protecting Autumn is our earliest, Sutton's Queen the latest, and the intermediate consist of Osborn's, Snow's, Leamington, Cattell's Eelipse, and one or two others. The seed may be sown in rows or broadcast, the soil should be rich, and the position open for producing sturdy plants.

DWARF KIDNEY BEANS.—Those in pots are now bearing freely, but in this stage are apt to be infested with red spider, and are therefore better out of vinerias. Give abundance of water; liquid manure will also benefit the plants. It will be a long time until plants bear in the open air, therefore one or two more sowings should be made under glass.

PEAS.—Those raised under glass and well hardened should, when the weather is favourable, be transferred to the open ground. Disturb the roots as little as possible, the secret of success being not to check them in any way. Plant them in the most sheltered part of the garden, surround the roots with soil in which they are sure to grow freely at once, and immediately after planting stake them for shelter, but not so closely as to shade them from sun. Main crop Peas sown now will pod in July, and as the weather may be hot and dry then it is often advisable to sow in trenches.

GLOBE ARTICHOKE.—These are much valued in some gardens, and we find them extremely useful from midsummer until late in autumn. Old plants have wintered well. Some good manure should be forked round the plants. Last season our old plants were over by September, but those transplanted gave heads until December.

YOUNG VEGETABLES UNDER GLASS.—Early in April is usually a good time for transferring Cauliflowers, Lettuce, Brussels Sprouts, &c., to the open ground, but they must be duly hardened before undergoing this change. These crops will prove exceedingly useful, and they merit the most careful attention.

RADISH.—These are one of the first crops to gain maturity in the open ground, and from now onwards a small bed of seed may be sown every fortnight. Birds are particularly fond of Radish seed, and it may be necessary to net the beds until the plants are well in leaf.

CARROTS AND POTATOES IN FRAMES.—Potatoes are fast gaining maturity. When advanced they are much benefited by liberal ventilation, so long as it is not given to produce a check. It is unsafe to leave them exposed at night, as a few degrees of frost would ruin them. Early Carrots must be thinned to prevent crowding. If they are 2 inches apart small yet useful roots will form, and when some of them are drawn out then the others will have sufficient room. Do not allow them to suffer by want of water.

STIMULANTS FOR ASPARAGUS.—A sprinkling of salt, soot, or guano may be given to the surface of Asparagus beds at the present time with great advantage.

PLANT HOUSES.

Zonal Pelargoniums.—Cuttings may now be rooted for flowering during the autumn and winter. Select sturdy shoots, and insert them singly in small pots. They will root freely in any position where the temperature ranges about 60°. Do not insert small weakly cuttings. These are much better on the stock plants until they grow and gain strength. Do not let these draw up weakly in a shady place or in too much heat. They will grow sturdily in a temperature of 55° if fully exposed to light and a little air is admitted to them daily. If the old plants have been in their pots for a long time give a pinch of artificial manure on the surface of the soil. This will induce vigorous growth. Strong cuttings that have been rooted in small pots will soon flower if placed in 4½-inch pots and stood close to the glass in a temperature of 50° to 55°. They draw up weakly in too much heat, and the trusses are small in comparison to those allowed to develop gradually.

Clematis indivisa lobata.—Where this has flowered and the plant has covered the space allotted to it, the shoots that have flowered may be well pruned. Nothing is gained by allowing the plant to become crowded, but the reverse. The shoots should be trained thinly and fully exposed to the sun. A free use of the knife will induce the formation of robust growth, which should be encouraged, for on these next season's flowers will depend. This is a very effective and useful climber for the conservatory as well as the coolest structures. If the plant is infested with scale, syringe with a solution of petroleum and water at the rate of one ounce to the gallon. It is liable to the attacks of aphides, which are best destroyed by fumigating with tobacco. If the plant is confined at its roots, remove a portion of the surface soil and top-dress with equal portions of loam and decayed manure. A little artificial manure sprinkled over the surface before the top-dressing is placed on will induce the roots to come to the surface.

Greenhouse Rhododendrons.—These may be produced in succession by gentle forcing. On no account should they be hurried, or the flowers will fail to develop. The house in which they are forced may be kept moderately close and moist; no more artificial heat should be used than is necessary to maintain a night temperature of 50°. The syringe should be used freely to keep thrips in check, in fact these plants may be syringed from the time they show signs of movement. A dry base for the pots to stand upon, and dry atmospheric conditions, are detrimental to these plants. They should have a cool moist base, and should never be allowed to become dry at their roots. Any shoots that are not flowering may as soon as they burst into growth have the young shoot pinched out. This will induce them to make two or more shoots, the same as those that flower. The main stock of plants that are not wanted in flower may have cool airy treatment. For covering walls that

are exposed to the sun Rhododendrons Gibsoni and Princess Royal are invaluable.

Daphne indica.—These succeed well if given the treatment advised for greenhouse Rhododendrons, in fact they should be grown in the same structure, and with care good specimens may be produced. These, like the above, are often ruined by the atmospheric conditions to which they are exposed. If they are too hurriedly forced into flower more harm than good results. These plants cannot long endure a close confined atmosphere. Liberal syringings they enjoy as well as abundance of air. No harm is done by closing the house early in the afternoon during the season of active growth. They should be fully exposed to the sun and watered with the greatest care. They should never be allowed to become dry, and, on the other hand, if they are overwatered and the soil rendered sour failure is certain to result. Any plants that need potting should be attended to at once. Drain the pots carefully and liberally; over the drainage a layer of moss must be spread before any of the soil is placed in. Perfect drainage must be insured. The soil may consist of good fibry loam, one-seventh of decayed manure passed through a fine sieve, and coarse sand—a liberal quantity of the latter should be used, and press the soil firmly into the pots. Plants that are in good condition at their roots and are straggling through neglect may be well cut back. They will break freely, and in two years make healthy flowering plants. Shoots that fail to flower must have their points removed just previous to flowering, then the whole of the shoots start into growth at the same time.

Daphne Mezereum.—This is beautiful in pots for flowering indoors early in the season, and for this purpose should be grown in pots the whole season. When the plants are lifted annually from the outside and placed in pots for forcing a good stock of plants is necessary. When once the plants are established in pots they grow freely afterwards and flower profusely every season; all the attention then that is needed after flowering is to harden the plants carefully and plunge them outside.

THE BEE-KEEPER.

NOTES ON BEES.

THE weather is still backward for bees; they are, however, advancing, and many hives are well forward with worker brood, and drones are being brought forward in considerable numbers, but not to the injury of the hive. The mild season, together with the hives having abundance of stores, is the sole and direct cause. Unfed hives are the most advanced. The Gooseberry bushes will be in flower in a few days, and should the weather be favourable bees will be in a fit state for swarming early in the season. The majority will be allowed to swarm; after manipulations will prepare them for the Heather.

THE PUNIC BEE.

This is becoming more and more interesting as the year advances, working at times when no other bee is abroad, and so hardy do they seem that they are a marked contrast to the Syrians, which are as eager workers, but their tenderness is a defect.

FEEDING.

Although the weather may be fine this must not be overlooked. The great numbers of hatching brood demand large supplies, much larger than are generally obtained during the month of April.

ARTIFICIAL POLLEN.

The supply of this should not be neglected if the weather turns unfavourable; giving it inside the hive prevents the tear and wear on the bees, necessitated when they have to go outside for it. Have it rather thin than too thick, and see at all times that the honey the peameal is mixed with has been taken from a healthy hive. If medicated food is an advantage then Mr. Wm. Hogg's method of medicating the pea meal is far ahead of medicating the syrup, as it goes direct to the brood, which are those that take the disease.

CAUSES OF FOUL BROOD.

It is many years since foul brood appeared in any of my hives. This immunity is entirely owing to my system of thorough ventilation at all times, whether it be in the apiary or when in transit. Crowding the bees into little space at one time, and then "spreading

the brood," are two prime causes of the disease. Overheating in a humid atmosphere acts upon the pollen in such a manner as to incite the disease readily into the most virulent form, and the queen has to suffer all the inconvenience of an overheated hive. It is probable the eggs in her ovaries nearly ready for hatching may be rendered fit to start the disease through loss of stamina and a weakened constitution. Overheating doubtless brings on foul brood, and so does kept unsealed honey when supplied to bees. The beginner should, therefore, become fully impressed with these facts, avoiding both to the fullest extent by using as an antidote the means that were never known to propagate foul brood nor to harbour it.

DEATH OF A SUCCESSFUL BEE-KEEPER.

The Rev. A. McLaren, D.D., died at his residence, Houston Manse, on Sunday, 23rd March, in his 60th year, leaving a widow and three sons. Mr. McLaren was of a kind and affable disposition. He took a great interest in all that tended to the welfare of the parish and parishioners. The parish of which he has been minister for thirty years, and also Chairman to the Parochial Board, will lament his loss. As a bee-keeper few surpassed him. His successes have been given from time to time in these pages, and he was amongst the first to discover the superiority of the Ligurian bee and its crosses. He was a great advocate of the Stewarton hive, and a visit to his apiary during the honey season could not fail to convince the most sceptical of its superiority. All the work of the apiary and the garden, which were kept scrupulously neat, was performed by himself. During the last year he contributed a series of practical articles on bee-keeping to the *Evening Times*, which were received generally with much acceptance. His mode of encouraging bee-keeping amongst the working classes was to present them with bees and visit their apiaries, giving advice as required.—A LANARKSHIRE BEE-KEEPER.

ORIGIN OF MOVEABLE FRAME HIVES.

IN reply to a request for information on this subject we cite what appears relevant from "The Apiary."* From "time immemorial" there have existed bar hives; indeed, they have been traced to the ribbed carcase of Samson's lion. But in most cases the bars were not moveable—they were simply designed to aid the purpose of keeping an upper storey in some degree clear of the queens intermeddling. And even when they were capable of removal they added but a slight step in advance, and the credit of the inventions of Golding in England and Dzierzon in Germany is due, not to the bars themselves, but to their mode of affixing, and especially to the guide-comb attached beneath. At about the same date with these there appeared a Russian hive known as the Propokovitch, which consisted in an arrangement of several storeys of frames inserted endways and resting on cross pieces below them. Thus one invention supplied bars without frames, while the other offered frames without bars. But the right idea has now been caught, and it is not surprising that several apiarians, independently and simultaneously, were engaged at this period in working it out.

Briefly summarised the sequel is as follows:—In 1841 our own countryman, Major Munn, obtained a patent in France for his moveable bar-and-frame hive, of which he published a description in England in 1844; in America in 1851 Mr. Langstroth completed the invention of his moveable bar frames; and in Germany in 1853 Baron von Berlepsch by a distinct inventive process added the frames to Dzierzon's bars. Thus England appears after all to possess the honour of the contrivance, although we certainly proved the last to make of it any general or extensive use. Major Munn's original hive opened at the back, and when in 1851 he reappeared in print with a hive opening at the top he had altered the frames (and hive too) from oblong to triangular. Probably one reason of the invention's failure was the expensiveness of the Major's fittings, which are such as to make the hive appear in his engravings more like some astronomical instrument than a box for bees and honey. Be this as it may there was practically no such thing as a frame hive in use in England till 1860, when Mr. Tegetmeier was the means of reintroducing it—whether from Germany or America we are not quite sure. The German hives, however, open at the end, while Mr. Langstroth's are like our own, so that whoever was the inventor of bar-frame hives the hive of English apiarians comes nearer to this gentleman's than to that of anyone else. Mr. Woodbury it was who afterwards brought out the frame hive which met with the first general acceptance in this country.

TRADE CATALOGUES RECEIVED.

W. H. Hudson, Tottenham, London.—*Catalogue of Japanese Lilies*.
J. Cheal & Sons, Lowfield Nurseries, Crawley.—*Catalogue of Dahlias*.
Rawlings Brothers, Old Church, Romford, Essex.—*Catalogue of Dahlias*.
William Paul & Co., Bridge of Weir, N.B.—*List of Pansies and Pinks*.
L. Jacob Makoy & Cie, Liège, Belgium.—*List of New Plants*.

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Celery (Reader).—Wright's Grove White grows thrice the size of Sandringham, and consequently requires more space for affording sufficient soil for earthing. The smaller variety usually keeps much better than the other for spring use.

Cyclamens (A. H. S.).—The Cyclamen flowers do not possess any distinct character. They represent an ordinary strain, and if you visit any of the London shows or meetings in the spring you would see many plants with much larger flowers and richer colours.

Chicory (H. T. H.).—Chicory is grown practically the same as Parsnips, by sowing the seed in deeply worked fertile but not freshly manured ground towards the end of the present month or early in May. After writing you would perhaps see our reply on the subject to a correspondent on page 270 last week. If you desire any further particulars, and indicate their nature, your letter shall have our attention.

Salad Plants (H. R. W.).—If you send us a list of what you have obtained we will tell you what we know about the plants and their cultivation. We cannot give translations of names that are not before us. We are not free to publish Mr. Vilmorin's paper as read at a meeting of the Royal Horticultural Society, all papers read there being reserved for publication in the Society's Journal for distribution among the Fellows. We shall be glad to nominate you if you would like to join the Society and share in the privileges to which Fellows are entitled. Vol. xii. of the Journal is just issued. It contains the papers that were read at the Vegetable and Chrysanthemum Conferences, salad plants being enumerated in the vegetable department. The price to non-Fellows is 5s.

Disbudding Vines (M. N. O.).—Remove weak growths. When the laterals are firmly established in position and no longer liable to be broken in securing them to the wires, these laterals being about 18 inches apart, no fresh growths will be required between them, and it will be better for the Vines if there is none. Much harm is done by having too many growths from the main rods of Vines, this preventing the due expansion of the foliage, and when the leaves cannot develop under the full influence of light they cannot elaborate the crude sap supplied by the roots and store nutriment for the support of the Vines. Future growths are produced from the buds at the base of existing laterals after these are pruned in the ordinary course. It is desirable to make sure of the safety of the permanent laterals before removing all the superfluous growths.

Ferns for Cutting (W. R.).—If the majority of the fronds have been cut the plants may now be trimmed, repotted, and placed in heat. Pots 5 or 6 inches in diameter are the most suitable size, and if the roots have filled the pots the plants can be divided and again potted in the sizes named. One of the best systems of growing Adiantums and Davallias for supplying fronds for cutting is to place a good number of plants in wire baskets 8 inches in diameter. It is often difficult to find stage room for as many Ferns as are required for this purpose, but when grown in baskets they can be suspended at the back of vineries, or in any position where shade from bright sunshine and free ventilation can be given. This is the best of all plans by which a bountiful supply of fronds can be produced with a minimum of labour and trouble. Adiantum Pacotti is an admirable variety for supplying fronds for buttonhole bouquets, and

should be grown where Ferns are in demand for this purpose. The plants started some time ago should be grown without shade for the present, and as cool as possible to harden the fronds.

Shamrock (*S. T.*).—The botanical name of this is *Oxalis acetosella*, the common Wood Sorrel, or Shamrock. The plant is a native of the moist shady woods of this country, Europe, and North America, and is one of the most elegant of wild flowers. It delights in retired shady woods, groves, and hedges, and flowers in April or May. It was called by the old herbalists Alleluja and Cuckoo's Meat, because, as Gerard says, "when it springeth forth, the cuckoo singeth most; at which time also Alleluja was wont to be sung in our churches." But Alleluja is merely a corruption of the Calabrian name Juliola. The whole plant has a grateful acid taste, much more so than the common Sorrel, and is on that account used in salads and in sauces. In Lapland it is so plentiful that Linnaeus says the inhabitants of that country take scarcely any other vegetable food than Sorrel and Angelica. The expressed juice of the plant is employed to remove spots and iron moulds from linen, and this it does by the great quantity of binoxalate of potassa which it contains. Twenty pounds of the fresh leaves have been found to yield 6 lbs. of juice, from which 2 ozs. 2 drachms and 1 scruple of salt, besides 2 ozs. and 6 drachms of an impure saline mass are obtained, and is sold under the name of salt of Sorrel and essential salt of Lemons.

Uses of the Terminalias (*B. S.*).—The plant is no doubt a species of Terminalia, and the following uses have been described:—The roots of Terminalia alata are used in India as a febrifuge, and the powder, mixed with oil of sesamum, is employed. The juice of the leaves is injected into the ears to cure earache. *T. agentea*, a native of Brazil, yields a resin similar to gamboge, which is purgative in the dose of half a scruple. *T. catappa*, a native of India and the Mauritius, produces a fruit 3 inches long and egg-shaped, the kernel of which has a flavour of Almonds or Filberts, and from which a soil is expressed equal to the best olive oil that does not become rancid. They are used for tarts and for pectoral emulsions. The Indians employ the juice of the leaves, mixed with rice water, to moderate cholic, the heat of the bile, and to allay headaches arising from bad digestion. The wood is white, hard, and useful for a variety of purposes; and the tree itself, on account of its beauty and the shade it yields, is planted about houses. *T. mauritiana* is a resinous tree growing in the Isle of Bourbon, and there called False Benzoin. It furnishes a sort of resin called gum benzoin, distinct from benzoin. Its bark is thick, covered with a yellow, resinous, and fragrant dust, which colours the saliva a greenish yellow colour; it is of an astringent taste, and serves to tan the skins of the country where it grows; its decoction precipitates iron black, and it is employed in the island as a sudorific. The kernels of the fruit of *T. moluccana* are eatable, but do not yield any oil. *T. vernix* is one of the trees which furnish the celebrated Chinese black lacquer. Its juice is said to be caustic, and its exhalations dangerous.

Sunflowers for Use (*Gardener*).—Perhaps the following information will be suitable for placing before your employers. The produce of seed per acre depends on soil, situation, and culture, but has been found to average about 50 bushels—equal to 50 gallons of oil and about 1500 lbs. of oilcake; and the stems of the crop, if burnt for alkali, will yield about 10 per cent. of potash, while the leaves may be dried and pulverised and mixed with bran for fodder. The crop, however, has a very scourging effect on land, and particularly robs it of potash, and is peculiarly unsuitable for going before Potatoes in a rotation. The soil most suitable is light, friable, and richly alkaline, and does admirably well to be manured with fresh seaweed; and if loamy or clayey may be advantageously prepared by commixations of shell sand, limestone gravel, or any other opening calcareous substance; and, in any case, must be well tilled and finely pulverised. The situation most suitable is a moderately sheltered one, with sufficient exposure to enjoy free and constant circulation of the air. The sowing may be done at any time in April when the weather and soil are favourable. The rows should not be less than 2½ feet apart and the plants 18 inches asunder. Kainit is one of the cheapest and best manures for this crop, and a dressing of 5 cwt. per acre, with two of superphosphate of lime would not be too much, 1½ cwt. of nitrate of soda to be applied as a top-dressing after the plants are fairly growing, if they do not make satisfactory progress. About 2 bushels of seed will suffice for sowing an acre at the distances recommended. Especial care should be directed to remove all weeds for about a month or six weeks, and occasionally to mould up the earth around each plant. When the heads are quite or nearly ripe, the plants should be cut down at about an inch from the ground, and removed to a shed or some other place of complete shelter from rain, and there left till they become dry; and either then or afterwards they may be freed from the seed; but they must not, in any case, be left on the ground, as they have a great capacity for moisture, and would be very likely to attract it and to become filled with insects.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures,

it being often difficult to separate them when the paper is damp. (*M. T.*).—1, *Narcissus pseudo-Narcissus*. 2, *N. poeticus*. 3, *N. incomparabilis*. (*G. B. S.*).—1, *Doodia aspera*. 2, *Pteris longifolia*. 3, *Sclaginella Martensi*. (*Amateur*).—1, *Odontoglossum Edwardi*. 2, *Cyrtopodium punctatum*. 3, *Cattleya Trianae*. 4, *Oncidium concolor*. (*E. H. B.*).—Even if we undertook to name Roses, which as florists' flowers we do not, but only "species" as indicated above, the specimen you forwarded was crushed and shrivelled beyond identification. (*A. O.*).—All the flowers you have sent are florists' varieties, having originated from seed, and of these there are many so closely resembling each other that the only certain method of determining the identity of those without names is by comparison in a large collection or a specialist in charge of a collection might possibly name some from memory. As above stated, we only undertake to name species of plants when characteristic specimens reach us in good condition. (*T. W. S.*).—1, *Hippeastrum aulicum*. 2, *Adiantum hispidulum*. 3, *Chlorophytum orchidastrium*. 4, An excellent variety of *Dendrobium Wardianum*. 5, An ordinary form of *Dendrobium Wardianum*.

Bees—Old Comb (*Delta*).—The sooner you remove all the black comb, like the sample before us, and give fresh foundation, the better. Bees might possibly be raised in the old comb, but they would be small and weak.

COVENT GARDEN MARKET.—APRIL 2ND.

TRADE very dull in view of the holidays. A few samples of new Grapes to hand from 5s. to 10s. per lb. Strawberries in good supply, meeting a heavy sale.

SWEDES.

So high a place is assigned for Turnips among farm produce, that the reviser of Stephen's "Book of the Farm" tells us in the part recently published, that the Turnip crop has to a large extent given to Scottish agriculture the eminence it has attained, and it has made the eastern half of Great Britain the greatest cattle feeding district in the world. This certainly appears a somewhat bold statement, but it has the logic of facts to support it, and for example we may take Norfolk as a central county in that district where cattle-feeding and Swede-growing are pre-eminent. The cattle, we much regret saying, are not bred there, but the roots are grown there, and it is our experience of Norfolk root-culture that prompts us to write this article.

A weak point in the culture of any crop is precisely that which proves a hindrance to the ordinary and therefore the general practitioner. The weak point in Swedes is the tendency to mildew of the early sowings. Well, the fact that some of the early sown Swedes suffering from the attacks of mildew is patent enough to all who have tried them, but it has no weight in Norfolk, and the practice of sowing Mangolds early in April, and following at once with the first crop of Swedes, is a custom of that county which nothing outsiders may say will alter. Certainly from all we have seen of Swede culture in that county Norfolk farmers can teach the rest of us something, and have nothing to learn from us; yet in the adjoining county of Suffolk there is an interval of fully a month between the sowing of Mangolds and Swedes. Our especial attention was drawn to this matter from observation in Norfolk, and from the invariable superiority of the Swedes of one of our Suffolk farms in the hands of a tenant farmer. He was the younger son of a large landed proprietor; he had learnt farming in Norfolk, and instead of seeking his fortunes in the Colonies, had wisely resolved to stick to the old country and see what he could do with one of the numerous vacant farms which are now to be had at a nominal rent. He was intelligent and observant, and he found it answer much better to follow the Norfolk practice with Swedes rather than adopt that of his Suffolk neighbours.

For these reasons, combined with the results of our own practice, we again recommend our readers who have suitable soil to sow the first crop of Swedes in April, and there can be no better preparation for this useful crop than sheep folding on Rye, for we have only to follow the folds closely with the plough and to sow on the flat to be tolerably certain of a full crop. But if the land is poor then we would prepare for it very much as for Mangold; only if a full dressing of chemical manure is required use only half cwt. nitrate of soda per acre, with three-quarter cwt. muriate of potash, 2½ cwt. steamed bone flour, and 2½ cwt. mineral superphosphate, placing the farmyard manure in the furrows precisely as for Mangolds, and drilling the whole of the chemical manures with the Swede seed.

Exception has been taken to sowing Swedes on the ridge from the fanciful idea that the plant would be more liable to suffer from drought than if sown on the flat. We have repeatedly explained how admirably both ridge sown Swedes and Mangolds withstand drought when sown early on the ridge, because the roots obtain so much moisture from the dung when once the plant is growing freely, and there is the additional advantage of a fine seed bed and deep friable soil. The ridges practically vanish under the frequent use of horse and hand hoes, and in autumn it is an easy matter to decide from its appearance whether a crop was sown on the ridge or flat. The quantity of seed per acre is ruled by the condition of the soil. If it is fine, as it ought to be, 3 lbs. of seed

is sufficient, but when it is less friable from 4 to 5 lbs. of seed may be required to allow for losses through roughness of soil or fly. This early crop is less liable to suffer from attacks of fly than the later ones, but it does suffer occasionally, and we lost plant so much from fly last year on part of a field that it had to be resown. Useful as farmyard manure is to Swedes, it is not indispensable, and those farmers who are only able to procure the chemical manures we recommend may use them with full confidence, for we may remind them that under the experiments conducted in Sussex by Professor Jamieson, a crop of 29 tons. 17 cwt. of Swedes per acre was obtained in pure sand practically without organic matter, the only plant food in the soil being that of the manure mixture. This was in 1882, and the following year the Swedes in the same field weighed 30 tons 7 cwt. per acre, and Professor Jamieson said he had never seen so heavy a crop even in his own county of Aberdeenshire, famous as it is for Swede culture.

WORK ON THE HOME FARM.

That important factor to successful farming, the weather, has been more than usually fickle since our last note was written, and there has been so much rain in the eastern counties that corn sowing has been brought to a standstill. It is true enough that sun and wind soon render the surface dry enough for the resumption of work, but farmers on the Essex clays will hardly get a warm, dry, fine seed bed for the Barley which they persist in sowing. Well indeed will it be for them if they are induced by adverse weather to sow Oats instead of Barley.

In the counties west of Rugby the weather has been so favourable that western farmers are well forward with all their corn sowing. Most west country farms have a better adjustment of cropping than those in the east, and we may give as an example of this sound practice Lord Spencer's co-operative farm at Harleston of about 330 acres equally divided into permanent pasture and arable crops, of which last year about 92 acres were under corn, and 74 under roots and seeds. Of four farms of about the same size which are in hand in East Anglia, only one has 80 acres of pasture, the pasture on each of the farms being 30 acres. This preponderance of arable land was an outcome of dear corn. It continues by mere force of habit and custom, and it has made the struggle with the difficulties of hard times much more severe than it would otherwise have been.

Never have we been more strongly reminded of the urgent need for shelter for grazing animals than during the recent broken weather. We have seen horses, cattle, and ewes with lambs all turned out to take their chance upon rough stubble feed, without any dry food, and practically without shelter. Only a few hours before writing this note we saw the sheep being driven to market for sale in wretched plight. Foot-rot and hunger had rendered the ewes very low in condition, and some of the lambs were so weak that they had to be carried. Certainly he would be a bold man who would risk his means in the purchase of such animals. Upwards of forty lambs died last season in a flock of several hundred, which had been got together at auction sales, and which were sent to us for feed upon an off-hand farm. They were the property of a large flock-master who goes from market to market and buys "anything," and it is in this way that a sale is found for such starvelings.

REMARKS.

- 23rd.—Frequent heavy showers of rain and occasional hail with intervals of bright sunshine.
 24th.—Occasional gleams of sun early; frequent spots of rain from 10 A.M., and heavy rain from 4 to 7 P.M.; fair evening.
 25th.—Cloudy all day.
 26th.—Cloudy early; bright mild day.
 27th.—Cloudy throughout.
 28th.—Cloudy early; fine bright day.
 29th.—Brilliant early; cloudy by 10 A.M. and only occasional sunshine after; bright moonlight night.
 ▲ fine warm spring week, the maximum in the shade on the 28th being unusually high for March.—G. J. SYMONS.

THINNING AND DISBUDDING.

PROBABLY no operations in gardening are more important than the early thinning of seedlings, both of flowers and vegetables, and the timely disbudding of Vines and fruit trees to prevent the overcrowding of their growths. But essential as this work is there are very few gardens in which it is systematically and properly conducted. The drawing of small seedlings from a crowded mass is a tedious occupation, and the time devoted to it is often begrudged, while the duty is commonly neglected by men who cannot, as they say, "fiddle and potter about, but must be doing something to make a show." And it is not gardeners alone who are given to that line of reasoning, but there are those above them who are not over-satisfied to see strong men engaged in such light-fingered movements, but prefer to see them more laboriously employed. It is impossible to say how many crops have been weakened and how many millions of plants spoiled through the crushing and crowding to which they have been subjected in the early stages of growth, and the lightest work for affording them space for development is often the most profitable that can be engaged in. A gardener who knows his business is fully alive to the importance of such apparently small matters, and if he is allowed to do what he knows wants doing the first, or has not two or three men's work before him, he will not permit either plants, Vines, or trees to suffer by want of timely thinning or disbudding.

It is impossible to attach too great importance to the operations in question. An example of the value of adequate space to plants from their first appearance above ground may be adduced from a very simple crop—Radishes. Sow the seed thickly, and allow the plants to remain to struggle with each other in a densely crowded mass; the crop will be worthless, and seed, labour, and ground wasted. No great loss, perhaps someone may be inclined to suggest—"only a few Radishes." There are men, no doubt, who make light of small failures, but they are rarely notable for great achievements. But we have not done with the Radishes. There are at this moment scores of acres growing in the London market gardens, on land occupied at a rental of £8 to £10 an acre. Obviously it must be rich, and the crops well managed, or it could not yield a profit to the tillers. Suppose a man has five acres of Radishes spoiled by thick sowing and dense crowding, would the loss of such a simple crop be trivial? On the contrary, the wasted seed, fertility, and space would be serious. Bad management of that kind means ruin, but it is not allowed by good cultivators; and five acres of Radishes, thinly sown, thinly grown, early and clean, bring a return of from £20 to £40 an acre. This, if anything can, will enforce the lesson that we desire to impress on all who need it of the importance in the first place of thin sowing, then if the plants come up too thickly of the necessity of thinning them quickly and sufficiently. For preventing needless expenditure in two ways—waste of seed by its too lavish use, and the consequent cost of thinning the plants—one of the largest and most successful of market gardeners sows his own seed with his own hands, though his weekly wage bill exceeds that of a thousand acre farmer.

The principle advocated applies to all plants and crops that are intended to develop into objects of beauty or usefulness, from Lobelias and all other flowers raised in pots under glass, also

Celery and whatever vegetables may be raised similarly, and equally to open ground crops of Turnips, Carrots, Cabbages, or whatever may be raised, including flowers. Let them remain crowded too long and grow too tall, and nothing that can be done afterwards, including thinning, can atone for previous mistakes or neglect. For insuring strong plants of the most satisfactory kind the seed leaves or cotyledons should never touch each other. That is the first condition for robustness of habit, and the subsequent withdrawal of superfluous plants should never be deferred till those which remain fall over, because not strong enough to stand alone. It is impossible that such weaklings can be satisfactory and a credit to the cultivator; moreover, this late thinning of root crops, such as Onions and Carrots, simply invites the attacks of their natural enemies—maggots—by the easy vulnerability of the tender stems and the accessibility of the underground portions to parent insects for depositing eggs. From whatever point of view regarded, the close and long-continued crowding of young plants of all kinds cannot be too strongly condemned. It is obstructing, not assisting, Nature, and a burlesque on intelligent cultivation.

Passing to disbudding or removing superfluous growths from Vines and fruit trees. This work is not by any means so thoughtfully conducted in all gardens as it should be. In some it is deferred too long; then, as if to make up for past omissions, the removal of the crowded growths is excessive. It is a mistake ever to allow any crowding of the foliage, yet it is not too much to say that this error is apparent every summer in more than half the vineries and Peach houses in the kingdom. One good leaf that develops under the direct action of light is of more benefit to Vine or tree than ten crushed, crowded, and shaded, hence flimsy examples. These are tree weakeners, abstracting more than they return, for they cannot elaborate the crude sap and secrete nutrient matter for the wood and fruit; but leaves of the best character, fully textured and their functional powers developed, are tree strengtheners, for they return more nutriment than they abstract for their own support. The more of these perfect leaves there are the better, therefore undue suppression of growths should not be practised, but by far the commoner evil is an unreasonable multiplication of parts each struggling with the other for sun and space, and all suffering by the effort.

The first and most effectual measure for obviating the evil in question is the removal of those growths when quite small that are obviously not wanted for occupying space, for the sufficient reason that there is no adequate space for them to occupy. A little forecast of the space that starting growths will need for the full expansion of the foliage will enable a decision to be arrived at relative to the removal or retention of those growths. Yet prudence must be exercised and allowance made for accidents, especially in the case of Vines, or a blank may be created that cannot be easily filled. The growths actually required for permanent positions must be absolutely safe before all others near, some of which might be useful as substitutes, are taken away.

Newly planted Vines need particular attention. The canes of many are much too long for stout growths to be produced. The sap is divided into too many channels to flow in full force, and a concentration on fewer outlets will increase the momentum, and consequently the strength of the growth extensions to which it is directed. Therefore it is often highly desirable to gradually remove a number of shoots from the upper parts of canes that were not sufficiently shortened before planting, and at the same time the lower parts of canes from which fruit-bearing laterals are not required should not be wholly denuded of buds as many are, but it is better to let a few leaves expand for enlarging the sap vessels and strengthening the stems. Established Vines, except in the charge of the best Grape growers, are usually permitted to become much too crowded, and this alone is the cause of many failures or inferior fruit. The too free extension of laterals can and should

be prevented by timely, yet gradual, and judicious disbudding and removing superfluous growths.

Fruit trees both indoors and out also need thoughtful attention, with the object of producing healthy fruitful wood, and this cannot be insured if the growths are not thinly disposed. The remarks of Mr. H. Dunkin on this subject in another column are worthy of the attention of persons, and they are numerous, who have not had the same good training in the management of fruit trees that enables him to give such sensible advice.

AN AMATEUR'S EXPERIENCE WITH ORCHIDS.

[Read by the Rev. F. D. Horner at a meeting of the Wakefield Paxton Society.]

It has been said that the way to learn a subject is to write a book about it. I do not say that the way to grow Orchids is to lecture upon them, but I could not venture to lecture upon them if I had not grown them. As mastery of the subject must precede the writing of the book if it is to be worth anything; so in a lecture on our experiences, it needs must be that we should first have had experiences to speak of. In Orchid culture mine do not extend beyond a modest range, but through the eight years in which I have been able to watch and tend them very closely, I can see, far past all I know, how vast is the great dark land of that which I know not. This leads me to express the hope that you will suffer me to turn the lecturer's table upon you in this way, that, while very glad to answer any questions I can, I may be allowed to ask questions in return, of Orchid growers more experienced than myself.

I have some Orchids that baffle me. I daresay we all have. There is the Orchid of wide repute as a miffy grower with anybody, and yet we could not resist having an attempt at it ourselves. There is the Orchid, now doing well, that has refused a dozen offers of other situations in the very same house. Again, the Orchid that went on amazingly for a while, but now, under no change of treatment whatever, is growing "small by degrees and beautifully less." There are Orchids that have always grown most generously with me, such as *Cattleya citrina* and *Dendrobium Falconeri*, and yet they are not happy in some collections, and there are some which I cannot keep up for long that someone else can manage very well.

If there is time, I would gladly ask about these after your questions have been put. Were we all strangers one to another such a course might seem out of order, but as being alike entitled to write "M.P." after our names, as "Member of the Paxton," I feel as if no such barrier need intervene.

Of course we know, and the reflection is one which Orchids seem specially constituted to call up, that not one of them can feel quite at home with us. All have somewhat to bear with, on points of importance—seasons of shorter daylight than they ever have at home, and days of greater length than they ever knew before, perhaps seasons changed and protracted for rest and growth, and subtle differences in air and light. We can give them neither the intensity of their native sunshine, for under glass ours is not the same, nor the richness of their native shade, nor yet the luxurious downpour of their own rainy seasons. Captives in a strange land, some will always feel this keenly. Thus will such become our miffy growers, our unwilling guests, that little by little sidle towards the door, and silently steal away.

In the culture of Orchids, and indeed of all my favourite florist flowers and other plants, I am an "amateur" in the simplest meaning of that word, which signifies "a lover," and also in the sense of being my own head gardener and foreman, and my own "man under him." However, I have as helpers, and in part as pupils, a "man-and-boy"—a combination not infrequently to be met with in rural homes of "the undignified clergy!" What I ought to apologise for calling "the range" of Orchid houses has grown from time to time as the plants increased, and somehow the plants have increased as the houses grew; still, the length of them altogether is only 87 feet. All the warm and intermediate house Orchids grow in a twice-lengthened lean-to, about 40 feet long and 10 feet wide, and 10 feet high at the back. This range runs east and west, and has a full and clear south aspect. The houses for cooler and cool Orchids are two span-roofs, each 20 feet by 12 feet, and 8 feet high in the middle. They run north and south, and catch the morning and afternoon sun, but are sheltered at mid-day by tall Yews, not near enough, however, to overshadow them. I like several smaller houses better than one large one for Orchids, and as these contain among them 430 varieties and 911 plants you will see that the plants cannot be very large specimens, nor live very far apart. As with the houses so with the plants; I would

rather have them of moderate size and fair blooming strength than in "magnificent masses." Plants of a medium size are more readily looked over, and signs of mischief cannot be too easily detected. They are in fairer proportion to houses such as mine. I can grow more varieties, and can place the plants close enough together to need no adventitious foliage, as of Ferns, to fill up blank spaces. Mine have several times been in danger of getting too close, but it has been for want of more room, and not that I would conceal the natural habit of an Orchid, as though there were some ugliness to be hidden, in those that bloom from naked stems, or have grotesque or bulky pseudo-bulbs.

It is a conventional idea that all flowers must be accompanied by leaves. How many by nature are not, and when are flowers so effective and emphatic, so modest or so curious, as when seen as Nature has disposed them on the plant? No foliage suits them like their own, and those ordained to bloom without it have no need of it, either for their use or beauty. All the houses are of very simple construction. I have never aspired to build any elaborate Orchid houses. They are plain and village made, but they suit the plants well, and that is the main thing. The original house is one which I diverted from the former use of plants more or less tropical, that had indeed their day and mission, but were not Orchids, for which I may say I have always felt affection since a boy. In this old house I grew Tea, Coffee, Sugar, and Tobacco, Rice, Ginger, Pepper, and Chocolate, Cotton, Camphor, Egg Plants, Bottle Gourds (*Lagenaria*), and the long streaked snakes of *Trichosanthes colubrina*. The Sensitive Plant here was a perennial, and ripened its seeds, each curiously hung in the fringed pod like a picture in a frame. I had also a Mahogany sapling, and a few other foreign but familiar woods.

These things were of interest to many of my country parishioners, who were amused to see groceries alive, though some were disappointed that Tea and Coffee plants did not smell of what they were, as garden pot herbs do, or the too familiar Onion, while the "eggs" of the Egg Plant had neither shell nor yolk. But many of these plants outgrew the space I had for them; and when I transferred the old house from a cramped position at Kirkby Malzeard to my garden amid the sunny pasture lands and meadows round Lowfields, the tropical flora of that earlier epoch passed gradually away, and the age of Orchids dawned and grew.

Respecting the construction of the Orchid houses, I particularly wish to mention two most simple, unaffected, and effective aids towards supplying those necessities of Orchid life—a maintenance of atmospheric moisture, and an active circulation of the air when it would not be safe to admit any from outside. I am not here propounding any catchy conundrum, or vaunting any empirical patent of my own. If the one scheme is not new to you, all I would do is to add my hearty testimony to the value of it; and if the other is not new either, it virtually is so to me, for I only found it out by accident.

I will speak of that first which concerns the circulation of the air. Before the span-roofs were available I needed a small cooler compartment, which I built against part of the lean-to front, and connected this annexe for its supply of heat by removing the glass front partition between the lean-to and it; leaving, however, the brickwork below the front sashes. A stream of warm air flowed in, and under it a cold return current from the annexe set in too, and as it had to pass over a stage of warm house plants I felt that I had perpetrated a blunder. In addition to this form of failure there was another. A cold and motionless body of air, some 3 or 4 feet deep, lay in the annexe at the level of the return current, and down to the floor. The back cool current hardly ruffled the surface of this heavy, cold, dead sea of air. A lighted candle was a beautifully delicate test of this, but so indeed was I in feeling like a warm blooded animal above the waist, and a cold blooded one below; much as we might suppose a mermaid would have to be in her fishy and fleshy combination.

It then occurred to me to knock out every other brick in the lowest three courses of the partition wall. This device of course drained the dead sea, and set the whole body of air in circulation; nothing but warm air passed over the plants, and all the cool from the annexe flowed back through the brickwork channels near the floor, to be re-heated in the lean-to. In a short time there was not any chilly air in the whole circulation, and never has been since. The colder and more unsafe for admittance the outer air may be, the more rapidly does this new circulation move. The effect has been very happy upon both the growth and the foliage of the plants, and the tenderest flowers do not suffer from spot and damp in the most sullen and obnoxious weather. I have the span-roofed houses so arranged that I can have a similar action at work between them. One is less supplied with pipes than the other, both because I require it cooler, and because if the heat were equal, there might be the calm of an equilibrium, so far as this kind of circulation is

concerned, leaving each with only the usual movement of its own warmer and cooler air.

I cannot admit outside air close to my pipes, and am inclined to doubt whether all the air admitted so does really get warmed at all in passing them. Air is a bad conductor, and only the thin stream in impact for a moment with the pipes may carry much warmth with it. A quantity may pass in without being influenced at all, just as it has been found that the centre of a stream of people in a departing congregation were too imperfectly affected by a collection at the doors, the boxes having small effect beyond the thin current of humanity impinging on them. Hence the old plan, that admitted of so much passing on untouched, has given place to the happier method that reaches all! However, you will see that it is not fresh air from outside that is in question, but an active circulation of the air within. You will not take it that I suggest any substitute for fresh air whenever safe, for I give the Orchids all I can. Fresh air is always entering by laps of the glass and other narrow avenues, as may be seen by the way in which fine particles of dust get in on dusty, windy days.

My other valued auxiliary for maintaining a kindly and unfailing moistness of the air simply consists in having natural earth floors to all the houses. The pathways are made with stones and clinkers, and faced with sifted coke. There is never any drying up, and never any damping down. Enough moisture escapes from the stages to keep the earth floors always damp. Such a floor is always sweet, and need never be unsightly if it is kept lightly ruffled with a rake. It is liable to no extremes of condition, and I think it is more sweet and healthy for the plants than any hard, perhaps even ornamental flooring of the house that seems to grow nothing well because it has cost too much.

The greater part of my Orchids I have grown on from newly imported plants, and many were half established but unflowered. Some I bought in bloom, especially while at certain times we were in lack of a succession of species in flower. Now, however, there are no flowerless intervals in all the year among the Orchids; but even if there were, there is abundant interest in watching what these curious plants are doing in their wonderful habits of life and growth. It may readily be imagined that there is a powerful charm—a serene sense of security to the tremulous beginner—in reposing his early trust upon “established Orchids.” It is beginning where someone else has left off, and he will stand upon an assured foundation from the first! The period of convalescence is safely passed. He has had no anxious watching by the sick bedside; no sad burden of his dead to carry forth. Perhaps flowering strength is again attained. In all probability there is no danger now from the undetected eggs, or the ever execrable larvæ of unclean horrors in tropical insect life; and yet, as the boy said who strove to express himself in language beyond his strength, he may find he has “planted his foot on *vice versâ*.” For if the established Orchid has already been flowered in this country, there is another and a sadder light in which it may be viewed. Coming with a character as a high type in a variable species, it would of course come with a correspondingly high price, which, however, might or might not be of consequence; but in absence of these modest assurances of worth, it may be nothing but “a cull”—a cast-out from some collection more rich without it. For the amateur orchidist soon grows to be so far humanised in this as in other pursuits, as to freely set price upon and part with that which he has discerned to be inferior, and in so doing to wish he had invested in fewer Orchids, where variation in type makes so much difference in worth and beauty. I would distrust, for any high quality, the plant that has been silently proved, and comes, unwept for and unsung, to the auction room “without reserve.” The advantage of the newly imported or half-established plant is that you may have happened to select a fine type of the flower, while from among plants in a more advanced condition the probability may be gone.

ORCHIDS FROM SEED.

I very soon had yearnings to possess seedling Orchids of my own raising, and if only this branch of Orchid culture could be brought more within the range of practical horticulture, what beauties past imagining would be revealed, and how, from what we have seen of hybrid Orchids, we long for more! Of the two important points, getting the seed and getting it to grow, the first is easy compared with the second. I have a few hybrid seedlings of my own, but I suppose they hardly represent one in many thousands of seed sown. They appeared in an inverse ratio to the pains I took to sow them. After dusting them over several likely and careful contrivances for raising them, the only seeds that grew were some that I had carelessly blown about upon any basket or block or pot that would save wasting the remainder of a pod of seed. No seedling from a fine pod of *Cattleya citrina* × *C. Mossiæ*, which I sowed among the parent plants, has appeared within a year, and I do not know whether it is hopeless. Seen through a

microscope the seed seemed well developed, and so did that of *Phalenopsis Schilleriana* × *P. amabilis*, but it did not grow. I have never removed the pollen masses from the flower of any seed parent, thinking that, while secure in the capsule, there will be less danger of its own pollen accidentally touching the stigmatic surface.

There is a curious impression that whatever a flower of *Zygopetalum Mackayi* is crossed with, the seed will produce simply *Zygopetalum Mackayi*! I have some seedlings of which this *Zygopetalum* is the seed parent, and the male parents were *Epidendrum ciliare* and *Oncidium unguiculatum*. The seedlings are growing finely, and I must say they have at present a likeness to their mother. Yet I cannot think the seed parent received any influence from its own pollen, as I did not displace it in fertilising the pods, nor were any of the capsules of any of the flowers on this spike disturbed, neither was there any other plant of the kind in bloom on which the pollen might have been set free. Having the opportunity I fertilised *Odontoglossum Rossi majus* with *Zygopetalum Mackayi* (!), and there is a huge pod. Supposing this seed should grow, it will be interesting to see if the *Zygopetalum* influence can really turn this seed into *Zygopetalum* when it has had no maternal share in producing it. If that is so, there must be more strange things in Orchids than were ever dreamed of in my poor philosophy.

I have other Orchid pods of interest, but it remains to be seen whether anything will grow out of them. Among the best are two fine ones on *Vanda Sanderiana* × *Vanda cœrulea*, of which I should greatly like to see the seedlings, but have had no experience with *Vanda* seed. Others are *Oncidium Papilio majus* × *O. Lanceanum*, and *Cattleya Trianae* × *Brassavola glauca*, a large night-scented flower, of a beautiful moonlight shade of white, and a spearlike dash of crimson on base of lip. I have not been able yet to use my plant of *Brassavola* (*Lælia*) *Digbyana* as a parent. Seed-bearing is often a very perceptible strain upon the plant, or that lead of it which bears it. A *Phalenopsis* carrying a large pod never made a new leaf for two years afterwards, though it lost none. The seed-bearing lead on *Cattleya citrina* did not break the year after, though it grew again the season after that; but on *Vanda Sanderiana* the pods have had no visible effect on the subsequent growth of the plants.

The earliest symptom of fertilisation is the swelling of the column, and it is not until the turgescence of the rostellum at the head of it that the capsule confining the pollen masses is displaced, too late for them to interfere. In many cases the flower dies soon afterwards, but in *Phalenopsis Luddemanniana* the flower was persistent, thickening in all its parts, changing to a reddish green, and living till the pod was ripe. *Zygopetalum Mackayi* lost its lip, but the sepals and petals, much thickened, remained upon the pod. *Oncidium Papilio* and *Vanda Sanderiana* have retained the flower distinctly, but in a dry brown state.

(To be continued.)

NOTES ON FRUIT TREES—APPLES.

(Continued from page 276.)

My second point is that our inability (and it is a demonstrated fact) to compete with American Apples in the markets is the result of indiscriminately planting trees in locations unsuited to their producing fruit of the essential size, colour, quality, and crop to satisfy the buyer, and return a fair per-centage of profit to the grower. The orchards of Nova Scotia, Maine, Massachusetts, Connecticut, New York, and other of the north-eastern States of America are, as results of a survey of the map, more favourably located than those of the British islands. The great Apple producing districts of America lie between 41° and 46° north latitude, those of England and Wales are situated between 50° and 54° north latitude. London in latitude 51° 32' N. has a mean annual temperature of 50·1°, mean summer temperature 63·8°, and mean winter temperature of 37·3°, with an annual rainfall of 24 inches. New York 10° further south, or in latitude 41° 6' N., has a mean annual temperature of 51·7°, mean summer temperature 72·3°, and mean winter temperature of 31·4°, the annual rainfall being 36 inches. England, by virtue of the Gulf Stream or ocean current as shown by the “temperature chart,” is singularly favoured whereby it is placed in the southern part of the north temperate zone, whilst the Apple producing districts of America are placed in the northern. The British Isles lie in the southern with an annual isotherm of 68° on its southern limit, and 37° isotherm of the coldest months on the northern, whilst the limit of the other or north part of the temperate zone has an annual isotherm of 32°. The southern part of the temperate zone in which England is located has a mean annual temperature of 52½°, whilst the northern part of the tem-

perate zone in which the Apple producing districts of America are situated has a mean annual temperature of 50°. This mean annual temperature, so favourable to Britain, is highly misleading, as it is not the mean annual but the summer temperature that influences vegetation in the growth and perfection of crops, and it is in this respect that the American climate is so favourable to fruit trees. The severity of the American winter insures complete rest, which contributes in no small degree to the vital force and energy of the trees. Immunity from damage or destruction of the flowers and embryonic fruit is assured by the late spring (without frost) quickly passing into summer, and the close of the season or autumn is alike favourable to the perfecting of the crops and the maturing of the wood and buds as to the gathering and storing of the fruit. The winter also favours the keeping of American Apples, for, though the cold be 5-9° lower than the mean winter temperature of London, it is continuous and dry, not subject to the frequent changes which characterise our climate.

Against those advantages of climate we have as a set-off to place our almost absolute immunity from drought and of escape from insect ravages, which so militate against American growers that it is difficult to make choice of which have least difficulties to contend against. The American would no doubt appreciate some of the English moisture, so as to secure more juice in the fruit, and we should value an insurance of bright late summer and autumn weather, with immunity from damage or destruction of crop by late spring or early summer frosts, and other uncertainties of climate which beset orchardists in insular locations. Everything, however, does not depend upon climate. Knowledge and experience must result in ascertaining the location and capability of production, for though Nature may limit the subject's adaptability to soil and climate, much can be effected by cultivation, acclimatisation, and selection, considerably modifying Nature's inherence, and England, from the diversity of its surface, presents advantages to the fruit cultivator which, as proved by the excellence of product attending skilled and intelligent culture, is alike the envy and admiration of all mankind. Indeed it rests upon the barest supposition that the progenitors of the race of Apples now grown were introduced at various times from the Continent, and were not obtained here as direct improvements on the Crab. It is known, however, that even the Crab in its wild state evolves by "natural selection" into Crab Apples, and that though the Crab is indigenous to Britain and all the temperate and warmer parts of Europe, it is quite as reasonable to suppose that our progenitors were as much awake to their own interests as their continental contemporaries. What indeed is the Lady Apple or Api but a highly coloured and perfumed Crab, which according to the footnote to Dr. Hogg's description of this Apple, "was first discovered as a wildling in the Forest of Api, in Brittany," and that "it has been asserted that this Apple was brought from Peloponnesus to Rome by Appius Claudius." Our Golden Pippin and Old or Winter Pearmain are not claimed by our continental friends, and though claims may be laid to Ribston Pippin, it is certain that our present race of Apples are resultant of British effort on this or American soil, and that whatever may be due to introductions, much more results from improved cultural effort at home, alike on this as on the other side of the Atlantic.

Although Britain is the home of the Apple it is quite clear its surface is not equally suitable for the production of the choicest and finest fruit. Our specimens as placed on the exhibition table, and the choicest of our productions placed in the markets, are exceptionally favoured by location (some of it grown under glass), soil, and skilled culture. They, in fact, afford no criterion of the general produce of gardens and orchards. Everybody knows that they are brought together to show what can be effected by high-class culture, but they are not representative of the varieties grown under conditions that must in the main obtain when grown for profit. Of the exhibitors at the Apple Congress in 1883 how many were growers supplying the market? Nine-tenths were either nurserymen or gentlemen's gardeners! Where were the growers that place the majority of British Apples in the markets to compete with importations? Truly, they were unrepresented directly, though they were to a certain extent indirectly, as some of the exhibitors, much to their credit, pronounced some of the dishes to be selections from orchards in their respective localities. Surely if fruit such as that brought together at the Apple Congress and periodically at shows, can be grown by nurserymen and gentlemen's gardeners in nursery quarters, and in gardens or adjoining orchards, equally fine can be grown by those having the requisite knowledge, intelligence, and capital throughout the length and breadth of the land. That is the question. Dividing hedges of evergreen or deciduous subjects may be of little use in breaking the force of gales to an orchard of standards, but they are singularly effective in sheltering a plantation of cordon, espalier, bush, or pyramid fruit trees. Even should no distinct screen or shelter be provided, the trees are grown in such quantities and at such dis-

tance as practically to protect themselves from cold biting winds in spring and mitigate the severity of gales in autumn. Still, trees reared in warm sheltered nooks would not avail the grower for sale; therefore, they are grown in open if not in exposed situations, with no more shelter than they afford themselves, and as such are representative of the suitability of the dwarfing culture for general adoption.

Private gardens afford no characteristic in the exhibits of the fitness of varieties for profitable cultivation. Cordon, espalier, bush, and pyramid fruit trees have advantage of site, shelter from wall, fence, &c., which are not available generally for fruit growing for profit. In not a few instances the fruit exhibited is taken from trees that are favoured by heat radiated from walls or some singularly warm, sheltering, or heat-retaining agency, veritable sun traps, and in not a few instances the fruits are taken from trees against walls, fences, or grown under glass. In what way fruits so grown afford a criterion of adaptability for general cultivation it is difficult to understand.

Nor is the fruit produced by orchard trees as they are seen in gentlemen's places any safer guide to the would-be planter for profit, for such orchards mostly are favoured by site, have special sheltering belts of trees on exposed and cold quarters, with the additional advantage of a richly wooded park and country associated with those establishments. Statesmen, statisticians, economists of all grades beholding imported Apples flooding and commanding the markets, and comparing them with those at their and the exhibition table arrive at the conclusion that if such fruits as they use and see often can be produced by gardeners, they, or similar can be grown by the cottager and farmer. The money expended in imported Apples would, were it, or some of it, to find its way to the hardly beset agriculturists materially befriended them. The artisan with a bit o' garden scarcely big enough to "swing a cat round" plants a tree in defiance of the wind whistling round his house or the dividing wall corner, the suburbanist plants cordon and bush trees in the wrong place. Those plant for pleasure. One fruit of their own growing is valued more than a dozen from the market.

It is different in the country. There the cottager and farmer plants with a view to an abundant supply of fruit for household purposes and to sell in the adjacent towns. What do we find? The cottager's garden cumbered with trees, the fruit small, useful at home, but not looked at in the markets. The farmer's orchard is a forest of mossy stems, lichen-smothered branches, and thickets of twigs—as many dead as living. To complete the picture there are a few pollards, canker having eaten their heads off, the fence a thickset hedge of Thorn, Briar, Bramble, Sloe, and Plum-wildings, Crab, with a strong contingent of Nettles, struggling for the mastery. Yet those trees bear fruits, small and sour, which do not pay for gathering.—G. ABBEY.

(To be continued.)

FLOWER NOTES FROM KIRKCUDBRIGHTSHIRE.

THE Crocuses are nearly over, and their brilliant masses of colour are sorely missed in the garden. But the Daffodils are now to the fore, and with a moderately sized collection we hope to have some in flower until well into June. Among the many species and varieties now in flower it is difficult to select a few for mention. We find *N. scoticus*, the Scotch Garland Lily, one of the earliest here. It was only a day or two later than *N. minor*, and opened simultaneously with *N. pallidus præcox* var. *Asturicus*, and has preceded established plants of *N. obvallaris* by a considerable time. The gorgeous *Telamonius plenus* flowered within a day or two of *scoticus*, and is, despite its being so common, one of our indispensable plants. *N. Capax plenus*, Queen Anne's double Daffodil, has come well this year, but derives much of its attraction from the curious formation of its flowers, which, as Parkinson so well said, are "of a pale lemon colour, consisting of six rows of leaves, every row growing smaller than the others unto the middle, and so set and placed that every leaf of the flower doth stand directly almost in all, one upon or before another into the middle, where the leaves are smallest, the outermost being the greatest."

The beautiful little white trumpet Daffodil, which is said to be *N. moschatus* of Haworth (not *moschatus* of the Dutch, which is *albicans*), is also fully in flower, having opened on March 30th. It is undoubtedly a gem in the garden, the purest white of all, and one which should be largely grown on all light soil. Our only regret is that we have not more plants, but fortunately it is now comparatively low in price. Several of the other trumpet Daffodils are in flower, but *N. Burbidgei* and some of the *Barri* group will not be in flower for a day or two. Anemones have been

among the most useful of our garden flowers this winter. All through the winter we have been cutting flowers, and many are now in bloom. Some of the St. Brigid Anemones are very fine at present. In light soil I find it better not to lift the single varieties, but to let them remain in the ground. *A. hortensis rubra* fl.-pl. is very pleasing, being quite distinct in colour from *A. fulgens* fl.-pl. *A. appenina* is just opening its beautiful flowers. So many flowers are now opening to the genial influences of spring that it is impossible in limited space to speak of them. Arabises, Aubrietias, Primroses, Polyanthus, Myosotis, Doronicums, hardy Primulas, *Erica carnea*, and others, all in full flower, also urge their claims, but in vain, as we must be inexorable, and plead the exigencies of space.—S. ARNOTT, *Rosedene, Dumfries*.

DISBUDDING PEACH TREES.

In the formation of even, well-balanced trees, covered with fruitful wood from top to bottom, disbudding and judicious stopping play more important parts than are generally assigned to them. In more than one instance have I heard the wisdom of the extension system of pruning and training Peach trees not only questioned, but strongly condemned, but I am prepared to maintain that in nearly every instance where this system results in the production of trees with stems bare at the base, although perfectly healthy in other respects, the real cause of the evil lies in the improper manipulation of the young shoots at disbudding time and throughout the growing season. It is when the flow of sap is in full play an easy matter, by the aid of judicious pinching, to divert some of the vigour of the trees from the strongest shoots, when the sap is concentrated into the weaker, and by constant attention during the summer months the work of shortening back at the winter pruning is reduced to a minimum. By following the treatment above indicated the energies of the trees are fully utilised, instead of being wasted by growing strong shoots, to be subsequently cut away.

These remarks are intended to apply more particularly to trees under glass, as unfortunately severe and unexpected frosts just as the buds are beginning to swell, and before protection is given, will sometimes kill numbers of both wood and fruit buds (on outdoor trees), and by so doing leave many an otherwise fine tree bare at the base, as it is generally the bottom shoots that suffer the most. In disbudding Peach trees the strongest parts should have the first attention; this is generally the upper portion, although it is by no means uncommon, for very strong shoots to be found near the base. Whenever such shoots are situated about half of the young shoots should be removed, taking care to reserve one at the base, and another at the point. The moderately strong shoots should next be looked over, and a smaller proportion of them removed, while the weak ones should not be interfered with at the first disbudding, the object for this being to draw the sap (which has received a slight check by the removal of shoots from the strongest branches) with greater force to the weaker. This first stage of disbudding should be performed when the shoots are an inch long; a fortnight after the trees should be examined again. This time the thinning may be done pretty freely on those shoots that have been already operated upon, leaving the best placed, but more of them than will ultimately be required. Always give the preference to those which spring from the upper side of the shoot, although to fill up vacancies it is sometimes necessary to reserve a few from the under side. If the weak shoots have by this time made fair progress they can be slightly thinned.

At the final disbudding a careful selection of the best placed moderately strong shoots should be made. In the case of trees that have filled the extent of trellis allotted to them the matter is simple. One shoot should be left at the top of each fruit-bearing shoot, and when long enough stopped at five or six leaves. Another should be left at the base to be trained in for next season's fruiting. In the case of long shoots, young growths may be trained in at intervals of about a foot, if it can be seen that there is room for their development without unduly crowding other portions. If not wanted a few should be stopped at a couple of leaves in preference to being removed altogether. These will form close spurs, and often prove extremely useful in preventing gaps where young shoots die, as they sometimes will do. In fact it is a capital plan to stop a few young shoots at intervals all over the tree to form spurs, not on account of the fruit they will produce if left, but for the purpose of having a reserve to fill up vacancies. When young trees have plenty of room for extension it must be borne in mind that the further they advance from the main stem the greater number of side branches will be required to fill the space, leaving the young shoots at from 4 to 6 inches apart. This must, therefore,

be provided for by leaving the requisite number at disbudding time.

Throughout the growing season a sharp look out should be kept upon strong shoots that show a tendency to rob their neighbours. These should be frequently stopped and a lateral taken from the point, and in cases where there is room the side laterals also trained in. This is one of the best of all methods for bringing gross shoots into a fruitful state, as by so doing the sap is diverted into several channels, the result being numbers of medium-sized shoots in the place of a few strong ones, and by following the advice above given this result is obtained without the loss of a season's growth, which is the case when the strong shoots are allowed to ramble at will for a time, only to be cut away at the winter pruning.—H. DUNKIN.

DEUTZIA CANDIDISSIMA FLORE-PLENO.

THIS cannot be claimed as a new plant, and it was perhaps a cause of surprise to some that the Floral Committee of the R.H.S. recently

FIG. 37.—DEUTZIA CANDIDISSIMA FLORE-PLENO.

awarded a first-class certificate for a specimen exhibited at the Drill Hall; still there can be no valid reason why certificates should be confined to novelties, as some of the old neglected or forgotten garden plants are well worthy of being again brought into notice by such means. The shrub in question is valuable for its floriferous habit, the pure white double flowers being produced in long dense racemes, and have a charming appearance either cut or on the plant. It is well suited for culture in pots, and can be had in flower early by moderate forcing. About Easter white flowers of all kinds are much appreciated,

and those of the *Deutzia* would be a useful addition where it has not already been grown.

ROSE SHOW FIXTURES 1890.

- June 24th.—Drill Hall, Westminster (N.R.S.).
 „ 27th.—Royal Aquarium.
 „ 28th.—Eltham, Reigate.
 July 1st.—Canterbury, Hereford, Sutton.
 „ 2nd.—Croydon, Dursley, Hitchin.
 „ 3rd.—Bath, Farningham, Norwich.
 „ 5th.—Crystal Palace (N.R.S.).
 „ 8th.—Gloucester, Ipswich, Winchester.
 „ 9th.—Diss, Ealing, Tunbridge Wells.
 „ 10th.—Birkenhead, Worksop.
 „ 17th.—Birmingham (N.R.S.), Helensburgh.
 „ 22nd.—Tibshelf.

The only Rose Show on the above list which extends over more than one day is that at Winchester, which will be held on the 8th and 9th of July.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY (Continued from page 266.)

Perle des Jardins (Levet, 1874).—Of good strong stiff growth with fine foliage, not liable to mildew, but easily injured by rain. It does well as a dwarf, but is a Rose of shocking bad manners. We want much a well shaped Tea of a good decided yellow to take the place of *Maréchal Niel* when it is off bloom; and *Perle des Jardins* is always promising to do this, and very very seldom doing it. It comes divided or quartered or malformed in some way, almost to a certainty, during the summer, but manages to stave off execution of just judgment by the aid of better shaped and far more valuable blooms in the autumn. At that season it will often prove the only available sort which is really yellow, and even one bloom of this tint will make a wonderful improvement in a bouquet of autumn Roses. It is a good autumnal, and is quite worth growing for this purpose alone.

President (A. Paul & Son, 1860).—See Adam.

Princess Beatrice (Bennett, 1887).—I have considerable hopes of this Rose in a fine dry season as an early Tea, but have not had any good fortune with it yet. There is an H.P. Rose (W. Paul, 1872) of this name.

Princess of Wales (Bennett, 1882).—Of quite small dwarf growth and foliage, not liable to mildew, but requiring fine weather. This Rose, though unlike it in bloom and wood, is somewhat similar to *Comtesse de Nadaillac* in manners and customs. A small stem will sometimes swell and grow for a long time without opening the bud which, when it does come, will be a great and probably a good Rose, while a much stronger shoot of three times its length perhaps opens quickly and produces a much inferior bloom. The shape of the smaller flowers is rather weak and undecided, but there is no doubt about its beauty in form and every other quality, when it does come good, though it is seldom very large. It does well as a dwarf, but is too small in growth to be called a free bloomer or good autumnal. There is certainly one, if not two, H.P.'s of this name.

Rubens (Robert, 1859).—The N.R.S. and a well-known northern exhibitor catalogue this Rose as “moderate,” but it is a famous grower with me, producing strong good clean shoots with very fine foliage, and quite capable as a short standard of covering the wall of a one-storeyed building. It is not liable to mildew, is slightly pendent, and can stand a little rain. The blooms come very well, but the petals are thin. The fine half-opened buds are grandly supported by fine foliage, but the flowers are not very lasting in shape, and are difficult to show well, as they look weak and unsubstantial when shown with other Teas. It does not do very well as a dwarf, and is best in cool weather; capital, early and late, against a dwarf wall; very free blooming and a good autumnal, thriving well on lightish soil.

Safrano (Beauregard, 1839).—Of very strong growth with fair foliage, not liable to mildew, and suffering very little in rain. Very free blooming, but a small and thin Rose, quite weak and open in the centre. It is only useful for buttonholes, and, like all thin Teas, is especially valuable in the late autumn. When not another Rose is to be found in decent condition anywhere from the cold and the wet, a *Safrano* on a wall will come to the rescue. Hardy, and of good constitution, and ready to grow anywhere. Of the same colour as *Rêve d'Or* and *Sunset*, but the buds have sometimes the lovely red tinge of *Madame Falcot*.

Souvenir d'Elise Vardon (Marest, 1854).—Not of free growth or good constitution, but there ought to be at least one pretty strong shoot to each plant, not liable to mildew, but subject to injury from rain. The bloom comes generally well, though sometimes divided, and when it is fine on a strong shoot, and is taken at the right stage, you have, to my thinking, the first and best of all show Roses, H.P. or Tea. It is getting an old Rose now, but nothing can compete with it. Mr. B. R. Cant

says in his catalogue, “Invariably takes the silver medal as the best Tea or Noisette,” and I think this is still true. To be sure the medal very often goes to another Tea, but that is because *Elise* is not there. It blooms early, as in fact do all the Teas, but these come again, while it takes a long time to work up fresh shoots to produce this grandest of Roses, and the second blooms never equal the first. Where the season is late enough for it to be shown in anything like perfection, no successful rival in any stand or competition has yet been found; and there will be an opportunity of testing this on June 24th next at the N.R.S. early Show of Tea Roses at the R.H.S. Exhibition. It does well as a dwarf, has fine foliage, and the blooms are of the largest size, and all that can be desired in every good quality. In freedom of bloom and as an autumnal it is not good, for the growth is shy and the constitution delicate. This is the Rose for enthusiasts, with whom one perfect glorious bloom is worth a garden full of ordinary flowers. And every possible care should be bestowed in watching and protecting the bud, and diligently and highly feeding the plant until the medal bloom, the Queen of the Show, is cut.

Souvenir de Gabrielle Drevet (Guillot, 1884).—Not of strong growth or foliage, not liable to mildew or much to injury from rain, does fairly as a dwarf, and comes very pretty and promising as a bud, but opens hollow, small, and disappointing. I had nearly made up my mind to discard it, but some useful buds in late autumn have obtained a reprieve for it for the present.

Souvenir de Paul Neyron, (Levet 1871).—Is generally catalogued as vigorous, but I find it weak as a rule with small foliage, though occasionally a plant will grow fairly well, and there is not much injury generally from mildew or rain. The blooms come pretty well, of a very good shape sometimes, and of large size considering the smallness of the stems, but the plant is difficult to please, and will not often do well as a dwarf. It is a poor autumnal, but very free flowering in the season, every wood bud all over the plant trying to grow as soon as the flower buds are formed. This habit, which which is more or less common to a good many of the free-flowering Teas of moderate growth, makes it very difficult to find buds for propagation without sacrificing some of the coming blooms. A good Show Rose in a Tea box when you can get it, but not a variety suited to the million.

Souvenir de Thérèse Levet, (Levet 1882).—Is also generally catalogued as vigorous and a free bloomer, but it shows neither of these good manners with me. It can stand some rain, and the foliage is pretty good, but rather liable to mildew. It often just escapes being a thoroughly well shaped Rose, and is remarkable for its colour, which is the deepest red of any of this section, but neither bright nor velvety, soon gets dull after being cut, and does not show well against the pure whites and yellows of its sisters in a stand of Teas. The size is only medium, but the shape is occasionally good, and it has all the lasting powers of its race. Perhaps it ought to be more cultivated, but most fanciers of Tea Roses seem half ashamed of it, as if it had no business to be red; and few, I think, would consider it had any claim to first-class quality. Note, there is a *Thérèse Levet*, a pink H.P., of some little merit.

Souvenir d'un Ami (Defougère, 1846).—A really good old Tea Rose, of strong, healthy, vigorous growth, with very fine foliage, not liable to mildew or much injured by rain. This is one of the hardiest of the pure Teas; does well as a dwarf or on light soil; a free bloomer and a capital autumnal, and the blooms generally come well, of fine shape, substance, petal, size, and lasting qualities. The principal fault is that the flower soon loses its colour, and is apt to look dirty, and I am therefore the more inclined to hope that its pure white sport,

Souvenir de S. A. Prince (Prince, 1889), which seems to promise all the good qualities of the type, may be not only quite as good, but even an improvement on the original.

Sunset (Henderson, 1883).—A sport from *Perle des Jardins*, of the same colour as *Rêve d'Or*; a handsome, useful, strong growing Rose, with foliage of a beautiful red colour when young. It seems to me to have rather better manners than its progenitor in the matter of coming well shaped in the summer, but to be just like it in every other particular except colour.

The Bride (May, 1885).—A pure white sport from *Catherine Mermet*, of great value. With me this Rose also is an improvement upon the type, growing better and producing a larger proportion of first-class blooms, but similar to it in general manners and customs. This is very high praise indeed, and some may be inclined not to agree with it. I have the Teas only as dwarfs, and in this, as in all other cases, I am speaking of Roses as I personally find them.

Many of my criticisms may appear strange to growers in other soils, climates, and situations, and if I have treated any Rose unjustly I hope it may find a defender to plead its cause in the pages of the Journal.—W. R. RAILLEM.

HORTICULTURAL BUILDINGS AND HEATING APPARATUS.

[A paper read by Mr. Henry Hope, horticultural builder, at a meeting of Birmingham Gardeners' Association.]

(Concluded from page 286.)

SPECIAL HOUSES.

I WILL now proceed to Tomato houses. This fruit of late years has become exceedingly popular, and tons upon tons are grown in the south of England and the Channel Islands, specially for the English market.

All who have the best experience agree that span-roofed houses are the best for Tomato culture. They may be built to almost any length (one house that I know of being 750 feet long by 14 feet high and 45 feet wide), it is a matter of question though that such large houses are advisable, as the attack of any disease means the probable infection of the whole stock, whereas in smaller houses it is not probable that more than one could be attacked at a time. For the sake of economy a large number of these houses that I have seen have been built without any side lights; but there is no doubt that side lights are an advantage. Ample ventilation is most necessary, and to obtain this a roof light about 3 feet deep at the apex on both sides, should open the whole length of the house; the whole of the front lights on both sides should also be opened. These, as I have said before, should be worked in long lengths, as a saving of time and labour. The interior fittings of a Tomato house vary according to its size; for small houses in which there is only room for one row of plants on each side, the roof should be wired horizontally, the wires being about 12 inches from the glass. In the larger houses no wires are necessary, the plants being placed in rows about 2 feet apart, each supported by a stake. The heating apparatus should always be a powerful one, the number of pipes of course depending upon whether the house is for early or late Tomatoes. Pine houses are best span-roofed, of a low pitch; side walls should be built about 3 feet high, and the roof placed upon them without any front lights. The ground inside the house should be excavated, to give sufficient head room, and a bed built in the centre for the Pines. Bottom heat should be provided by pipes under the bed, and top heat by pipes all round the outside walls. A few air bricks in the wall is all the side ventilation necessary, and a roof light on one side of the apex for top air.

Melon and Cucumber houses can be either plain, span-roofed, or lean-to, of small size, with or without side lights. The interior arrangements should be a pit with bottom heat and a lid for opening on each side. A span-house with a path down the middle, or, in the case of a lean-to house a path along the back wall. The roof should be wired horizontally about 12 inches from the glass.

Of plant and flower houses there are of course a great variety. The chief among these are Orchid houses, and the primary condition in construction is ensuring the full exposure of the plants to the light, with sufficient means at command to break the force of the sun in the hottest weather. Orchid houses should, if constructed of timber, be made only of the best seasoned material, put together in a thoroughly substantial manner. The large amount of moisture in the atmosphere very soon shows up bad timber or workmanship. The houses may be either span-roofed or lean-to according to convenience. The aspect is not of very much importance, though span-roofed houses should for choice run west and south, and lean-to houses for tropical Orchids should face the south, and for cool Orchids the north. Houses of moderate breadth and height are best for most Orchids, but *Cattleya* and *Laelia* thrive best in lofty spacious houses.

Ventilation in the front lights for Orchid houses is, as a rule, not required, a roof-light at the apex being generally sufficient. Ventilation in all cases should be provided through gratings in the front wall, with flaps to open and close as required, and the pipes should be placed in such a position as to allow the air to impinge upon them, thus obviating cold draughts on the plants. As moisture is a very important factor in the growth of Orchids means should be adopted for giving a plentiful supply. A very good method is by having a trench about 18 inches deep in the centre of the path with a grating over, this trench to be kept filled with water. Vapour is given off by this means at a much lower temperature than by troughs on the pipes, and as the vapour should not be at a higher temperature than the atmosphere the advantage of this method is obvious. With regard to the staging for Orchid houses I think that slate slabs three-quarters of an inch thick supported on bars is generally acknowledged to be the best. On this a layer of firm pebbles, spar, or shells is placed. These are kept constantly moist by syringing. Some place the pots directly on this layer of pebbles or whatever it may be, while in some instances a slight mould latticework is laid down, and the pots placed upon this. Any advantage though that may be obtained from this latter method is, I think, doubtful.

The blinds to an Orchid house are an important matter, and there are really only two good ways for applying blinds. The first is by a stationary spring roller at the top of the roof, round which the blind itself is wound; the second is by a roller, running up and down with the blind. These should be in as long lengths as possible by strong cords and pulleys, which if properly schemed can be linked either from the inside or outside the house, and with the greatest ease.

The materials used are sail cloth for very heavy shading, and screen cloth or tiffany for lighter work. The stuff should be thoroughly soaked in a solution of corrosive sublimate before being fixed; this will protect the material both from insects and the effects of damp.

Ordinary greenhouses, either span-roofed or lean-to, fitted with either iron and slate or wood lath stages, usually answer for the bulk of flowers and plants not included in those I have previously mentioned, and I do not think I need go into any details of this class. The remarks I have previously passed as to construction will apply to these. Finally, all horticultural buildings should be prepared and fitted at the works ready for erection, and painted two coats of good oil paint before being sent away, and the joints when fixing put together with red and white lead. A very large trade is done by several firms in what are called amateurs' greenhouses. These answer their purpose admirably provided they are kept as greenhouses, but a very frequent cause of failure is that some people when building a greenhouse not only think they can grow ordinary plants and flowers, but attempt to make one end of it a stove, and very probably try Vines on the roof. Compound houses are a mistake, and if only one house is put up the first thing to decide is what is to be grown in that house, and if more than one class of plants or fruits is desired more than one house must be erected.

EVENTS OF THE WEEK.—The chief horticultural event of the coming week will be the Daffodil Exhibition and Conference, to be held in the Royal Horticultural Society's Gardens, Chiswick, on April 15th, 16th, 17th, and 18th. An extensive display of Daffodils is expected, and much interest will be imparted to the meeting by the papers to be read by various authorities, particulars of which appear in another column. With regard to the Scientific Society meetings, the Quekett Club meet on the 11th inst., at 8 P.M.; the Royal Botanic Society, on the 12th inst., at 3.45 P.M.; the Royal Geographical Society, at 8.30 P.M. on April 14th; the Society of Arts, at 8 P.M., on April 16th; and the Royal Meteorological Society, at 7 P.M. on the same date.

— **COMMUNICATIONS.**—Owing to the pressure incident to the season (Eastertide) some communications with which we have been favoured cannot be inserted this week.

— **PROPOSED HALL OF HORTICULTURE.**—We are informed that the amount promised for this most desirable object is little short of £10,000. This is chiefly by amateurs, and an appeal, which we are bound to regard as a most reasonable one, is now being made to persons who are engaged in trades intimately connected with horticulture, and on the result of that appeal will largely depend the success of the project. There cannot be a doubt that the tendency of an important central hall of the nature suggested in the greatest commercial city in the world would be in the direction of trade development, because it would be an incentive to an increasing number of the wealthier portion of the community to engage in horticultural pursuits. It is hoped that there will be a good attendance of nurserymen, seedsmen, horticultural builders, engineers, and others, not of London only, but from the provinces, at a meeting to which they are invited to attend at 1.30 on the 22nd inst. at 117, Victoria Street, Westminster.

— **THE WEATHER IN THE SOUTH** during the past week has not been marked by any special characteristics. The N.E. winds prevailed the greater part of the time, but on Sunday there was a change to a westerly direction with rain; but on Monday the former direction was renewed, and on Tuesday there were several storms of snow, hail, sleet, and rain. Fruit trees are expanding their flowers, Pears and Plums especially, and in a day or two will be at their best. Peach trees on walls have flowered well in several cases, and there is promise of fair crops.

— **THE WEATHER IN THE NORTH.**—March 31st to April 7th. On three nights of the week frosts of 3° were registered, with heavy hoar frosts. Early planted Cauliflower, Pear blossom, and the blooms of Rhododendrons have suffered considerably. As a rule the days have been extremely fine, with bright sunshine. A cold wind from the north-

west sprang up yesterday, and still continues pretty high, and several showers have accompanied it. Temperature during the night 38°.—B. D.

— **GLUT OF POTATOES.**—The following paragraph has appeared in some newspapers: "There is an extraordinary glut of Potatoes in the Peterborough district, where the farmers have vast quantities on hand. The quotation they receive from the London markets is only 20s. a ton, and local prices, as a rule, range from 1½d. to 2½d. a stone." When a glut of inferior fruit is poured into the market it is made a pretext for condemning the production of superior samples, so we may now expect to be told how foolish it must be to continue growing Potatoes.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of this Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 16th instant, at 7 P.M., the following papers will be read:—"The Cold Period at the Beginning of March, 1890," by Charles Harding, F.R.Met.Soc.; "Note on the Whirlwind which Occurred at Fulford, near York, March 8th, 1890," by J. E. Clark, B.Sc., F.G.S.; "On the Possibility of Forecasting the Weather by means of Monthly Averages," by Albert E. Watson, B.A., F.R.Met.Soc.; "Rainfall of the Globe," by W. B. Tripp, M.Inst.C.E., F.R.Met.Soc.

— **GARDENING APPOINTMENT.**—Mr. H. May, late foreman at King's Ride, Ascot, as head gardener to Lady Keane, Rosemount, Sunninghill.

— **MR. GLADSTONE AT WEYBRIDGE.**—We are informed that the veteran statesman, when on a visit to Admiral Egerton last week, was taken by his guest to see Mr. G. F. Wilson's garden. He evinced much interest in what he saw, admiring the flowers greatly, especially the Oakwood Blue Primrose, that attracted so much attention at Westminster on Tuesday last.

— **THE SPARROW PEST.**—A correspondent, "B," writes:—"May I ask if there is any way known to keep down sparrows? My gardens are infested by them, and without nets it is impossible to grow Currants, Strawberries, or any kind of seed. Scarecrows are of no use. May I use poison in any shape?" We shall be glad if our readers can give the desired information.

— **SPRING FLOWERING PLANTS.**—Foremost amongst these, *Anemone appennina* deserves special mention, large beds of this very pretty species, of dwarf habit and pale blue flowers, yielding sheets of flowers under a wall with an east aspect, and close by is a large bed of *Triteleia uniflora*, a mass of flower of a shaded pale lilac and white colour. These masses are now in full beauty at Messrs. Thomson's Birmingham nurseries. *Ranunculus montanus* is another beautiful companion plant, a miniature Buttercup, now giving a profusion of golden yellow flowers.

— **DIVIDING HERBACEOUS PLANTS.**—Those who have to contend with a wet, heavy, and consequently cold soil during the winter months, will find the present a good time to increase these plants by division. Carefully cut through with a sharp edging knife, lifted with a fork, and planted quickly, they will start into growth at once, whereas if the dividing is done in the autumn little progress is made until the present time. The slugs, too, play havoc with the tender shoots which would just now be springing up through the soil. It is difficult to prevent this, for they prey upon the tender morsels just below the surface. It is a good plan to clear the growths and apply a sprinkling of soot about them, replacing the soil again.—E.

— **POINSETTIA PULCHERRIMA PLANTED OUT.**—I lately saw in a small lean-to house, the front part of which is devoted to Melons during the summer, the Poinsettia planted in a narrow border at the back, the branches being trained against the wall, the main stems in a horizontal manner. This season twenty-five heads were produced, which were large and richly coloured, their appearance being considerably improved by the ample deep green foliage with which the plant was covered. Some of the shoots had grown 5 feet long from the base where pruning was done the year previous. At the present time many small bracts are pushing from short side shoots, which are being forced from the joints since the main blooms were cut. To obtain strong growth and subsequently strong bracts the current season's growth should be cut in to within one or two eyes of the base, as in the case of allowing a considerable extension of last year's growth with a view to extend the size of the plant in any direction growth is not nearly so freely or strongly made, but by concentrating the whole energy of the plant into fewer branches more strength is given to subsequent growth and finer bracts. Abundance of water to the roots while growth is active is beneficial, and indeed necessary.—M.

— **DEATH OF MR. MICHAEL MIDDLETON.**—Mr. M. Middleton late gardener at Admiralty House, Bermuda, died of consumption at Hamilton of that place on the 26th February last at the early age of forty-four. Twenty-one years ago Mr. Middleton was one of a group of about a dozen young men, then students in the Royal Gardens, Kew. This group consisted of Englishmen, Scotchmen, Irishmen, one Welshman, two Germans, and one Dane. They were contemporary with Mr. Kingston, who fell a victim to his love of botany in the Herbarium not many years after, with Mr. R. I. Lynch, now of the Cambridge Botanic Gardens. They sat at the same examinations both at South Kensington and for the Society of Arts, and Mr. Middleton was not the least successful among his compeers. These young men were soon scattered. Three went to India; one I last heard of in a good position in America; the Germans went to fight for their Fatherland, and have not been heard of again by the writer; the Welshman took to preaching, and others to various parts of the United Kingdom. After some few years' experience in gentlemen's places the late Mr. Smith showed his confidence in him by getting him to take the place of a sick foreman for some time, and afterwards recommended him to General Lefroy, with whom he went for a term of five years while he was Governor of Bermuda. At the end of that time he returned to England with his master, and was for a short time with a gentleman in his native county of Northumberland. He afterwards went to America and in various parts of the States as far west as Dakota, where his health broke down, and was advised to seek the more salubrious climate of Bermuda. After recovering from his illness he was appointed to the Admiralty Gardens, where he was till shortly before his death.—R. INGLIS.

— **A BEAUTIFUL HANGING BASKET.**—During a recent visit to Childwall Hall, Liverpool, I was particularly struck with a basket filled with *Lachenalia pendula*. This grand old occupant of our greenhouses it would be impossible to see to greater advantage, the basket in question being about 2 feet wide by 2½ feet deep; the whole perfectly draped with graceful foliage and spikes of bloom a foot long. Those who have not seen *Lachenalias* grown in this way can form no conception of their almost matchless beauty. Mr. Winkworth proposes exhibiting this plant at the Spring Show of the Liverpool Horticultural Association, and if staged in the perfection I saw it, will prove a striking feature.—VISITOR.

— **THE WEATHER LAST MONTH.**—March was cold and wintry for the first five days. The minimum temperature on the 4th (12°) was the lowest we have any record of for March, and the lowest this winter here. The remainder of the month was bright weather on the whole, with the exception of 18th to 22nd. Highest shade temperature was 62° on the 17th, lowest 12° on 4th; lowest on grass 12° on 4th. Barometer.—Highest, 30.60 at 9 A.M. on 3rd, lowest 29.13 at 9 P.M. on 24th. Rainfall.—Total, 2.23 inches, which fell on eighteen days, and 0.68 inch of which fell on the 19th. Wind was in a westerly direction twenty-five days during the month. The garden spring ran 23 gallons per minutes on 31st.—W. H. DIVERS, *Ketton Hall, Stamford*.

— **SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR MARCH.**—Mean temperature of month, 43.6°. Maximum on the 12th, 62.2°; minimum on the 4th, 19.7°. Maximum in the sun on the 26th, 116.0°; minimum on the grass on the 4th, 12.6°. Mean temperature of the air at 9 A.M., 44.1°. Mean temperature of the soil at 1 foot deep, 41.9°. Nights below 32°, in shade ten, on grass seventeen. Total duration of sunshine, ninety-four hours, or 26 per cent. of possible duration. We had five sunless days. Total rainfall 1.72 inch; rain fell on twelve days. Average velocity of wind, 13.8 miles per hour; exceeded 400 miles on eight days, and fell short of 100 miles on one day. Approximate averages for March—Mean temperature, 41.8°; sunshine, ninety-eight hours; rainfall, 1.61 inch. A mild month, with average rainfall. The mean temperature is higher than in any of the last fifteen years, except 1882. Vegetation very forward.—JOSEPH MALLENDER.

— **FISHES IN A FOUNTAIN BASIN.**—I have a fountain basin in my garden about 14 feet diameter and 2 to 3 feet deep; a quantity of a filamentous weed grew in it, which kept the water very clear and bright; but it grew so thick, and the basin had not been cleaned out for so long, that I determined to clean it out, which I did. I threw back a small quantity of the weed, thinking it would grow again, but it did not, and now I cannot see the water clear. I have Lilies and other water plants, but they have not the same effect. I should be glad if you would kindly tell me the name of the weed. I fancy it is what is called the American Pond-weed, which grows so rapidly, and chokes up canals, &c., in some places. I may add that the golden orfe is a capital

fish for keeping in such places. I put nine in about two years ago, and have not lost one. They are very lively, and apparently hardy. Gold fish I cannot keep any length of time. The small Prussian carp do very well, and breed.—B. [The weed referred to is probably *Anacharis alinastrum*.]

— **STAPHYLEA COLCHICA**.—At a recent meeting of the Birmingham Gardeners' Association, when Mr. Groves read a paper on "Insect Pests," Messrs. Hewitt & Co. exhibited a plant in full flower of this charming hardy shrub in a forced state, but the "forcing" was of a very mild character. These plants are kept under glass to make early growth, taking care to keep the shoots short by pinching when necessary, and the roots confined to the pots, plunging them out of doors to secure a well ripening of the wood. The plants are placed in a cool house during the winter, and are gradually brought on in moderate warmth. At Solihull they had a supply for Easter, and the *Staphylea* will, when better known, be much in demand as a decorative plant and for cut flowers.—D. S. H.

— **THE READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION**.—A well attended meeting of this Association was held on Monday, the 31st ult. Mr. W. Leas occupied the chair. After the usual business had been disposed of Mr. George Cannon of Ealing read an able paper on "The 'Outside' Cultivation of Roses." Having referred to the early history of the "Queen of Flowers," and its popularity among the Greeks and Romans, Mr. Cannon traced the progress made in culture and in the raising of new varieties during the last fifty years, and gave lists of varieties found most suitable for various purposes. He also gave sound advice on the selection of stocks for different soils, and clearly explained the details of culture requisite in order to achieve the best results. A discussion followed, and Mr. Cannon was warmly thanked for his practical paper. A fine healthy specimen of *Angræcum sesquipedale* was exhibited by Mr. Woolford, one characteristic of this variety being the long tail depending from the base of the flower.

— **MESSRS. SUTTON & SONS'** valuable work on the "CULTURE OF VEGETABLES AND FLOWERS" has reached a fourth edition of 5000 copies, 13,000 having been sold of previous issues. This is a remarkable circulation for a work of this size and character. It is a substantial well bound volume of 410 pages, including an excellent index. The practical matter occupies 402 pages, and is as good as the paper and print on and by which the various cultural details are represented, and that is saying a great deal. Vegetable growing is made plain, and no one can err in following the instructions. Similar remarks apply to the cultivation of all the popular kinds of flowers. A chapter is devoted to the formation of lawns from seeds, also to insect and fungoid enemies, admirably illustrated. It is a standard work for the libraries of professional and amateur gardeners.

— **WEeping ASH AT NOSTELL PRIORY**.—There is a very large and beautiful specimen of the Weeping Ash growing in the grounds adjoining the garden at Nostell Priory, the seat of Lord St. Oswald, near Wakefield, Yorkshire. Its measurements, taken a few days ago, are as follows:—The girth of the stem at 2 feet from the ground is 7 feet—the narrowest part of the stem; at 4 feet up it is 7 feet 3 inches in girth; and at 6 feet up it is 8 feet 6 inches. At this height the branches begin to spread upwards and outwards till they reach a total height of about 50 feet, and a diameter of 67 feet the broadest way through them, the top being considerably flattened at the sides by the proximity of the agent's house on one side, and a fine Holly hedge on the other. When in full leafage in the summer season it affords a cool shady retreat, and forms an exceedingly graceful object—a miniature mountain of greenery—in the beautiful grounds around the Priory, one of the many fine old family seats so numerous in the district of Yorkshire.—J. H.

— **BOUVARDIAS**.—When I penned the few lines relative to planting out Bouvardias, which appeared at page 156, I did so more with a view to show that good results could be obtained by the practice than to criticise Mr. Bardney's excellent article on their culture entirely in pots, page 12. I had no wish to convey the idea that better results could be achieved by the method I described, a method which he pronounces "excellent in every way, &c." (I thank him for the compliment), but why he should in the next paragraph proceed to question the soundness of the practice, or part of it at least, is to me not quite clear. I place out these and other plants during the summer to save time and labour in watering, for in these days when much is expected and often but slender means allowed to accomplish it, any help, however small, which will enable an overworked brother gardener

to produce what is required with less labour than formerly, is a step in the right direction. As Mr. Bardney wishes to know why I partially lift the plants a fortnight ago or so before potting, I may say that I do so in order to ensure (as he rightly supposes) a more compact ball of roots; and I water and syringe to prevent a serious check taking place through the operation. I do not say that they receive no check—they must; nor would I undertake to transfer a strong, healthy plant of anything from the open ground to a pot without a check; but I think it need be but a very temporary one, and therefore not of a "serious" character. A method that will afford strong bushy plants with an abundance of flowers at a minimum expenditure of labour is surely worth a trial where the situation is suitable. Were I as far north as your correspondent, I certainly should not turn out the whole of my stock.—T. S., *Henbury Hill*.

— **BIRDS AND FRUIT TREES**.—Although a lover of birds I am forced to the conclusion that the sparrows are more numerous and destructive than profitable. I regret to have to say this of them, as sometimes they are the gardeners' friends. I always find that birds are most destructive to fruit buds during rainy and open weather. In times of drought they do little harm. A proof of that is afforded this year with us, not a single fruit bud of the Victoria and other Plums has escaped them. The blue tit (Parus minor) is as bad as the sparrows. Red and White Currants are almost as badly attacked, and Gooseberries are much spoiled, even the Morello Cherries did not escape. What is the cause of so great an increase of sparrows, and I may add mice and rats? I answer the wholesale destruction by gamekeepers of the natural enemies of vermin, such as owls, hawks of sorts, and all the weasel tribe.—W. T.

— **FRANCISCEAS**.—I find these very useful plants and a hint on our present treatment may be useful. We prune them back to within a few eyes from where they started last year, and place them in brisk heat. After they have commenced growth they are repotted if they need it. If the plants are already in pots large enough, and the drainage is good, feeding with weak stimulants may be resorted to. If the drainage is defective and the soil in an unsuitable condition turn out the plants, and carefully work from amongst their roots a good portion of the old soil, and repot the plants in the same size with equal parts of peat and fibry loam with a liberal addition of sand. These plants will do very well in either all peat or all loam and sand, but the mixture appears to suit them admirably. The soil should be pressed firmly into the pots, and where practicable plunge the pots in gentle heat until root activity has commenced. The plants must be watered carefully at first.—N. G.

— **ALLAMANDAS**.—When grown in pots the roots of those needed for flowering early may be reduced by one-half, and returned to the same size pots. If dry soak them in tepid water, and allow them to drain thoroughly before potting them. Use a compost of fibry loam, one-seventh of manure and sand, and press it firmly into the pots. The plants afterwards may be stood in the stove, or better still plunged in slight bottom heat, and syringed freely until they start into growth.

— **PLANTS OF ADIANTUM CUNEATUM** that have been cut over and rested in a temperature of 50° should be pushed into growth. If they are in pots as large as it is advisable to have them in, they may either be cut in two or the roots reduced. The last method is the best, as the plants quickly start again into growth, and produce large fronds long before the others. Where it is possible give the plants a shift into larger pots. The pots should be liberally drained, as the plants root abundantly near the surface. The new soil may be pressed moderately firm into the pots, so that the old soil will not be left dry by the water passing through the lighter material. These plants do better without peat than with it in the compost. We have long since discontinued its use. They grow remarkably well in loam and sand, but not so rapidly as in a lighter and more open compost. Where leaf mould that has been well prepared is plentiful, nothing better can be used, with the addition of sand, lime rubbish, or any gritty material. Our compost consists of one-third loam to two-thirds leaf mould and lime rubbish. They grow freely and root splendidly in this compost, which remains perfectly sweet when plenty of lime rubbish is added. If slugs exist about the crowns, dust them with soot, and the slugs can soon be picked off. Place the plants after potting in a temperature of 60°.—B.

— **THE BOG GARDEN AT HIGH BEECH**.—I was very pleased to read in a recent issue of the Journal that Mr. G. Paul considers his bog garden a success. I feared it would be otherwise. This particular spot has always been an object of interest to me. I well remember its con-

struction, and at that time I had a keener interest in its welfare than its owner. It was in my early gardening days, but at date I was allowed the free run of the nursery, and many a useful lesson have I learned therein. At one period I had a list of the whole of the occupants of the garden. During the last four years I have only been able to pay occasional visits, but I must confess I have lost interest in many of the occupants of the various corners and pools, for to appreciate bog plants one must be in constant association with them. In my last visit I noticed many new occupants, and missed many old friends; but I suppose it is the same in every garden—gaps in the ranks will appear. At present everything seems springing into life. The excellent collection of *Calthas* are blooming, except the later forms, such as *purpurascens* and *monstrosa*, but they will be better in a fortnight. The *Orchises* are starting very vigorously. *Primulas denticulata* and *japonica* seem to be the only species that are really at home. I do not remember seeing *japonica* flower better than in this bog garden. The other species is in full flower at the present time. The *Winter Hawthorn* thrives splendidly in the pool, and flowers freely, even in November. The *Spiræas* are perfectly at home, so are the *Sarracenias*. These interesting plants are always worth a careful study. The *Azalea mollis*, planted on the bank surrounding the garden, caught my eye; they are literally a mass of flower buds. *Irises* are successful here speaking generally, and they flower most freely. The various *Rushes* also thrive very well, but I must take adieu of the garden for the present.—JAMES B. RIDING.

—HYACINTHS AT DUNEEVAN.—The beds of these, which are a prominent feature in Mr. McIntosh's beautiful and highly kept garden every spring, are now in full beauty. There are about a dozen beds, the central one displaying about a thousand spikes. Each is supported as neatly as if the plants were grown in pots, and more neatly than they are often seen in greenhouses, the stakes being of galvanised wire. The *Hyacinths* are in mixture, two-thirds of them single and one-third double varieties, the employment of the latter giving a massive appearance to the display. The beds were broadly margined with *Crocuses*, the green arching leaves of which form a pleasing fringe to the flowers they encircle. *Tulips* are advancing, but, like many others we have seen, are not likely to quite reach the usual standard of excellence, and judging by what we have heard these flowers have not, as a rule, been so good in greenhouses as was hoped for. There is good promise of *Rhododendrons* at Duneevan, where the collection is choice and extensive, and similar remarks apply to the hardy fruit garden, which contains many model trees well studded with blossom buds. All who have the pleasure of Mr. McIntosh's acquaintance will rejoice in his improved health; and though he cannot, as was his wont, traverse his grounds daily, with wild birds following him to be fed, they come to his windows to see what he has for them, and whichever room he occupies find him out. Thrushes, robins, finches, nuthatches are alike on friendly terms, but do not quite equal the robin that we have seen rest in his beard and take crumbs from his mouth. The Duneevan grounds and gardens always reflect credit on Mr. T. Taylor, who has had charge of them for about twenty years.

FLORAL NOTES IN SEASON.

AFTER TREATMENT OF BULBS.—If bulbs grown in pots are intended to be used next year for pot culture or flowering out of doors they must be thoroughly ripened, fully exposed, and grown continuously without a check of any kind. The custom is, when flowering is past, to throw them aside, to become either water-logged or as often dried at the roots before half the growth has been completed. Of all the methods of treatment after flowering for *Crocuses*, *Hyacinths*, *Narcissi*, *Irises* (especially *reticulata*), *Dielytras*, *Tulips*, *Hepaticas*, the Chinese "Joss" or Sacred "Lilies" (*Polyanthus Narcissi*), &c., I find the best is to plant them in a warm sunny border. If that is not convenient, as in many town gardens, then sink the pots to the rims. If that cannot readily be done either, greater care in watering—giving a stimulant of some of the advertised manures liquified now and then—is indispensable. The bulbs can be shaken out where the foliage has withered.

FUCHSIAS.—It would be a pity to allow the sun of their popularity to grow dimmed through the temporary attraction of something not half so good, though labelled "new." Remove them from under the stage or potting shed, or wherever stored, if not already done. Shake out the old soil, repotting in a fairly rich mixture of yellow loam with a little sand, and place them in a warm temperature until they break. Sun heat alone will be necessary after growth has started. Cuttings with me taken last autumn of good varieties are coming into flower now. To secure a young stock to form handsome plants for the autumn, cuttings taken now, if possible at a joint, inserted in a sandy medium—all the better covered with a bellglass, and with a temperature of at least 55° Fahr.—will be rooted in a few weeks, and may be potted into a somewhat

poor sandy loam at first, to prevent a too luxuriant growth during the summer months.

DAHLIAS.—Those lifted in the autumn—and I have found, though our winters are comparatively mild, it is best and safest to lift good named varieties—will now be slowly moving, even under a greenhouse stage, where little or no forcing has been resorted to. Amateurs not having proper facilities for striking cuttings will easily increase their stock by division of the tubers, always making certain of having a couple of eyes. Cuttings root best in silver sand, on a hotbed, and with a temperature of 70°, or near it. As the cuttings progress they will be repotted and kept as cool and as stocky as possible. Long and spindly growth spoils the chances of fine flowers. Single Dahlias have not maintained their popularity, while those of the Cactus and decorative varieties are steadily competing with the show and fancy sections. Those wishing to raise new varieties, or to observe the effects of hybridising, will be sowing seed, if they have not already done so. There is always a peculiar zest in watching the progress of seedlings, and all the more if they have been home-raised.

SPARMANNIA AFRICANA.—Of Cape origin, this is far easier to succeed with than many floral beauties from that colony. It is almost hardy, and if properly ripened in the full sunshine in summer and autumn, flowers the whole winter with ordinary greenhouse treatment. The stems may be cut back now, and the cuttings rooted to form young plants; but it is only in the second or third year its long-continued flowering peculiarities are fully developed. It is unlike any other flower, inasmuch as it is the peculiar bunch of feathery looking stamens and not the corolla that attracts most attention, while it will contrast, either in foliage or flowers, with any other occupant in the conservatory. On occasions it is admirable for dropping into vases for decorative purposes.

PRIMULA OBCONICA.—I am under obligation to say a good word for this accommodating Primrose, inasmuch as it has proved a continuous flowerer in my greenhouse, sitting room, and windows, since last autumn, and still the flower spikes increase and multiply. It would have been a gross blunder had the cry that "poisoning" resulted from touching the leaves, scared people away from growing it. I am constantly touching it, and yet I have found no inconvenience therefrom; but this is not meant to discredit those who have stated their experience is otherwise. I have found it responds readily, like *Primula Harbinger*, *P. rosea*, and *P. marginata*, to diluted liquid feeding, but more so than any other. From this time forward after flowering will be a good time to divide the crowns where an increased number of plants is desired. A good precaution is not to overpot.

DOUBLE PETUNIAS FOR GREENHOUSES.—Except with peculiar facilities for protection from rough weather and slugs, I am for wholly growing these indoors. They are so beautiful and rich in colour, grow so large and unwieldy, and are produced in such profusion, that I consider them too good for ordinary outdoor culture. Take those delightful combinations of green, rose, purple, lilac, white, crimson, rosy magenta, &c., some crimped, folded, fimbriated, suffused, veined, edged and tipped, or with a number of those characteristics in the same flower, and tell me if you know any other flower, except some of the *Cattleyas*, so curiously attractive. My advice to anyone having a greenhouse is to get some good named varieties well rooted just now, rather than depend on the chance of raising a number of worthless seedlings, all inferior to named sorts, and give them at first small pots until these are full of roots. A 4½-inch pot will be ample the first year if liquid feeding is resorted to, and as in my case, blooms may be guaranteed for nine months out of twelve. If large specimens are desired the plants can be shifted accordingly. A distinct dozen would be *Rubens*, *M. Buchner*, *Labyrinth*, *Crimson King*, *Aida*, *Mrs. Shirley Hibberd*, *Fimbriata*, *Delicata*, *Telephone*, *Madame Sawyer*, and *Lady Lorne*. By taking cuttings now and then a stock is continuously maintained, not merely the year round, but in perpetuity.—W. J. MURPHY, *Clonmel*.

LELIO-CATTELEYA HIPPOLYTA.

THE list of Veitchian hybrid Orchids is still steadily extending, and scarcely a meeting of the Royal Horticultural Society's Committees passes without some newly flowered production making its appearance on the tables. At the gathering in the Drill Hall on March 25th last a bigeneric hybrid bearing the name given at the head of this note was exhibited and unanimously certificated by the Committee. It was stated to be the result of a cross between *Cattleya Mossiae* and *Laelia cinnabarina*, both well known Orchids, and it was comparatively easy for anyone familiar with the parents to trace their relative influence. The *Laelia* has undoubtedly very greatly predominated both as regards the shape and colour of the hybrid, but the *Cattleya* has exerted a modifying effect chiefly upon the colouring, and the result is a uniform soft and distinct orange

buff shade, brighter and more lovely than "buff" tints are usually, but totally distinct from the peculiarly rich orange red of *Lælia cinnabarina*. The flowers of the hybrid have a graceful outline, the narrow sepals and petals spreading equally; they are nearly 5 inches in diameter from tip to tip of the sepals, the latter being half an inch in diameter and of equal width throughout. The petals are just over 1 inch across at the widest part, tapering slightly both to the base and the point, and this difference between the sepals and petals furnishes a ready mark of distinction between the present hybrid and *Lælia flummea*, derived from *L. cinnabarina* and *Lælia Pilcheriana*, in which the divisions are of equal size. The lip has a partially closed appearance, like *L. cinnabarina*,

that the resemblance is chiefly in the shape of the lip. The sepals and petals are very distinctly spotted with violet purple on a yellowish ground colour, and the heavy purple parallel veins in the lip are a marked feature.—L. CASTLE.

HIPPEASTRUMS AT CHELSEA.

THOUGH still familiarly known as Amaryllises in many gardens, the plants denoted by the title *Hippeastrum* are gradually becoming identified with their correct designation, notwithstanding the fact that this is decidedly less euphonious than the superseded name. Still the differences between the two genera are so clearly marked, that the distinction

FIG. 38.—*LÆLIO-CATTELEYA HIPPOLYTA*.

and it has a slight suffusion of crimson at the tip and in the throat.

DENDROBIUM ATRO-VIOLECEUM.

As described in the report on page 304 this *Dendrobium* is one of the most distinct yet introduced, and though it cannot be regarded as one of the most beautiful it yet possesses some claims to attention for its peculiarity of colouring. The plant submitted to the Orchid Committee on Tuesday was not in good condition—indeed, the impression seemed to be that it was an imported plant with just sufficient strength to produce its flowers, and that its life was nearly exhausted; at least there was no sign of growth, and the pseudo-bulbs had no leaves, and it was owing to this probably that the first-class certificate proposed for the plant was lost by a small majority. The flowers remind us at first glance of *D. Veitchianum*, the true *D. macrophyllum*; but on closer examination it is seen

should be observed, even in popular horticultural nomenclature. In Mr. J. G. Baker's excellent monograph of the Amaryllideæ, the genera named are placed in different sections of the order, and while thirty-eight species of *Hippeastrum* are described, the genus *Amaryllis* is reduced to one species, the garden favourite *A. belladonna*, which ranks next to the *Crinum*s, and is distinguished botanically from the *Hippeastrum*s by characters derived from the capsule and seeds. Under the *Hippeastrum*s are ranked the comparatively few species that have been concerned in the production of the present beautiful race of hybrids, which, in stately and imposing form, brilliant colours, and decorative value, are probably unsurpassed. The history of the gradual development of these handsome plants has been previously related in this Journal, and it is not necessary to repeat it, but it is worthy of remark that only about a dozen species have been employed, the first to be so utilised being *H. reginae* and *H. vittatum*, which Mr. Baker tells us were first crossed in 1799 by a watchmaker at Prescot named Johnson, and from these, with other species, numbers of hybrids were raised, and no

less than 100 with Latin names were enumerated in Sweet's "British Flower Garden" in 1830.

It is only within the past twenty years, however, that the greatest progress has been made, and previous to then the flowers of the hybrids raised were much smaller, and in most instances greatly inferior in form and colour to these we now have the opportunity of admiring. Much credit is due to Messrs. J. Veitch & Sons of Chelsea for the attention they have given to the Hippeastrums, and the results they have achieved in recent years have been amply sufficient to satisfy all who are interested in the improvement of plants. At a meeting of the Royal Horticultural Society a short time since a group of these was shown, together with some of the earliest forms to illustrate the advance that had been made, and the contrast was most striking. It is only by means of comparing the extremes of variation in a class of plants that an adequate idea can be formed of the progress made. We become familiar with the improved types, and do not so readily realise what has been done to effect this improvement. At Chelsea for the past few weeks the Hippeastrums have been in fine condition, and they will continue attractive for two or three weeks more, a sufficient indication of their lasting qualities. A commodious span-roof house is devoted to them, a central and two side beds being filled with bulbs, and there are over 2000 spikes bearing expanded or expanding flowers. It is quite a forest of spikes, and the large flowers of the most brilliant shades of scarlet are quite dazzling on a bright sunny day. It would be unnecessary to enumerate all the varieties represented, though all are beautiful, still there are differences which render some of them easily distinguishable and unquestionably superior to the others. So large a number of seedlings also have been raised that novelties are constantly appearing, and scarcely a day passes without some addition being made to the already long list of those found worthy of names. A few of the principal novelties of the present year are briefly described in the following notes.

Champion.—A magnificent variety of the Empress of India type, the flowers exceeding 10 inches in diameter, the divisions $3\frac{1}{2}$ inches across, and slightly recurving, giving a distinct character to the flower. The colour is a most brilliant shade of scarlet, and the variety appears to be a strong one, the bulb bearing two fine spikes. It has been certificated by the R.H.S. this year.

Lacina.—A delicately pretty variety, the flowers white with a few rich crimson streaks in the upper divisions.

Attraction.—A finely formed flower, with broad divisions, crimson scarlet, and a white central bar.

Dromio.—A particularly rich deep shade of scarlet, unbroken up to the centre; the flowers of moderate size but excellent shape, and a fine contrast with the lighter varieties.

The Kaiser.—Flower of excellent shape and substance, the colour a light, clear, bright scarlet, very effective.

Ossidine.—Light scarlet, a clear white bar in the centre of the division, the flower of excellent shape.

Aganora.—A superior variety of the Dr. Masters type, rich deep scarlet, large flowers.

Egeria.—Salmon scarlet, a distinct and pleasing tint, the flowers well formed, a white bar in the centre of the divisions.

Cypria.—One of the champion type, flowers of capital shape, the colour a rich scarlet.

Keraunos.—Light scarlet, broad white central bar in each division, free, four flowers in a spike.

Aeanthea.—A neat flower, bright scarlet, with a white central star; effective and distinct.

Eros.—Flowers of good shape, boldly veined with scarlet on a white ground, and with a white central bar in each division.

Haidee.—Rose scarlet, a warm and distinct shade of colour, the divisions very broad. A handsome novelty.

Arion.—White suffused with a rosy tint, and veined with a similar colour.

Attila.—A pale delicate tint of salmon, with white central bars and base. One of the most distinct of the light coloured varieties.

Dorothy.—Excellent shape, veined scarlet on white. A graceful flower in poise and shape.

Ino.—A charming variety, evenly and boldly veined with scarlet on a white ground. Very free.

Those named are all seedlings that have flowered for the first time this year. In addition to them there are the many handsome varieties of recent years, and amongst the best of these may be noted Her Majesty, Illustrious, Nemesis, Mirabella, Aureole, Exquisite, Marcellus, and King Lear as possessing prominent attractions, but there are numbers of others equally as good.—VISITOR.

ROYAL HORTICULTURAL SOCIETY.

APRIL 8TH.

THOUGH following the holidays so closely the meeting on Tuesday was very interesting, the exhibits of plants and flowers being varied and bright in a more than ordinary degree.

FRUIT COMMITTEE.—Present: Sir Charles W. Strickland, Bart., in the chair, and Messrs. T. Francis Rivers, R. D. Blackmore, P. Crowley, J. Smith, H. Balderson, A. Watkins, W. Warren, G. Wythes, J. Hudson, J. Smith, and J. Wright. Their duties were light, as is usual at this period of the year.

Splendid fruits of Auguste Nicaise Strawberry were brought by Mr.

J. Smith from Mentmore. They were equal in size and appearance to first-class British Queens grown in the open air. The variety is extensively grown in pots by Mr. G. Wythes at Syon, also by Mr. J. Challis at Wilton. An award of merit was adjudged to it as a good variety for forcing. It is not considered generally reliable for outdoor culture. Mr. Smith also sent excellent fruit of Nohle, but not equal to those of Auguste Nicaise. Mr. W. Miller sent large basketfuls of fine Mushrooms, and was accorded a vote of thanks.

A dozen varieties of Broccoli were brought from the Society's Gardens those which found the most favour with the Committee being Cooling's Matchless, Leamington, and Mammoth (Veitch), the White and Purple Sprouting varieties were also considered useful vegetables.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., Messrs. R. Dean, Shirley Hihberd, T. Baines, H. Herbst, D. T. Drury, T. W. Girdlestone, P. Blair, H. B. May, R. B. Lowe, D. Jeffries, B. Wynne, G. Paul, and the Rev. H. H. D'Omhain.

From the Royal Gardens, Kew, came a collection of hardwooded and decorative plants, such as are just now employed with excellent effect in the greenhouse at Kew. Some of the most notable were *Chorozema Soulangeanum*, with orange and crimson coloured flowers, produced very freely; *Eupatorium atro-ruhenis* is remarkable for its large heads of purplish flowers; the white-flowered *Eupatorium probum* was also shown; the purplish *Tetralochea pilosa*, the scarlet-flowered *Agapetes huxifolia*, the bright yellow *Goodia lotifolia*, a small plant of *Mackaya hella*, several *Grevilleas*, *Polygalas*, *Eriostemons*, and *Agathosmas* were included. D. T. Hodges, Esq., Lachine, Chislehurst, had a group of Primulas, including several pretty species (bronze medal).

Messrs. Paul & Son, Cheshunt, contributed a handsome collection of plants, comprising a large number of Primulas, *Doronicum plataginifolium* excelsum, an excellent variety; Daffodils; choice hardy plants comprising several Gentians, Tulips, and several *Berberises*, amongst them being a hybrid from *B. Aquifolia* and *fascicularis*, "selected for some years for its early flowering habit and fine trusses of flowers." It has bright yellow flowers and leaves like *B. Aquifolia*. A group of varied brilliant Hippeastrums completed the collection, for which a silver Banksian medal was awarded. Mr. W. Roupell, Harvey Lodge, S.W., sent a plant of an Auricula to show the reversion from the show type to the earlier forms. Mr. W. Rumsey, Waltham Cross, showed a box of pale and bright Rose hlooms (vote of thanks). He also had a group of Roses in pots well flowered (silver medal).

Messrs. Rothschild, Gunnersbury House, Acton (gardener, Mr. F. Hudson), sent flower sprays of *Hahrothamnus scaber* (Newell) with trusses of light red flowers, and flower stems of *Maranta Warscewiczii* and flowers of *Magnolia conspicua*. The Rev. W. Wilks, Shirley Vicarage, Croydon, sent sprays of *Cytisus purpureus* (C. Adami), obtained from grafting the purple on the common *Lahurnum*. Mr. F. Wilkins, The Grange Gardens, Kingston Hill, showed a basket of fine Primroses (vote of thanks).

Messrs. Barr & Son, King Street, Covent Garden, showed a large collection of Narcissi and hardy flowers. Mr. R. Dean, Ealing, exhibited several Primroses of distinct colours. From Mr. J. Walker, Ham Common, Surrey, came a grand group of Daffodils in many varieties and admirably staged (silver medal).

ORCHID COMMITTEE.—Present: Dr. M. T. Masters in the chair, and Messrs. D. B. Crawshaw, H. M. Pollett, H. Ballantine, C. Pilcher, J. Dominy, E. Hill, Lewis Castle, Sidney Courtauld, J. Douglas, A. H. Smee, James O'Brien, T. B. Haywood, and Baron Schröder.

F. G. Tautz, Esq., Hammersmith (gardener, Mr. Cowley), exhibited a small group of Orchids in flower, *Cypripedium selligerum majus* with four fine flowers being very notable. Mrs. Brightwin, The Grove, Stanmore (gardener, Mr. J. W. Odell), sent a plant of a small flowered, pale mauve, or white *Disa*, named *sagittalis*. It is said to last eight weeks in flower. F. Wigan, Esq., Clare Lawn, East Sheen (gardener, Mr. W. H. Young), showed a group of Orchids comprising several *Cypripediums* and *Cattleyas*, *C. Trianae Schoderæ*, with soft purplish mauve flowers, being the most remarkable, and it had twelve flowers on four spikes. *Aeranthus Leonis*, well flowered, was awarded a cultural commendation.

Mr. P. Blair, Trentham Gardens, Stoke-on-Trent, contributed a collection of choice Orchids, *Dendrobium nobile nobilissimum*, *D. chrysodiscus*, *D. nobile Cooksoni*, *Odontoglossum flaveolens*, and the Trentham variety of *Odontoglossum Ruckerianum*, with deeply spotted flowers, were conspicuous (bronze medal). The Rev. H. Handley, 19, Royal Crescent, Bath (gardener, Mr. S. Veersteke), exhibited a plant of *Angraecum sesquipedale* with seven large flowers, a large-flowered variety of *Odontoglossum crispum* and *O. maculatum*. E. Ellis, Esq., Manor House, Wallington (gardener, Mr. T. A. Glover), sent a plant of *Aerides suavisimum*, with four spikes of flowers, pale pink sepals and petals, and large fleshy yellowish lips (cultural commendation). Messrs. J. Laing & Sons, Forest Hill, showed a small plant of *Cypripedium niveum*, with a white flower dotted with purple, like *C. Godefroyæ*.

Messrs. J. Veitch & Sons, Chelsea, sent a plant of *Dendrobium atro-violaceum*, a native of New Guinea, with leafless slender furrowed pseudo-bulbs, and creamy coloured sepals and petals densely spotted with deep purple. The lip is green, closely and heavily striped with dark purple. They were borne in a short raceme of six flowers at the apex of the pseudo-bulb.

CERTIFICATED PLANTS.

Hippeastrum Grand Monarch (James Veitch & Sons).—A magnificent variety, the flowers of excellent form, and the colour an intensely rich dark scarlet to the centre.

Primrose Oakwood Blue (G. F. Wilson, Esq.).—A seedling from Scott Wilson, which has been flowering in the open border since the end of January, and was lifted the previous day for exhibition. The flowers are 1½ inch across, deep blue, with a yellow centre; one of the finest of the blue Primroses yet obtained.

Polyanthus Terra Cotta (Mr. R. Dean).—A distinct variety of Primrose, the flowers of a peculiar shade well expressed by the name.

Pyzidantha barbatula (Messrs. Paul & Son).—A dwarf tufted plant like one of the small Saxifrages, with minute white starry flowers scattered over the plant at the points of the growth.

THE LECTURE.

At 3 P.M. a general meeting of the Society was held in the Drill Hall, D. Morris, Esq., in the chair, and there was a remarkably good attendance of Fellows and visitors. Several new Fellows having been duly proposed and elected, the Chairman introduced Mr. W. Ingram of Belvoir Castle Gardens, as a well-known authority on the subject which he had undertaken to discourse upon, namely, "Spring Flower Gardening." The lecturer then proceeded to deal with his subject in a thoroughly practical and interesting manner. He divided spring flowering plants into two groups—those that flower in early spring, viz., from February through March; and late spring, from March through April to May. The latter included the great bulk of plants which gave attraction to the flower garden at that period of the year. The names, characters and requirements of the chief species were enumerated, and much special information derived from a long experience was conveyed to the audience. The Rock Garden was next described, the best mode of construction, arrangement and planting, a free, natural style being advocated in opposition to the formal designs too frequently seen. The shrubs adapted for shelter as well as for adornment of the rockery were also referred to at some length, and Mr. Ingram concluded his able lecture amidst hearty applause. These afternoon lectures are evidently much appreciated, though the hall itself is not well adapted for the purpose.

DAFFODIL EXHIBITION AND CONFERENCE.

PARTICULARS of the Exhibition of Daffodils to be held at Chiswick, April 15th to 18th next, are issued in a schedule and programme, of which the following is the substance:—

Schedule.—For the better examination and comparison of the flowers it is particularly requested that exhibitors will divide their collections into the following classes:—Classes 1, *Corbularia*; 2, *Ajax* (yellows only); 3, *Ajax* (bicolors only); 4, *Ajax* (white or pale sulphur—e.g., *albicans*, *cernuus*, *moschatus*, *pallidus præcox*, *tortuosus*, &c.); 5, *Incomparabilis*, *Barri*, and *Leedsii*; 6, *Humei*, *Backhousei*, *Nelsoni*, *montanus*, *Macleai*, *Sabini*, *Bernardi*, and *tridymus*; 7, *Triandrus*; 8, *Burbidgei*, *poeticus*, *odorus*, *juncifolius*, and *Jonquilla*; 9, *Gracilis*, *intermedius*, *polyanthus*, and double *polyanthus*; 10, Double and semi-double Daffodils of all kinds—e.g., *Ajax*, *incomparabilis*, *odorus*, *poeticus*, *Jonquilla*, &c., except *polyanthus*; 11, New or unnamed seedlings of the *Ajax* classes; 12, New or unnamed seedlings of any other class than *Ajax*. No doubles or semi-doubles may be shown in classes 1 to 8 inclusive. The flowers may be shown set up in bunches or separate, according to the fancy of the exhibitor, and with or without foliage. No limit is placed on the number of flowers of a sort, but it is most desirable that, however many of a sort be shown by any one exhibitor, that they should be all staged side by side. Thus, if a dozen bunches of *Empress* be shown by one exhibitor, they should all stand together, and not be mingled about indiscriminately with *Horsfieldi*, *grandis*, &c., and so on. In the case of any new or little known forms the exhibitor is requested to state, in writing attached to the flowers, the points in and for which he considers them superior to or more desirable than older or more generally known forms.

Prizes.—In addition to any awards which the Council of the Society may themselves see fit to make at the time to any exhibitors in the foregoing classes, the following prizes have been placed at their disposal:—

Open to amateurs only.—Classes 13, A silver challenge cup, presented to the Society by the Rev. W. Wilks, Sec. R.H.S., for the best collection of Daffodils, grown by exhibitor in the open (*Polyanthus* excluded); not more than five blooms of a sort. If won by the same exhibitor two years in succession to become the property of the winner. 14, A large silver medal, presented by Messrs. Barr & Son, for the best and most distinct fifty varieties of Daffodils, three varieties of each, to include representatives from the *Trumpet*, *incomparabilis*, *Barri*, *Leedsii*, *Backhousei*, *Nelsoni*, *Burbidgei*, *poeticus*, &c., sections. No *Polyanthus Narcissi*. 15, A small silver medal, presented by Messrs. Barr & Son, for the best and most distinct twenty-five varieties of Daffodils, three flowers of each. The three great groups, *Magni-coronata*, *Medii-coronata*, and *Parvi-coronata* must be represented. No *Polyanthus Narcissi*.

Open to all Comers.—16, A large silver medal, presented by Messrs. Barr & Son, for the largest, finest, most varied, and distinct collection of Daffodils irrespective of the number of flowers. No *Polyanthus Narcissi*.

Arrangements for the Conference.—Tuesday, April 15th.—The Judges and Committees of Selection will be engaged in examining the flowers and drawing up their reports. Fellows will be admitted to the gardens at 1 P.M., and the public at 2 P.M. Her Royal Highness the Princess Mary, Duchess of Teck, has kindly consented to open the Exhibition at 3 P.M.

Wednesday, April 16th.—Admission to the Gardens at eleven. The

Conference will be opened at two o'clock by Professor Michael Foster, Sec. R.S., President of the Conference, who will deliver an opening address. Mr. C. R. Scrase-Dickins, Secretary of Narcissus Committee of the R.H.S., will give a short *résumé* of the work done by the Committee since its appointment in 1886, and will present the report of the Committee as to the exhibits and the awards of the Judges. The following papers will then be read, and discussion invited:—"Historical Account of Cultivated Narcissi," by Mr. F. W. Burbidge, M.A., F.L.S. Mr. T. A. Dorrien-Smith has been asked to read a paper on "Daffodils in the Scilly Islands." "The Poeticus Group," by the Rev. G. H. Engleheart, M.A.

Thursday, April 17th.—Admission to the gardens at eleven. The Conference will be resumed at 2 P.M., Mr. J. G. Baker, F.R.S., in the chair. Papers to be read:—"On the Natural History and Cultivation of the Trumpet Daffodil and its Hybrids," by the Rev. C. Wolley-Dod, M.A. Herr Krelage has been asked to read a paper on "*Polyanthus Narcissi*." "On Irish Varieties of Daffodils, with Special Reference to the White Forms," by Mr. John T. Bennett-Poe; "Notes on Seedlings and Seedling Raising," by the Rev. G. H. Engleheart, M.A.; "Daffodils for the London Market," by Mr. James Walker.

Friday, April 18th.—Admission to the gardens at eleven. The Exhibition will close at 4 P.M.

The following ladies and gentlemen have been requested to act as Judges of the various classes:—Mr. T. A. Dorrien-Smith, Herr Krelage, Mr. James Walker, Mr. Walter Ware, Mr. F. Moore, Miss Jekyll, Rev. C. Wolley-Dod, Rev. G. H. Engleheart, Mr. F. W. Burbidge, Lady Henry Grosvenor, Miss H. M. White, Mr. Bennett-Poe, Rev. G. P. Haydon, Sir John Llewelyn, Bart., Mr. C. W. Cowan, Mr. H. J. Elwes, Herr S. A. de Graaff, Mr. J. G. Baker, Mr. W. Alfred Dickson, &c.

Intending exhibitors are requested to communicate with Mr. Barron, Superintendent, R.H.S. Gardens, Chiswick, on or before Friday, April 11th, stating the classes in which they propose exhibiting, and giving an approximate idea of the amount of space they will require. Any other flowers exhibited during this Conference must be kept quite separate from the Daffodils.

CULTIVATION AND SELECTION OF POPULAR ORCHIDS.

BY MR. ALEXANDER WRIGHT.

[Prize Essay, Chiswick Gardeners' Mutual Improvement Association.]

(Concluded from page 285.)

POTTING.—The material used for potting purposes is in itself so simple that it loses much of the mysterious properties attached to various compounds often recommended for potting different stove and greenhouse plants. For the epiphytal Orchids, good fibry peat, sphagnum moss, that grown under trees to be used in preference to that found growing in water; the former being shorter in its growth, and more compact, a neater finish can be given to the plants when potted, and I find that it grows better and lasts longer than that found growing in water. Charcoal may be used with advantage, but if not readily obtained broken pots may be used instead. In crocking the pots keep the potsherds on edge, rather than lay them flat, as it will allow a stick to get a firmer hold in using one to tie the plant or flower spike to. In using the peat knock all the dust out of it on the bench before using, using only the rough pieces, with about equal parts of sphagnum, with the addition of a few pieces of charcoal or potsherds, which help to keep the material open. Finish the pots neatly by using the compact growing pieces of sphagnum, placing them so that they will grow on the surface.

In potting *Odontoglossums*, I do not recommend the plan of keeping the plants raised above the top of the pot as is often seen. If the base of pseudo-bulbs is just elevated above the edge of the pot, that will be sufficient. Nor should the pot be filled to the rim with the potting material, rather allow about half an inch, so that should the plant get dry at any time it can be watered with the watering can, and without having recourse to dipping, a plan that requires much time to carry it out.

There are plants on the other hand that are better raised, such as those that emit roots freely, and prefer to grow out of the material rather than in it. Examples of this kind will be found amongst the *Oncidiums*, *Vandas*, *Aerides*, &c. The *Cypripediums* are often raised unnecessarily high in their pots. In potting them there ought to be room left for watering. Most of the *Cypripediums* will be benefited by the addition of a few small pieces of turfy loam to the peat and sphagnum in potting, and for some of them, such as *niveum*, *concolor*, &c., the addition of small pieces of limestone will make a great difference to the well-being of the plants.

The terrestrial Orchids will require more substantial material to grow in. *Calanthe Veitchii*, *Phajus grandifolius*, *Peristeria elata*, *Anguloas*, &c., can best be grown with good loam, manure, and leaf soil, to which some bonemeal may be added. Nor will the plants be required to be raised in the pots, like the epiphytal group, but enough room

should be left for watering. *Coelogync cristata* and *Lycaste Skinneri* are improved in their growth by leaf soil being added to the peat and sphagnum, and the *Pleiones* are the better for leaf soil and bonemeal.

Let me here strongly recommend that all Orchids should be repotted every year at least, and all decaying material, or any not having roots in it removed, and replaced with fresh material. This will be found to keep the plants in better health than where the system of top-dressing is resorted to and the plants allowed to go on for perhaps two or three years without being potted. The consequence of such treatment is that when the plants are turned out of their pots, the roots are found in a very bad state. The plants thus receive a check from which recovery is often a slow business.

There are a few plants that may be allowed to go for two or three years without repotting, and they are those the roots of which adhere firmly to the sides of the pots or baskets, rather than to the material in which they are potted. With all the terrestrial and with most of the epiphytal Orchids, this year overhauling will be found to do them good. The system of top-dressing should be guarded against, and never carried to excess, as is often done.

The best time for potting the different species and varieties is a most essential point in the successful culture of Orchids, and for which no "hard and fast" rules can be laid down, but it may be taken as a general rule that the best time is when the plants are starting into growth.

MANURES.—The question of applying artificial manures to Orchids is often raised. Some good growers recommend it, others equally experienced condemn it. But I think there are but few growers but will admit that some of the species are greatly benefited by the judicious use of manures, such as the application of bones, in the form of bone meal, for many of the terrestrial Orchids. One large grower I know speaks very highly of horse droppings, such as would be prepared for a Mushroom bed, being added to the potting material for *Lycastes*, and watering *Odontoglossums* with weak manure water, made by steeping the droppings in water some time before using. He says the different appearance of the foliage after the use of the manure water is marvellous, and he is gradually giving such treatment to the whole of his *Odontoglossums*. I do not recommend any radical change in the culture of Orchids where the plants are doing well, but experiments carefully carried out often lead to a more successful mode of treatment. Do not for a moment let us suppose that we have yet reached the limit of successful culture in Orchids, great as has been the stride made in that direction during the last few years.

WATERING.—When to water and when to withhold water is another most important question. As a general rule plants require most water during their growing period, but even then great care must be taken not to overwater. The sphagnum growing on the surface of the pots will help as a guide to watering. To keep the sphagnum green and growing on all plants during their growing season, and on cool Orchids all the year round, will be the aim of most Orchid growers. Allowing to become partially dry before watering will in most cases ensure enough water to the plants. The plants under this treatment will produce good growths and flower spikes in abundance. Guard against keeping the sphagnum always soaked so as to rot it; the growth made under such conditions is not the kind to flower freely.

SYRINGING will be necessary during hot, dry weather; it helps the plants as well as keeps down insect pests. As *Dendrobiums*, *Cattleyas*, &c., mature their growths, remove them to a cooler house where they can be more fully exposed to the light. But where this cannot be done, move them to the cool end of the house, and keep the syringe from them. I am no advocate of the dry system that is still too common amongst Orchid growers, of keeping many of their plants quite dry after having matured their growths.

After syringing during the afternoon shut the house up close for about an hour afterwards. This greatly helps the plants, and is a system I follow with good results. Watering during the winter months is best carried out in the morning, and during the summer it will be necessary to look over the plants twice a day. Although I mention those times as being generally the most convenient, never let a plant suffer by want of water, however often and at whatever time it may require it. The true plant lover (and he is generally the successful plant grower) watches over his plants with care and attention, knowing the watchful eye to be essential to success. No other person can see so much beauty in a plant or flower as the painstaking and watchful cultivator who has followed the plant through all the various stages of its growth—it may be from the small seed. And is it to be wondered at if he sees beauty where others fail to see anything? This, I think, accounts

for gardeners often estimating their own products as superior to others, for they believe them to be so, and the conviction is the result of the intense interest that careful cultivation encourages.

SHADING.—It will be necessary to protect the plants from bright sunshine, and for that purpose there is nothing better than roller blinds. The material known as hexagon netting is very suitable, admitting plenty of light, yet breaking up the sun's rays, so that no burning or scalding of the plants takes place under it. The advantage of a roller blind over permanent shading is considerable, and the latter should never be adopted where the roller blinds can be had. In dull weather the blinds should not be used, and in fine weather they ought to be rolled up early in the afternoon to allow as much light as possible to reach the plants without causing scorching. With plenty of light the plants make sturdy well-ripened growths, one of the necessary conditions to ensure free flowering. During the autumn and winter months it will not be necessary to use the shading, as all the light we obtain then will be beneficial to the plants.

INSECTS.—Cleanliness is next to godliness; and as regards plants—whether it be Orchids or any other plant—cleanliness is of the first importance. The greatest of Orchid pests, and the most difficult to eradicate, is yellow thrips. For the destruction of this insect there is nothing better I know of than dipping the plants in tobacco water, to which some softsoap has been added. After dipping lay the plants on their side to drain, afterwards syringe with clean water, and where they are troublesome repeat the operation at intervals of about a fortnight until they are got rid of. For scale there is nothing better than sponging the plants carefully with soap water, or some of the many insecticides recommended for this purpose. For green fly we have found the carbon vapour cones very effectual. It is well known that tobacco smoke causes the leaves of the *Odontoglossums* to turn yellow and drop, so that where they are grown it is better not to use it as an insecticide. If the plants are looked over periodically and cleansed insects on Orchids are never troublesome, and, as I have already said, the plants as well as the houses ought to be kept scrupulously clean at all times.

DISEASES.—What is known as "spot" will be found one of the most troublesome to keep clear of. There seems to be great difference of opinion as to the cause of it. I am inclined to attribute it to cold, the plants receiving a chill at some time or other. One thing is certain, if any of the hot section should be kept too long in the cool house spot very soon appears on the plants, and is a sure sign the plant is suffering from cold.

SEEDLING ORCHIDS.—The raising of seedlings of any plant is interesting work, but with Orchids it is more so than with most plants. Some of the causes for this may be that the so-called species as laid down by botanists do not appear very definite, often we cannot tell where one species leaves off and another begins, so that we may safely conclude there is a wide field open to the hybridist. As a general rule, we find that few species of other flowering plants will cross with one another, but with Orchids I do not think this difficulty exists to near the same extent. My experiments in this direction have not extended over many years yet, but the results so far are encouraging. I have found that not only species will cross with one another, and that even genera do not stop the pleasure to be derived from this interesting work. From the experiments I have already carried out I am inclined to think that most of the Orchids will cross with one another, as we find suitable seed-bearing plants. I am further strengthened in this belief by the construction of Orchid flowers resembling one another to a greater extent than is to be found amongst other flowering plants. If we take two of the widest apart genera, amongst other Orchids say *Cypripedium* and *Odontoglossum*, we find that cross-fertilisation will be a difficult matter, but, I think, will yet be accomplished. I have often tried to get a cross between the two, but until this season I have never noticed that the pollen mass of the one has had any effect on the other; but this season I have succeeded this far, that the pollen from *Cypripedium* has affected the stigma of *Odontoglossum*, so as to close on the pollen and cause the ovary to swell. In the *Cypripediums* the pollen is broken up into single grains, while in *Odontoglossum* the pollen is in a mass and not granular. This would make a cross between the two genera the more remarkable. I am aware that the swelling of the ovary does sometimes take place without any seed being developed, but on the other hand the affinity between the two genera must be very close for the pollen of one to take any effect on the stigma of the other, for I take it there must be some effect before the ovary begins to swell, beginning when the stigmatic disc closes on the pollen masses.

That is one of the interesting parts connected with crossing Orchids; another is the raising of the seedlings and the careful watching they

require through the number of years until they flower. Then the real interest is at its maximum, and we reap the fruits of our labour. Let me recommend all who have a few Orchids to try what can be done in hybridising, although it may take a long while to see the result of our experiments. Remember "time is always on the wing," and that they are "growing while we are sleeping."

The cultivation of the hot section differs but little from the cool section, and where they can be cultivated as well as the cool section, it adds considerably to the richness of the collection, both in colour and variation in the flowers. To see the plants in perfection when in flower, they ought to be removed to a house that can be kept drier, which enables the flowers to last longer in perfection, and if arranged with light elegant Palms and Ferns, their beauty is considerably enhanced and their diversity of colour and form may be admired at leisure.

CHRYSANTHEMUMS—NEW VARIETIES.

[Read at Sheffield by Mr. W. Housley.]

THIS subject to most amateurs is a perplexing one. When I say perplexing I do not mean that it is so exactly in the cultivation of the plants, but in the selection of varieties that will be the most likely to give him satisfaction, either as show flowers, fit for the best row on his board at an exhibition, or as decorative plants bearing a number of fairly good blooms.

I seldom procure new varieties the first season they are offered for commerce, for this reason—nearly all such varieties are limited in numbers, and consequently in cuttings, and therefore are placed in heat to force them to produce a good supply for the market. This is the cause of weak, elongated cuttings, which will certainly not produce exhibition blooms or anything approaching them.

Take for instance Mrs. Alpheus Hardy, which, according to the flattering accounts given in the horticultural papers, was the best Japanese variety which had made its *débüt* for some time. This variety was largely sought for, and the result, at least in the north, has not been very satisfactory, as only a few very medium blooms have been seen. The cost of this variety, which was of American origin, amounted to something like £300, and I think will most likely turn out disappointing to English growers. The hair-like growths (which is stated to be its great feature) on the surface of the petals is by no means new. Mr. Tunnington of Liverpool, one of the most experienced growers in England, assures me he has had the same thing occur with such varieties as Chang, Hero of Stoke Newington, and Princess Teck, under good cultivation, although perhaps not so much so as in this variety.

I believe never before in the history of Chrysanthemum culture were new varieties so numerous or so eulogistically described as in the present season. Years ago we complained of the French raisers each season sending us such a large number, all with very high-flown descriptions, but very very few of which turned out equal to existing varieties; but now cousin Jonathan, who is nothing if he does not "lick creation," has apparently taken his cue from the French, and is endeavouring to out-Herod Herod. Every catalogue teems with new American varieties, the descriptions of which are enough to drive a 'mum enthusiast crazy, especially if his pocket is not too well lined. Mr. Owen catalogues no fewer than sixty new American varieties for 1890, and almost as many for 1889. Messrs. Cannell, Davis, Laing, Boyce, and Morton have long lists, differing in many varieties. Mr. Holmes has another list entirely to himself, which he calls the "Messina collection," being a collection sent over to a New York Lady by a young Japanese gentleman, and out of which came Mrs. A. Hardy, of which I have previously spoken. This collection comprises eleven varieties—Bella Hickey, Emma Ricker, Kioto, Kabayama, Lillian B. Bird, Medusa, Mrs. Fottler, Messina, W. H. Lincoln, Nippon, and Mrs. A. Hardy. The best of these I think will be Kioto, Mrs. Fottler, and Mr. W. H. Lincoln; they are certainly the most likely candidates for public favour. The demand for Mrs. A. Hardy this year is, I believe, very small, and is attributable to one of two causes. First, the American firm who introduced it appear to have then scoured the country in search of buyers, and thus distributed it very extensively; and secondly, there appears to be an almost unanimous opinion amongst exhibitors, and those who have either themselves flowered it or seen it flowered, that it will not make a successful exhibition variety.

I am not favourably impressed with the American descriptions of a flower, as they either do not know what the English standard of a good bloom is, or they are exaggerated. One of the largest of northern growers grew eighteen of the newest American varieties last year, all with a glowing description, but only to meet with the keenest disappointment, and to consign sixteen to the rubbish heap. Of those new varieties which have upheld their reputation and which have produced

first class blooms, Sunflower is a splendid grower. The same can be said of Etoile de Lyon, although a little coarser than that previously named. Florence Percy, a good bloom, though small if produced from the crown bud, is a fine flower. The same may be said of Gladiator, Marsa, Mad. Louise Leroy, Condor, with very broad florets, George Daniels, a light pink, remarkable for its width of petal. Mad. A. Carnegie, scarlet crimson, is sure to come to the front, as is also W. W. Coles, a bright red. These two last named are sure to take a foremost place.

I may safely say that the most favourite Japanese of the year will be W. W. Coles. It is now greatly in demand, and there is likely to be some difficulty in obtaining it, as I understand all the leading raisers have considerably more orders on their books than they have plants to meet them with. This variety was exceedingly well flowered by Mr. Pearson at the Chilwell Nurseries, and he has a high opinion of it. Next in order comes Volunteer (syn. Mrs. Irving Clarke) and Beauty of Castlewood. The last named is very scarce; the first named is a fair bloomer, and will no doubt become a great favourite and useful variety; its build and style (that of Belle Paule) is of a most pleasing and effective character. L. Canning will also become a very popular variety, for its close compact habit of growth, in which respect I think it surpasses Avalanche; it is a pure white and said to be a deep, well built flower if well grown.

A few new varieties, which have been discarded by a well known northern grower, are Moonlight, Mr. and Mrs. H. Cannell, Ceres and Pelican, none of which will prove satisfactory so far north as Sheffield unless we have a most exceptionally fine hot summer. These require more heat to properly develop and open the flowers successfully than any others, although at the same time most Japs delight in a gentle heat, and expand more freely if so treated.

Of the new incurred varieties only two call for any special comment—viz., Mr. T. Coleman, sent out by Mr. Owen of Maidenhead, and John Lambert, raised by Mr. J. Lambert of Shrewsbury. The first named is a sport from Princess of Wales, and has received six first class certificates. It resembles its parent in every respect except colour, the lower part of the flower being a bright golden bronze, shaded rose, the upper portion often bright yellow, inside the petals of a pale yellow. This is one of the most valuable acquisitions ever obtained, and should certainly become a favourite.

John Lambert is a magnificent flower both in build and solidity. It is a sport from Lord Alcester, but superior in form. It was also exhibited at Sheffield, and, although not obtaining a certificate, was not the less deserving of one. The fact that the flowers had been shown at a previous exhibition had certainly somewhat militated against what must have been an exceptionally good trio of blooms when cut from the plants.

Mr. Molyneux has rather decried this variety in some of the horticultural journals, giving it as his decided opinion that it will not be found equally valuable as an exhibition variety with the two new ones sent out last year—viz., Violet Tomlin and Miss Haggas; but even Mr. Molyneux is not infallible, and I think too much stress should not be laid on his opinions on this point. John Lambert sported with the raiser (Mr. Lambert) of Shrewsbury in 1886 or 1887, since which time it has continually been shown by Mr. Lambert on his incurved stands, and has no doubt contributed largely to his success. No Golden Queen of England or Emily Dale can approach it for build or colour, and it is a much stronger grower than its parent.

Ada Spalding, one of the new American varieties, has been grown by Mr. Owen, who has successfully flowered it, and who takes it to be an excellent variety. It is a splendid grower, making large, stout, fine looking foliage, and as flowered last autumn was quite satisfactory in every respect, and should be seen in a conspicuous position on most winning boards this coming autumn. John Doughty, a sport from Queen of England, colour a rosy fawn, a decided improvement on the Bronze Queen, is also good. Violet Tomlin, a bright violet purple, a tall grower, good foliage, and a good solid flower, is one of the newest and best as a show variety. Miss Haggas, a bright soft yellow, is also a tall grower, and is equally good with the last named. They are, however, both rather taller than the majority of amateurs can conveniently house.

Of new Anemone flowered varieties which will no doubt become acquisitions may be named Mrs. Judge Benedict, Mrs. Chas. Pratt, Mr. E. C. Jukes, and Gladys Spaulding. Of the early or summer flowering varieties Golden Shah, an English raised seedling, is likely to become popular, from its dwarf compact habit, good foliage, bright yellow flowers, and earliness.

HARDY FLOWERS AT KEW.

ALL lovers of hardy flowers will find themselves amply repaid for a visit to Kew at the present time. The gardens always present something interesting to the visitor, and just now the chief attractions are the wealth of spring flowers which everywhere meet the eye.

The method adopted of planting these on the grass is a great success. The wild garden on the mound near the Cumberland Gate is worth a journey to see, the thousands of Narcissi having a most imposing effect, while the Hyacinths present quite a blaze of colour which is softened down by their carpet of green. In no position does the Hyacinth display itself to so much advantage as when planted on the grass, as here it loses the stiffness and formality which characterise it in beds and borders. All bulbs which are of no further use for pot culture

might be utilised for this purpose, and the result would prove most satisfactory.

The rock garden, though not yet at its best, contains many gems, which make it well worthy of more than a passing glance. Some of the most noteworthy of these are *Saxifragas* (*Megasea*) *speciosa* and *Stracheyi*, *Erica carnea*, *Scillas*, *Muscari*, *Erythroniums* and *Chionodoxas*. A small patch of the beautiful blue *Anemone blanda* nestling at the foot of a large boulder is particularly pretty, while a tuft of the yellow *Draba aizoon*, perched on a huge piece of rock, looks quite at home and is flowering profusely. The lovely *Narcissus cyclamineus*, with small yellow flowers, is also particularly fine.

The alpine house presents a gay display, and shows what can be done with even the commonest spring flowers when properly treated. This house is unheated, and with the exception of a few *Primula obconica* all the plants have been grown in cold frames, yet we unhesitatingly say that no house in the gardens—Orchid houses not excepted—can approach it in its wealth of beautiful flowers, which are not the less attractive and interesting because many of them are comparatively common and easily grown. Many amateurs have a difficulty in keeping their greenhouses gay during the early spring months, being unable from motives of economy to provide sufficient fire heat to keep ordinary greenhouse plants through the winter. To all such we would recommend a visit to the alpine house at Kew, where they will doubtless learn something which will be useful to them. Besides the finer *Narcissi* and *Bulbocodiums* there are *Hepaticas*, *Millas*, *Anemones*, *Sisyrinchiums*, *Corydalis*, *Scillas*, and a host of other fine spring plants. A group of the dwarf snowy white *Primula pubescens alba*, more commonly met with as *P. nivea*, is charming; *Collinsia verna* is also very fine, while *Cyclamens repandum*, *hederifolium*, and *Atkinsi* are flowering freely, and look exceedingly pretty.—R. G. K.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY, EDINBURGH.

THE spring Exhibition was held in the spacious Waverley Market on the 2nd and 3rd of the present month, when a fairly good show of plants and cut flowers was staged on the various tables and on the floor of the building. Fruit and vegetables were shown in very small quantity. Of the former very fine Noble Strawberries secured the first prize for Mr. McIndoe, Hutton Hall, Guisborough, the same exhibitor being first for two bunches of black Grapes, Mr. Potter, Seacliffe, North Berwick, occupying the same position for collections of dessert and kitchen Apples, both in very fresh condition. Of vegetables there were good examples of French Beans, Broccoli, young Potatoes, Leeks, saladings, and collections, the latter being hardly so good as they generally are at Edinburgh.

Of plants, very noteworthy were the beautiful examples of *Azaleas* shown by Mr. Paterson, Millbank, who was easily first in the several classes in which he competed. The six stove and greenhouse plants and the Cape Heaths staged by the same exhibitor were also good. Orchids were not numerous, Mr. Grossart, Canaan Lane, alone staging six plants, *Cymbidium Lowianum* being prominent among these. Mr. McIntyre, The Glen, won with three, a fine example of *Cymbidium eburneum* being the best of them; Mr. Cunor being second, and Mr. Patterson third. A *Dendrobium nobile* secured for Mr. McIntyre the first prize for one Orchid. Mr. Napier, Rockville, Murrayfield, secured the first prize for four exotic Ferns and for three *Adiantums*, with fine fresh specimens. Mr. Bennett, Corstorphine, won with four foliage plants, the best examples of three *Dracenas* coming from Mr. Grossart. Some not large but fresh Rose plants were set up by Mr. J. Patterson. The first prize Chinese *Primulas* were large and well flowered; these were from Mr. Bald, Oswald Road. Mr. Rae, Sunlows, Kelso, was first for six *Cinerarias*, with good plants of a fine strain. Lily of the Valley, *Primulas*, Alpine plants, *Mignonette*, and some other classes were rather deficient in quality. *Hyacinths* were also rather weak, though some good spikes were noteworthy in some of the collections. Mr. D. McBean, Johnstone, secured the first place respectively for twelve and for eight plants, with generally good and massive spikes. Mr. Brydon, Tweedbank, Innerleithen, in the class for amateurs (not gardeners), had also good examples, with which he easily carried off the first prize. The other bulbous plants call for no special comment. The table of plants arranged for effect brought out only one exhibitor, Mr. Grossart, and to him the first prize was awarded. In the open class for a table of hardy flowers Messrs. Munro & Ferguson were first, being the only exhibitors. In the cut flower classes were some good Roses, Mr. N. R. Henderson, Clermiston, being first for twenty-four blooms in eight varieties. The best twelve blooms of *Gloire de Dijon* came from Mr. Chalmers, Davidson Mains; and the best twelve of *Maréchal Niel* from Mr. T. Fender, Crieff. Mr. McIntyre, The Glen, was first respectively for twelve blooms of stove and greenhouse plants and for twelve Orchids.

In the section confined to nurserymen the chief interest centred in two groups of plants arranged on the floor of the building. The one was oval-shaped in outline, the chief features being some good *Azaleas*, not too profusely covered with flowers, and some good Palms standing boldly out from the small Ferns and other plants, which were freely used to hide the pots. This group was from Messrs. R. B. Laird and Sons, West Coates, and to it the first prize was awarded. The other had the oval broken by a bulge in the centre of the two longer sides, a feature which had no beneficial effect. Palms, *Lilium Harrisii*, *Dracenas*, *Orotans*, and various fine foliage plants were skilfully

arranged, though perhaps in too great numbers, the undergrowth being much of the same character as in that above described. Messrs. Ireland and Thomson, Craigleith, contributed this group, and secured the second prize. The same exhibitors were the sole exhibitors in various other classes.

Among the miscellaneous exhibits not for competition, great attention was attracted to a group of *Primula Sieboldi* from Messrs. Ryder and Son, Sale. These were set up among Maidenhair Ferns in very neat form. Messrs. Barr & Son, Covent Garden, had a small collection of cut Daffodils which were of much interest as containing some of the newer good forms, such as Mrs. Gammel, Countess of Annesley, &c. Messrs. T. Methven & Sons, Princess Street, set up a group of ordinary decorative plants, one of the prettiest in the hall. The weather was remarkably fine on both days, too fine, indeed, for the benefit of the Society, if one might judge from the attendance at various times, which was very small, the genial atmosphere out of doors being apparently more attractive than the glow of beauty within.

HARDY FRUIT GARDEN.

FIGS.—Those who neglected to protect these in any way will perhaps regret not having attended to this important matter. The very severe frosts experienced during the early part of March appear to have completely killed the embryo fruit at the points of all unprotected shoots, and it is doubtful if even those lightly protected were proof against such a low temperature as 20° below freezing point. They would have withstood an equally severe frost earlier in the winter, but Figs, in common with all other hardy fruits, were moving much earlier than usual. In all probability there will be a scarcity of those luscious fruits next August and September.

PRUNING FIGS.—All mats, Fir branches, or other protecting material of a heavy nature ought now to be cleared from the trees, but it is advisable to delay what pruning may be considered necessary till such times as it will be seen which branches or shoots are fruitful or not, this being the most likely method of securing a fairly good crop. Late pruning is always perfectly safe, Figs apparently possessing any amount of vital power. Trees with their branches growing unrestricted from the walls, these frequently being the most productive, ought merely to be lightly thinned out, all suckers or gross shoots springing from the base of the trees being also removed. Those kept neatly trained to walls to have some of the longest and most naked branches cut well back to the main stems; this gives the more serviceable wood more space, and also causes the formation of younger shoots nearer the base of the tree, or where they are most needed. It is almost needless to point out that the fruits are borne at the points of well matured young shoots, and the latter ought not therefore to be shortened, but must be laid in to their full length. No notice should be taken of the destruction by frost of partially developed fruit, as these never swell and ripen. At present this season's crop, or what should have been such, is in a bud state, but they will develop rapidly and in advance of the foliage. Be very sparing of the knife in the case of vigorous young trees, as the more these are pruned back the more luxuriant, and therefore unfruitful, they become.

PLANTING FIGS.—In most cases nurserymen keep their stock of young trees in pots, and they can consequently be ordered and planted any time during April or May, the former month from choice. The most generally productive varieties are the Brown Turkey, White Marseilles, and Brown Ischia, the first named being the most commonly grown. The Brunswick is quite as hardy as either of the foregoing, and the fruits are very large and good in quality, but as a rule are very thinly produced. A strong sappy growth being neither hardy nor fruitful, it behoves those who are anxious to grow Figs well to plant them in a very sunny position, and in rather poor soil. The best places inside garden walls are the corners formed by the junction of a wall facing south and another facing to the west, than which no hotter position can be found. Figs also succeed admirably against high south walls, the sunny ends of living houses, stables, and outbuildings. On the south coast they do well as standards, and are particularly "at home" against the chalky or other cliffs to be found on the Kentish and other adjoining coasts. Substitute rough drainage for any clayey subsoil there may be in the spots chosen, and plant principally in rather poor fresh loam, to which chalk or mortar rubbish has been most freely added. Make this nearly as hard as the road, and there will then be less likelihood of rank top growth resulting. A roadway or gravel path near to a vigorous Fig tree soon corrects a non-fruitful habit.

FORMING NEW STRAWBERRY BEDS.—The present time is well suited to the formation of fresh Strawberry plantations, especially in cases where they were not established early enough in August to do any good. If kept from fruiting, for the smallest plants will attempt it, all will grow to a large size during the summer, and yield extra fine

early crops of fruit. In the southern districts it is sometimes advisable to delay planting on warm borders till the early Potatoes are cleared off, but in the open quarters the Strawberries being planted now, the spaces between the rows can be cropped with either spring or autumn sown Onions, Lettuces, Spinach, Turnips, or other crops that will not unduly shade them. All delight in well-manured deeply dug ground, but this must be made quite firm, otherwise there will be a plentiful crop of leaves and little or no fruit. The rows of the stronger growers, of which Sir J. Paxton is a good type, ought on all good soils to be not less than 30 inches apart, a space of 18 inches dividing them in the rows. The rows of the less robust varieties, including British Queen and the compact Laxton's Noble, may be 2 feet apart.

TREATMENT OF ESTABLISHED STRAWBERRY BEDS.—These ought not to have the ground between the rows either dug or forked over now, as this destroys many surface roots, also loosens the soil more than is good for the plants. What is needed is sturdy foliage and strong trusses of flowers thrown well above it. They must not, on the other hand, be unduly starved, or the fruit will be small and of inferior flavour. A surfacing of soot, guano, or any other nitrogenous special manure may well be given now or just prior to showery weather. In any case it ought not to be deferred long after the trusses of bloom are showing, and on no account should strong manures touch the foliage or reach the hearts of the plants, or much harm will be done. The principal feeding roots are spread out well clear of the foliage, and long established plants ought especially to have the whole of the spaces between them manured in some way. This to be lightly stirred in and weeds and slugs destroyed by the use of a flat hoe. Nor ought mulching with strawy manure to be long delayed. Applied now, some of its fertilising properties will be washed down to the roots, and in any case it will greatly serve to conserve the moisture in the ground so much needed by Strawberries later on. The market growers make this one good mulching suffice, the rains washing it clean enough for the fruit to rest upon, but private gardeners ought to again lightly mulch with cleaner litter before the crops are far advanced.

FRUIT FORCING.

VINES.—*Early Forced Vines.*—Pot Vines afford creditable crops of early Grapes. Better results, however, are had by planting the Vines in beds or borders. A span or lean-to house answers perfectly, having beds or borders 3 to 4 feet wide, and about 2 feet deep, so as to admit of 6 to 9 inches of drainage, and 15 to 18 inches depth of soil. The Vines being raised from eyes or cut-backs will need to be forwarded in another structure until the Grapes are cut. These being ripe in April will be off by early May. The Vines that have fruited are cleared out, fresh soil is placed in the borders or beds, and the Vines that are to fruit the following year are planted at 27 to 30 inches apart. If they have made considerable progress, but are not root bound, they may be turned out with the ball entire, firming the soil well about them, and supplying water freely. If in small pots they should be disentangled and the roots spread out. Turfy loam with an admixture of about a sixth of old mortar rubbish forms a suitable compost, and a sprinkling of some approved fertiliser. The canes being trained near the glass will make short-jointed wood. Stop the laterals at the first leaf and the sub-laterals at one joint, and to every subsequent joint as made. Almost any amount of vigour can be had by encouraging the laterals, but not allowing them to interfere with the principal. This, however, is not desirable for Vines intended to fruit early, as it is necessary the wood be ripened early, and as much food stored in the wood and buds as practicable. If well done they will make canes like walking sticks, with eyes like nuts, and being as much under control as pot Vines they can be matured early and given a rest, so as to be ready for a start by the early part of November. By this plan the root action is considerably extended, and this admits of any amount of feeding, the crops finishing better than those of pot Vines in pots. Cut-backs are very much the best for planting out in the way described.

Young Vines.—Those planted last spring will now be breaking naturally. When the buds have grown about half an inch a little fire heat will prove beneficial, especially on cold days. Remove all buds except one at each break, retaining the strongest, and crop lightly, but supernumeraries may be weighted with as much fruit as there is prospect of their bringing to maturity.

Grapes Ripening.—After commencing to colour the berries swell considerably. In order to insure a full swelling of the fruit inside borders should have a thorough watering and mulching early on a fine day, ventilating freely to allow excessive moisture to escape. A full crop of early Grapes is a great strain on the energies of the Vines, and through it in early forcing perfection in colour is not always attainable, much may be done by a liberal and constant supply of warm, dry air combined with a moderately low night temperature, but the temperature must be well maintained by day—70° to 75° from fire heat, and 80° to 85° with sun heat. When hard forcing is practised red spider usually makes its appearance, and should be prevented by painting the pipes with a mixture of sulphur and skim milk; care, however, must be taken not to use too much, or it will act injuriously upon the skin of the berries and spoil their appearance. The sulphur vapour is more injurious to the skin of white than black Grapes.

Succession Houses.—Attend to thinning the bunches and berries. Stop and remove laterals, especially where there is not room for extension, as to allow them to grow considerably, so as to necessitate a large reduction of foliage at one time, results in a check which often induces

shanking at a later period. See that the borders have plenty of water, and weakly Vines will be benefited by tepid liquid manure. Vines swelling their fruit should have a moist atmosphere. Damp the paths two or three times a day, and if liquid manure be used at the latest damping it will improve the Vines and act as a check to red spider. An ounce of the ammonia manures to a gallon of water is suitable for damping with.

Late Vines.—Dishud and tie down these as they require it. Close the houses early in the afternoon with sun heat, and maintain plenty of atmospheric moisture by frequently damping available surfaces. They are now making rapid progress and must be given every encouragement.

CUCUMBERS.—Plants that have been bearing through the winter will need to be renovated at the roots, removing with a handfork as much of the exhausted soil as is possible without injury to the fibres, and fill with rich lumpy compost, pressing it down firmly. Stopping, training, and cutting out the old growths must be followed up, and abundant waterings given as necessary. Assist plants in full bearing with copious supplies of tepid liquid manure, and earth the roots occasionally. Damp the floors before 8 A.M. and about 3 P.M., the foliage being syringed lightly on fine afternoons, and keep the evaporation troughs filled with liquid manure or weak guano water. There ought not to be any further delay in having the blinds in readiness, so that they may be employed for an hour or two at mid-day, when the sun is brightest. Shading is most needed after a dull day or a period of dull weather (which tends to make the foliage soft) to prevent flagging. Worms, if troublesome, may be expelled by lime water.

MELONS.—Plants swelling their fruits will require supports. Half-inch deal boards, 6 or 7 inches square, with a hole through each corner, and suspended by four pieces of string or copper wire from the trellis in a slanting direction to prevent water lodging, may be employed for the purpose. Pieces of slate with holes drilled in the corners are preferable to wooden supports, and glass would be still better through not being heated with the sun. Remove all flowers from such plants, also superfluous growths, stopping and tying as necessary. The plants must not suffer through insufficient supplies of water, affording weak liquid manure occasionally. Keep the evaporation troughs charged with liquid manure, and secure a good atmospheric moisture by damping in the morning and early afternoon, syringing the plants lightly about 3 P.M. on bright afternoons. Later plants will be showing fruit, and unless abundant remove the first blossoms, it being important that the female blossoms be nearly of one stage of growth. Maintain a somewhat high temperature and dryer atmosphere during the setting, only affording as much moisture as will prevent flagging. Stop the shoots at one joint beyond the fruit, but employ the knife as little as possible during the setting period.

In pits and frames a good bottom heat must be maintained, observing the conditions previously named during the setting. When the fruits are set they must be raised on a piece of slate. Look out for canker at the collar, placing a little quicklime around the stem as a preventive.

PINES.—Plants started into fruit early in the year are fast approaching the flowering period, and will be benefited by an occasional sprinkling overhead at the time the house is closed, but when in flower they must not be so treated. The foliage being as yet tender, it will be desirable in the case of houses with large panes of glass to afford a slight shading for an hour or two at midday for a few weeks until the foliage becomes inured to the sun's influence. When the flowering is over the fruit will advance rapidly if the roots are in good condition, and plentiful supplies of weak liquid manure will be requisite. Attend to ventilating early in the morning, commencing when the temperature is at 80° and closing at 85° with sun heat. Keep the atmosphere moist when the house is closed, the bottom heat steady at 80° to 90°, the night temperature 70°, and 75° by day artificially. As soon as the suckers appear remove all except one to each plant.

THE BEE-KEEPER.

SEASONABLE NOTES.

PUNIC BEES.

THERE appears to be some misunderstanding regarding what I have said about the hives of these being weak, as I have several inquiries about them on that point. Both of my stocks were simply a handful of bees with their queen last July, having no assistance whatever but feeding, consequently were merely nuclei, and not very strong either when winter set in. Notwithstanding this drawback they are increasing quickly, and work on days and at times when no other bees are abroad, quite confirming what "A Hantsshire Bee-keeper" has said about them; and as the weather is now much warmer, although frosty at night, the bees are gathering as much pollen as they can carry, principally from the Tussilago,

which is very plentiful, and will in a few years be a plague to the husbandman. Honey is also being gathered; the Grey Willows supply it plentifully, and I observe the Punic bees are gathering more in proportion to their strength than other bees are. I hope this will be a sufficient explanation, though I thought the context of my article at page 269 made all clear.

SPREADING BROOD.

Although this subject has been frequently before your readers, one phase of it has not. It will be remembered that when it was first suggested there was not the slightest hint as to caution being exercised. The latest advice I have seen published is as amusing as it is sure to be a failure. Here it is. "As the centre combs are well advanced with brood, and the outside ones will contain eggs and larvæ, lift the centre combs to the outside, and let those outside go to the centre." These may not be the exact words, but are the proper meaning. The idea that the centre combs contain the most advanced brood is absurd. The brood of centre combs have to perform the same evolution as the brood of the outer, and if the beginner will not only think, but examine the combs the queen filled with brood first, about the twenty-eighth day after the bees were hived, or after the bees have commenced breeding briskly, he will find nothing but eggs and grubs in the centre, while the outer combs will contain sealed brood.

FASTENING COMB FOUNDATION.

Having been the first in Great Britain to manufacture comb foundation, following the Germans, I am able to say that there is no plan so effective as the groove, and with genuine wax, properly made sheets, and shallow frames, there is not the slightest necessity for wiring frames. There is no plan for fixing sheets in frames or bars but what I have given a fair trial so far back as twenty-eight years ago. If your readers having the back numbers of the *Cottage Gardener* about 1860, they will find my advice how to fix guide combs by the aid of a heated smooth surface of iron. By the same plan I fastened foundation to bars of supers, and when glass was used strong gum was employed, thereby leaving no mark but the centre rib of foundation on the glass. The Americans are following up this plan, and have brought out an apparatus heated by a lamp to effect the same purpose. If a lamp is to be used the beginner will find it much handier to have it beneath the straight and smooth surfaced metal.

BRACE COMBS.

I have frequently shown how all the extra labour to the bees and excessive propolis about supers may be avoided by using the Stewarton form of crown, with slips or slides of wood, and admitting the bees to the supers from the outer combs only. The Americans, whom our "modern" bee-keepers copy, are troubled about the brace combs and excessive propolis, and devising plans to avoid it. They are in one respect coming to our plans, and one bee-keeper has produced a frame with a double top bar, almost similar to one I used in 1863.

CARBOLIC ACID.

"C. R." asks how carbolic acid should be used in bee-manipulations, as he does not like the smoker. It would be well if every bee-keeper was of the same opinion. Nearly every combustible burned in smokers contains creosote; this when mixed with the smoke colours the honeycomb, and enters the cells containing honey, giving it an unpleasant taste. I was the first to make this simple method of clearing bees from supers or combs public. The late Wm. Raitt of Blairgowrie acknowledged this, and gave me due credit for it. Mr. Cheshire, however, gives Raitt the credit, and others repeat the error. To empty supers of bees, or to drive bees from combs, take medium brown paper, and smear a little on both sides, then quickly but cautiously insert between the combs, and if the day is warm the bees will retreat in a few seconds. The tops of the bars should have a slight touch of the acid; a feather answers the purpose very well, and will be found useful to insert

between the combs to thoroughly cause the bees to retreat. I prefer crude acid, and to prevent robbers a cloth dipped in a weak solution should be at hand to throw over the crown of the hive. The only care needed with carbolic acid is never to use more than will leave the odour, and only on the opposite part you wish the bees to retreat to.

PLAGIARISM.

Plagiarism and appropriating the ideas of others has been rather common of late, and when an editor gets information from one and credits another with it, it cannot be said of him that he is clever. A bee book was published some two years ago, and the reviewer called upon readers to give their opinion, especially that part on removing bees to the Heather. T. Bonner Chambers, Esq., did so, and gave a quotation from the pages of the *Journal of Horticulture* which read not unlike the passage in the book, and asked where the author of the book got his information, but neither the editor nor author replied. There has been appearing in numerous papers and journals articles by "J. Sarginson," which read almost word for word as a portion of the Highland and Agricultural Society's prize essay. The editor of *The Rural World* informs me that it was copied from the *Westmoreland and Cumberland Advertiser*, having been delivered by "J. S." as a lecture. I have as yet been unable to find this individual. Should this meet the eye of any reader of his acquaintance full information of his whereabouts will oblige.—A LANARKSHIRE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Fumigator (W. H.).—We have not seen the article to which you refer, nor the vendor's description of it. Perhaps more particulars will be forwarded in due time. We are glad, however, that you have at last found something that will destroy green fly and thrips.

A Monstrous Phalus Wallichii (T. W. S.).—The flower sent is very interesting as a structural peculiarity. The two petals and one of the sepals have disappeared, and in their place there is an additional lip partially enclosing what would be the ordinary lip. The flower thus has two sepals and two perfect lips but only one column. Were there many flowers on the plant of similar formation?

Apple Golden Ducat (W. W.).—In the "Fruit Manual" the following description is given of the above little known Apple. Fruit, above medium size, 3 inches wide, and 2½ inches high; round, and obtusely angular. Skin, rich yellow, having some pale broken streaks of crimson on the side exposed to the sun, and the whole surface strewed with large russet dots. Eye, open, with divergent segments, like Blenheim Pippin, set in a pretty deep and even basin. Stamens, median; tube, funnel-shaped. Stalk, about 1 inch long, slender, inserted in a wide and deep cavity. Flesh, yellowish, tender, juicy, sweet, and briskly flavoured. Cells, roundish, obovate; abaxile. A dessert or cooking Apple; in use during October and November. A very old Apple, mentioned by Worledge.

The Cucumber Tree (S. B.).—This popular name is applied to the *Averrhoa Bilimbi*, a native of Goa and other parts of the East Indies, and is now cultivated in South America. The tree is only about 8 feet high, and produces a beautiful green, smooth, fleshy fruit, of the size and shape of a small Cucumber. Rheede says that the fruit when ripe is excellent to eat, but when unripe they are preserved with sugar, or vinegar and brine, and although it should be of an agreeable acid

flavour when ripe, yet before they are ripe they are excessively sour. Burman says they contain a grateful acid juice, from which a syrup is made, and a conserve of the flowers, which are esteemed excellent in fevers and bilious disorders. Rumphius seems to think that, even when fully ripened, the fruit can never be eaten raw, but is only used to cook fish, fowl, and other viands, to give them an agreeable acidity, in the same way as we use sorrel and verjuice; they are pickled in brine and eaten as we do olives or capers in conjunction with meats; and preserved in sugar, or with a little saffron, they are recommended to be eaten by those who go sea voyages. The tree is a member of the Oxalis family, and you will find specimens of the fruit in the No. 1 museum at Kew.

Stephanotis floribunda (J. S.).—As you say the plants have had a good season of rest, plunge these in pots in brisk bottom heat. Those planted out may be top-dressed with rich material and have the temperature raised to 65°. If syringed twice daily they will soon start into growth. If there is any trace of mealy bug about the plants syringe them frequently with a weak solution of petroleum and water, 1 oz. to the gallon. When the plants are growing strongly it is difficult to get at this insect, for it establishes itself in the points of the shoots and in the flower trusses. The young plants, wintered in a temperature of 60°, will have new roots and will need larger pots, supplying water with care afterwards. The Stephanotis does well in fibry loam, one-seventh of manure and sand. Plants that are thoroughly root-bound and in large enough pots but lack vigour will bear the reduction of their roots by one-third if done carefully. They quickly establish themselves again after they once commence growing.

Management of Vines (M. B., Ayrshire).—Some Vines show bunches on the laterals when four or five leaves are produced, and bunches ought to be visible on your Vines now, though you give no indication of the length and strength of the growths. If there are clusters of growths from the spurs the weaker should be removed by pulling them off one at a time from each spur daily, till two of the best are left, and when one of these containing a bunch is safely tied to the wire and not likely to break afterwards the duplicate may be removed except there is space of between 18 inches and 2 feet between the spurs along each side of the rods. When bunches form the ends of the laterals producing them should be nipped off at once two, or three leaves beyond, according as there is room for the development of the foliage. This topping should be done when the leaves are the size of a shilling. The process is illustrated in Barron's "Vines and Vine Culture," free by post from this office for 5s. 3d. Aerial roots are the consequence of a moist atmosphere, and sometimes indicate sluggish root action in the soil. One bunch to each lateral is usually sufficient, and superfluous bunches may be removed when those intended to ripen have set the fruit and the berries are ready for thinning.

Treatment of Ferns (G. W.).—Much more peat has been used in the compost for these plants than is really necessary. The cost of good peat after it has been conveyed a long distance by rail is a considerable item annually where plants are grown on a large scale. Many Ferns grow equally well in good loam, rough leaf mould that has laid for twelve months, and sand, with the addition of sandstone broken to pieces or soft bricks. Large plants in many cases do not need potting more often than every second year. When large plants of Davallia Mooreana begin to be bare or crowded with old rhizomes the plants should be broken up and repotted. They lose a few fronds, but soon recover and grow all the better afterwards. Large plants may be potted every second year, cutting away a few of the old rhizomes so as to work a little fresh soil amongst them, and they soon start into growth again and grow vigorously. This Fern does not need deep root room, and large shallow pans for it are infinitely better than pots. It makes a splendid basket Fern where plenty of room can be given it. If pieces are planted in baskets 18 inches over, the rhizomes will soon creep all round it and prove more effective suspended from the roof than a plant in either a pan or pot. Microlepia hirta cristata is a useful decorative Fern, but the stove is too warm for it. In too much heat it soon becomes a prey to scale. The roots of large plants can without injury be reduced, and in a short time they soon grow vigorously again. This Fern usually produces a quantity of small crowns, which at potting time should be taken off and potted up singly. They make handsome plants for decoration in 5 and 6-inch pots, and if well hardened they stand in good condition for a long time. Plants that have been used for this purpose soon start again into growth, when they can be cut into two or three and grown on for the same purpose again. Stove Adiantums will do in the same compost, and strong growers will bear the reduction of their roots without much injury, where this must be done to keep them healthy in the same size pots. The more delicate the variety the greater should be the care in reducing them. All Ferns that it is necessary to grow on should be placed into larger pots without disturbing their roots.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. B.).—The specimen is not a good one for determination, and the flowers were too withered to be examined. It is probably a Boronia or

Tetradlea, and in either case cuttings 2 inches long of the half-ripened wood can be inserted in a compost of sand and peat under a bellglass and placed in a cool frame or greenhouse where they can be shaded from the sun. They will require careful attention to prevent damping, and the bellglass should be removed every morning and wiped inside. The soil also must not be allowed to become dry or they will suffer in that way. All cuttings of this kind need close watching to ensure success. (J. H.).—1, Acacia armata; 2, Acacia pulchella. (A Very Old Subscriber).—A small flowered variety of Odontoglossum pulchellum, similar to that originally named O. Egertonii. (Morpet).—The Daffodil with white sepals and a yellow crown is Narcissus bicolor Horsefieldi, the other is Narcissus princeps.

Renewing Combs (Delta).—To renew combs at this season remove all the outer ones having no eggs nor brood, leaving those with brood untouched until a more convenient season when there are no eggs or brood in them. In place of the removed combs give full frames of foundation; these will be extended and filled with brood much quicker than the old combs, and is a capital method of spreading brood and filling the hives with bees. The manipulation will not in any way deteriorate nor lessen the supply of honey.

COVENT GARDEN MARKET.—APRIL 9TH.

TRADE very dull. A few samples of new Grapes to hand from 5s. to 10s. per lb.—Strawberries in good supply, meeting a heavy sale.

Bedding Plants in variety, in boxes and pots.

CABBAGES.

DIFFICULT indeed is it to say when a crop of Cabbages is most useful to a farmer. Sown now, Sutton's Early Oxheart affords a grand supply of green food by the end of August, when pastures are so often bare, and green fodder of any kind is a boon. Sown in August, and planted out in October, the ordinary Drumhead is in use in June, July, and August, and is then of especial value on East Anglian corn farms, both for ewes and for lambs kept for stock or for hoggets. In Dorset, where the lambing is exceptionally early, Cabbages are regarded as especially valuable in the last three months of the year, and this crop is obtained from spring sown seed. In folding for use in yards or out on pasture for store cattle, cows, and pigs, Cabbages are equally useful, and as by management they can be had at any special season or throughout the year they are certainly worthy of a more prominent place than is usually given them.

For dairy cows they must be used with care, as cows always consume such succulent food greedily. A moderate quantity daily in winter and early spring used with other food always does good. In summer as pasture grows bare, and in autumn as it becomes less nourishing, Cabbages are a wholesome change, especially if used alternately with tares or green Maize, and there is then no risk of unpleasant flavour in the butter, which there certainly is if cows are allowed to have either as much Cabbage or green Maize as they can eat. In southern counties, where Maize answers as a fodder plant, Cabbages should be sown in April to form a successional crop to it, and for general purposes it is best now to sow early Oxheart with Intermediate and Late Drumhead, as these three fine sorts give an excellent successional supply for a long time in autumn and winter.

On many farms plants from seed sown last August are left in the seed bed all winter. The intention is to leave them in the seed bed till February and then plant out in the field, but very often the planting cannot be done till March in a wet late season, the crop is thus retarded by fully a month. If part of the August sowings are planted out in autumn, then the spring planting forms an admirable succession. Autumn planting is often avoided because of the heavy losses among the plants during winter and the consequent labour of replanting, but it must not be forgotten that much time is lost in this way. A much better plan is to drill the seed on rich land about the middle of August, to run the horse hoe between the rows once or twice after the plants are visible, but not to single the plants till February or March, when any risk of loss will be at an end. By this plan the plants sustain no check, and little, if any, transplanting will be required. The land available for the purpose may have recently been cleared of a crop of winter Oats, which in ordinary seasons are ripe in July, or it may have been foul land cleaned and cropped with Mustard which is either folded or ploughed in. The extra outlay for seed which drilling involves is the only objection, but that is surely well counterbalanced by the more speedy and certain growth, and the avoidance of all the attendant risk and cost of transplanting. When land cannot be had for drilling, then the plants must be raised in a seed bed, a pound of seed so sown being calculated to afford enough plants for an imperial acre. The distance apart of the plants should depend upon the sort as well as upon the condition of the soil. We have known late Drumheads placed 3 feet apart advantageously in a rich loam, and we have found it answer as well in lighter soil to have the rows 30 inches apart, and the plants 20 inches apart in the rows.

The weight of this crop per acre has a wide range, of which the minimum may be placed at 20 tons, and the maximum as high as 40 to 50 tons, and the sight of a huge fully developed "Drumhead," weighing some 40 or 50 lbs., carries conviction with it of the possibility of a crop of the higher weight per acre. No doubt Cabbages are an exhaustive crop, but then so is everything else more or less so; but we have only to bring our cultivation up to the standard of excellence implied by the gigantic fifty pounders, and we shall not care to trouble our heads about "exhaustion." Why, we have even heard objections raised to the cultivation of Winter Oats upon the score of exhaustion, and to all such alarmists we say, Keep the soil well stored with fertility, do not suffer weeds to rob it, and then you need have no fears about exhaustion. Bring a little common sense to bear upon the matter, and it will be obvious that nothing is easier than the regular storage of the soil with plant food upon the simple but indispensable plan of judicious compensation.

WORK ON THE HOME FARM.

In sowing Clover or seeds for mixed layers with spring corn avoid fields infested with Charlock or Poppy seed, because the double crop prevents hoeing, and the rollers are run over the corn and seeds as soon as the plant is well above the surface. Hoeing should be begun early on foul land, and it is here that a really good drill hoe proves so useful. Never waste money upon the purchase of an old drill, but have as strong and perfect an implement as possible; then if you have a set of corn hoes they can be put on the drill now, and much good work be done, much time and labour saved. But the hoes must be uniform in size and position, and the implement well under control, or harm may be done to the corn, and much of the hoeing otherwise badly done. We have seen an entire row of corn spoiled by a loose hoe, and we have seen more than half the weeds missed or only bruised by the hoes. The master or foreman should always watch the working of the hoes for the first turn or two up and down the field, and as frequently as possible afterwards, and a reliable man set to follow the implement. A small field of Carrots should always be sown on every home farm, both for home consumption and for the requirements of the hunting or hackney stables. A few Carrots are always useful for horses, and we consider them indispensable for dairy cows in the last three months of the year. It is of especial importance that the land should be clean as well as fertile, as young Carrot plants are so small that they are soon overgrown by weeds. No soil is without weeds of some sort or other, and hoes must be briskly at work at once after the plants are visible. Quick germination is promoted if the seed is kept damp for about a week before sowing. This is done by thoroughly mixing two bushels of sand with 6 lbs. of seed per acre, taking great care to well separate the seed. Then spread the mass out thinly upon a barn floor, and keep it moist by a slight occasional sprinkling with water. The plant then appears so quickly after the sowing is done that it has a fair start of weeds, and with careful hoeing and singling a full crop is not difficult to obtain. Under good management a crop of Carrots should not prove more expensive than any other root crop, and it is certainly so useful as to be worthy of a little extra care.

REMARKS.

30th.—Unbroken sunshine throughout.

31st.—Brilliant early; fine and generally bright day.

1st.—Cloudy early; bright fine day.

2nd.—Bright throughout.

3rd.—Fine and bright.

4th.—Mild, cloudless day; clear, cold night.

5th.—Mild and bright in the morning; hazy with a little cloud in the afternoon.

A rainless and almost cloudless week, with cold E. and N.E. winds. Mean temperature almost exactly the average, the maxima being high and the minima low.—G. J. SYMONS.

DAFFODILS.

SINCE the times of the old herbalists, or for something like 300 years, Daffodils have been favourites amongst hardy flowers, and for a good portion of that time some of the chief types have been represented in our border plants. The fact that so many produce their flowers with the earliest harbingers of spring would alone have sufficed to insure them prominent attention. But in addition to that, their flowers, even of the oldest varieties, are distinguished by considerable beauty of form, and to this is added, in numerous instances, a delightful fragrance refreshing and never overpowering. When, therefore, amateur or professional gardeners turned their attention to the improvement of such plants the result could in a measure have been foreseen, though it is doubtful if any of those who first engaged in the work adequately realised the character of the progress that would be effected.

Had the admirers of the Daffodil—using that term as a general popular designation for the whole of the *Narcissi*—confined themselves to the introduction of species and varieties found wild in other countries, the group would have been much more limited than it is at the present time. The genus *Narcissus* as represented by its wild forms is not a large one by any means, including less than a score of well-marked species. These too are comparatively local in distribution, being mainly confined to southern Europe. They are, however, extremely variable in a state of nature, and intermediate forms have been found that serve as connecting links between the species, due in some cases probably to hybridisation, and perhaps in others merely to seminal variation without the introduction of related species. We have recently inspected a large collection of imported *Narcissi* of the *Ajax* section, and it was extremely interesting to note the number of distinct forms corresponding to many that have already been named.

This variability is one of the characteristics of the *Amaryllis* family, and when Dean Herbert applied himself to the study of hybridisation amongst the plants constituting that group, it was not surprising that the *Narcissus* should receive a share of attention. The result was, that in a number of experiments made by crossing the species, seedlings were obtained presenting characters so nearly intermediate between those of the parents, as to leave no doubt that they were genuine hybrids. These were probably the first definite attempts to improve the Daffodils, and the success achieved was sufficient to lead other experimenters in the same direction, with the result that considerable additions were made to the forms available for garden culture. It is only within the last twenty years, however, that the range of variation in the Daffodils has been fully demonstrated, and still more recently that the plants have attained to a high degree of popularity. The writings of Mr. J. G. Baker, Mr. F. W. Burbidge, and several amateur contributors to the horticultural Press, have assisted greatly in placing the *Narcissus* in a prominent position amongst hardy plants. Several nurserymen also have made specialties of the plants, have formed large collections, and by frequently exhibiting the flowers at the principal shows have familiarised the public with the soft and harmonious shades and gradations of yellow the varieties present.

As in all cases where plants possess marketable value the effort to secure novelties has led to an influx of varieties which in some cases are so nearly alike that only the keenest connoisseur can

distinguish them. Recognising this difficulty as one that was likely to retard the popularity of the plant the Royal Horticultural Society organised a Daffodil Exhibition and Conference in 1884, with the special objects of at once displaying the characters of the *Narcissus* family, and by the help of a Committee to remove the confusion then rapidly increasing in the nomenclature, and to reduce the "too-much-alike" varieties to fewer types. Good work was effected in this direction, but the lapse of six years has provided the Committee with matters requiring further attention, and it was consequently resolved to arrange for another Exhibition and Conference in the present year. This was opened at Chiswick on Tuesday, and continues until Friday this week, and all who wish to see what has been effected in the improvement of the plant would find themselves well repaid by a journey to Chiswick.

It is not only as a garden plant that the Daffodil has become of importance, the demand for the flowers has created an important industry, and enormous quantities are now sent into the London and other markets during the spring months. Especially in the Scilly Isles has the business been developed, and of the 200 tons of flowers which are said on good authority to be exported thence annually Daffodils form a large proportion. From France and Italy also come early consignments, while to later supplies the home growers about the metropolis contribute largely. A visit to Covent Garden on a market morning in the early spring months, especially about Easter, shows conclusively how important a position the production of Daffodil flowers for sale has assumed, and yet the trade has grown up entirely within the past few years.

The strong points in favour of Daffodil flowers is that they last well when cut. With ordinary care in packing they travel safely, and they are in nearly every case exceptionally well adapted for arranging in vases or bouquets, or for other floral decorations. Some, like the simple and double forms of the Poet's *Narciss*, are unrivalled amongst outdoor flowers for all purposes, even for button-holes, sprays, and wreaths. Still another point is that some members of the family can now be had for fully half the year—namely, from December to the end of May. Many are adapted for culture in pots, are forced early with little trouble, and then, last of all, they are cheap. There is, in consequence, no mystery about the popularity of the plants; but it is to be hoped that reasonable restriction will be placed upon the introduction of so-called novelties, and thus avoid the bewilderment that amateurs are apt to experience when names are multiplied without attendant distinctions in the plants denoted.

Over 500 seedling forms have received names, and may be found in trade catalogues, for the practice has been evidently followed in some cases of naming nearly every seedling raised in which the smallest character could be discerned as a distinction. Where it is desired to form collections as large as possible these may all be worthy of a place, but those who can only provide space for limited number the most distinct only are suitable. It is disappointing to find a supposed novelty so much like others already in our care that they can scarcely be distinguished except by a most careful examination. It is probable that between 600 and 700 names have appeared at different times, but there are at least 500 that have been set down as distinct. Of these 200 are included in the *N. pseudo-Narcissus* group. Of the *N. incomparabilis* and *N. Tazetta* groups there are perhaps 200 together while of the three hybrid types *Leedsii*, *Burbidgei*, and *Barri* there are fifty each.

One purpose for which Daffodils are admirably adapted has not been noticed—namely, for planting in turf on slopes, or under trees. In such positions they are seen to the best advantage, and for several weeks past the mound near the Cumberland Gate of the Royal Gardens, Kew, has been gay with the thousands of Daffodils there planted. In scores of similar places, where few other plants

would thrive under the dead shade of trees, these seem to flourish, and their flowers come at a time when they can be the most appreciated.—L. CASTLE.

CULTURE OF CHICORY.

JUDGING from the questions which are from time to time asked through the horticultural press for information on this subject it would appear that such a valuable salad plant as Chicory is not well known in British gardens. The leaves, though bitter, make a wholesome and appetising small salad when cut quite young, and the blanched growth, known to the French by the name of *Barbe du Capucin*, furnishes an excellent winter salad when dressed in the French style. The heads when stewed and served with butter are nearly, if not quite, as palatable as *Seakale*, which they resemble very much in flavour. As all the garden varieties of the Chicory have originated from the wild plant there is a tendency—more marked in some varieties than in others—to degenerate, so that care should be taken to obtain seed from a carefully selected strain, if not the roots would very likely be worthless for producing heads during the winter and spring months. A deep, light, and ordinary rich soil, such that the best specimens of Carrots, Parsnips, and Beetroot would be expected to result from, is suitable to the growth of Chicory. This having been previously dressed with short manure and deeply dug into it should be trodden over and raked level; then draw drills, running north and south, about 16 inches apart and 2 inches deep, and in these sow the seed thinly any time between the middle of April and the middle of May, closing the soil in the drills with the feet, treading and raking it level afterwards. When the young plants have made a couple of inches of growth thin them out, first at 6 inches in the row, afterwards drawing every alternate plant, should none “go off” in the meantime. Take advantage of showery weather for doing the work, removing seedling weeds at the same time. The Dutch hoe should be run deeply between the rows a few times during the summer and early autumn months, as much with a view to destroying weeds as accelerating growth in the plants. So treated I have known roots of Chicory attain to the size of fairly good specimen Carrots. The finer the roots are the better specimens of *Barbe du Capucin* or blanched growth may be looked for.

TAKING UP AND STORING THE ROOTS.

Towards the end of October or early in November, when the leaves of the plants have decayed, the crop should be taken up with a digging fork, care being taken to injure the roots as little as possible in the operation. They should then be laid in a border in a dry situation, the same depth in the soil as they were before. Before doing this, however, some calculation as to the probable number of roots required for forcing into growth in the Mushroom house, cellar, or shed during the interval from the first week in December to the middle or end of the following February should be made, as the roots required for that purpose may be buried closely together perpendicularly in rows about 6 inches apart, and at the depth indicated. This would take about one-third of the roots. The remainder should be given a distance of 6 inches from plant to plant in the row, and 13 inches between the rows, keeping the crown of the individual roots half an inch above the soil. Early in February place over the plants or roots, or a portion of them at short intervals, improvised troughs, about 9 inches wide, the same in depth, and 8 feet long, the ends being 1 inch above the sides as a means of keeping the board (of the same length and width as the individual boxes), forming the lid in position when covered with sufficient litter, leaves, fern or leaf mould to exclude air, as the assistance of fermenting material is not necessary at this time of year to start growth in the roots. Thus grown Chicory of the finest size and quality is obtained.

A covering of long litter or fern may be put over the laid-in roots during the winter months as a protection from frost. Ten or fifteen days before the first blanched heads of Chicory are required the desired number of roots should be taken up and packed about 4 inches apart in any old shallow boxes that may be at hand, or flower pots 9 to 12 inches in diameter, working any kind of light soil among the roots up to within half an inch of their crowns. Then place the boxes or pots in a Mushroom house or any other convenient place where daylight and frost can be completely shut out from the plants, otherwise the process of blanching will not be thoroughly completed. When the leaves have made a growth of from 7 inches to 9 inches they will be fit for use. Successional batches of roots should be put in to force every ten days or a fortnight, according to the demand and means of production. The same roots if allowed to remain in the boxes and pots will yield a second, though naturally not so fine a crop, of *Barbe du Capucin*.

As everyone desirous of having a supply of blanched leaves of Chicory during the winter months may not possess the necessary Mushroom house, cellar, or shed to produce them in I will give a very simple and at the same time almost natural way of obtaining the object in view. Instead of taking up the roots allow them to remain undisturbed in the ground, simply removing the decayed leaves and any small weeds that may be amongst the plants; then strew a mixture of lime and fresh soot around the crown of the individual plants, and cover a few rows at intervals of a fortnight with troughs or narrow boxes of the description indicated above, covering these with a few feet thick of fermenting leaves. Of course the plants or roots not covered with boxes or pots should be covered with a little litter or fern or sifted coal ashes to prevent them being injured by frost. In this way very satisfactory results in the way of solid, crisp, and well blanched heads of Chicory may be secured. If a constant supply of Chicory should be required for small salading the seed should be sown every three weeks from the middle of April to the middle of October, the supply during the interval from the end of October to the following May being obtained from the blanched leaves. The early and later sowings should be made in a warm situation, the midsummer sowings (from the end of June to the end of August) being made in a rather moist position. In growing Chicory for this purpose the seed should be sown broadcast and thickly. Watering at the roots in dry weather is all that is necessary till the produce is fit for cutting. Do this as soon as the plants have made the first three or four leaves. *Crimson-flaked Chicory* and the *Large-rooted Brussels* (*Witloef*) are the varieties generally cultivated for salading.—H. W. WARD, *Longford Castle, Salisbury*.

AN AMATEUR'S EXPERIENCE WITH ORCHIDS.

[Read by the Rev. F. D. Horner at a meeting of the Wakefield Paxton Society.]

(Continued from page 295.)

TEMPERATURE.

As to temperature, I have never subjected the Orchids to any extreme in the ranges of either heat or cold. I have no really very hard and fast lines in temperatures. Cold winds and bright sun outside will at times run them up and down beyond the normal limits, do what we will, but I take all care to keep well clear of danger point either way. I often stretch a point, or rather a degree or two, for the sake of air, it is so much to these air plants. On frosty nights all the Orchid houses are covered with sheets of strong sacking. I find this a great help and benefit. It saves any forced heating of the pipes, and produces a softer and more kindly and more restful warmth than heated pipes alone. I am sure it is more healthy for the plants to keep cold out than to put so much pipe heat into the house. Besides which, if anything by mischance did go wrong with the fire, or even the boiler itself, on a keen winter's night, the sacking sheets over the glass would save an immense amount of heat from loss by radiation.

As a rule I have kept near the well known temperatures for warm and cool Orchids, only I never have the winter night temperature in the cool houses lower than 50°, and by day 55°. There is no trouble with these in summer but keeping them cool enough, which perhaps we cannot accomplish when outside temperature is 70° in the shade. The warm and intermediate night temperatures in winter are both much the same, about 60°. I take care to keep the *Phalænopsids*, *Vanda Sanderiana*, and some others in the warmest quarters, but all the *Cattleyas*, even *C. citrina*, *Dendrobies*, *Vandas*, *Aerides*, *Angraecums*, and a great mixture of other species winter well, and indeed always grow together. If winter day temperature rises to 65° I try to gain a little fresh air.

In summer day temperatures I think that beyond 75° fresh air is worth much more than greater heat. I have noticed that my warm Orchids grow more slowly than with some other cultivators, but they make very solid growth, and also that I am often late on in the flowering season, but still they come in time. As the Orchids are all close at hand, I have often left the *East Indian* and other warm species with the house open till almost midnight on calm and balmy summer nights—i.e., with an outdoor temperature not under 60°. Of course I have instrumental help in registering degrees of heat and moisture, but we may in part be our own thermometers in Orchids. If ever we feel faint and stifled and uncomfortably heated in an Orchid house, or shivery and cold and draught-smitten, we may be sure that so it is also with the plants themselves. Of course I am assuming that we are in good order and “set right,” like the thermometer. If the houses are comfortable I often never look at the glass.

MANURE.

This savoury, not to say burning question, is one that happily concerns the Orchid grower in a very light and slight degree.

Indeed, the very term "epiphytal," which applies to so many Orchids, because of their growing upon parts of other plants, such as branches of trees, implies not very indirectly that Orchids cannot be very gross and sensual feeders, or require much if any solid food. An epiphyte is a plant that uses another, not for any purely parasitical purpose, as our Mistletoe does, which is rather a mean way of getting a livelihood, but simply as a favourable position, to which it clings by radical attachment, and from whence it can best secure the sufficiency of light and air and moisture that are the sweet and simple necessities of its most temperate life. Such is the epiphytal Orchid, and I have used no manner of manure to mine. Those, however, that are somewhat more terrestrial, and that seem to like some amount of vegetable *débris* to grow among, and may best be managed in pots, with leaf mould and fibry soil among the compost, these seem not to despise a weak solution of liquid manure in their growing season. I indulge a little in this way such Orchids as *Peristeria elata*, *Cymbidium eburneum*, *Mastersoni*, and *Lowi*, *Thunias*, and *Calanthes veratrifolia* and *Veitchii*. I use the clear dark liquid from the farmyard, but scarcely stain clear water with it. Occasionally also, in the summer time, I sprinkle the floors with a solution of this liquid. It seems to help the colour and substance of the leaves and growth, and this is as far as I have gone with manure for Orchids.

SHADING.

The light is so pure in the open country, with the glass kept clean, that I find by the middle of March and until mid-September the sun may be too powerful for the *Phalenopsis*, *Stanhopeas*, and others unable to bear bright sunshine. Anything in flower is, of course, kept shaded, but I have never used any "summer clouds," or other manner of pigments to dim the glass. A dull day, under any sort of shading, is the *perdidi diem* of every Orchid in the house. I have tiffany or other light material in such lengths that some parts of the house can be shaded longer than others. The *Cattleyas* and *Lælias* get the most sun, and the *Vandas*, especially *Sanderiana*, have a fair amount; *Aeides*, *Angræcums*, and *Saccolabiums* have morning and afternoon sun only. However, as soon as the sun shines athwart the rafters in the afternoon, and for a while in the morning, the whole of the warm house has the chequered sunshine.

The plants are allowed to flower where they have grown and budded, I do not try to prolong their bloom in any colder house. If we could have our plants in flower for as long as we liked, I fear we should exhaust them all, and it is some safeguard against our selfishness, a wise check upon the lust of the eye, that we should suffer a more timely touch than ours to fall upon the flower.

Flowers of many Orchids are of immense duration—longer it may be under cultivation than when growing in the open air at home, and I am conscious of having made and repeated the mistake of leaving the flowers too long upon the plant, although beyond keeping them dry and out of the sun, I have not attempted to prolong their lives.

REST.

I have not given any of the warm house Orchids what would be called "a cool dry rest," partly because I have no quiescent vinery or such-like resting place to give them. I am too young in Orchids yet to have any right to speak dogmatically, and would not knowingly do so; but I am not sure that a dry cold is as truly ripening to growth as a moderately dry warmth. I could imagine that a high parched heat might cause some Orchids to shrivel in their rest, though I think nothing short of an oven could make ripe growths of *Dendrobium Bensoniæ* do that. But I should explain that, though the plants at rest are warm and dry, it is not in a parching heat. I am obliged to keep Orchids in all stages of growth together in a much mixed collection, where many species are winter growers. However, I have not found that an atmospheric moisture, congenial to plants in growth, is too damp and exciting for those at rest. I have resting shelves near the glass, with the pipes some feet below, and here the air is a little drier. Here *Cattleyas* and deciduous *Dendrobiums* neither break prematurely into growth nor are short of flower. Here, too, the fat and fleshy *Catasetums*, *Mormodes*, *Cynoches*, and others, alike impatient of moisture when at rest, sleep safe and soundly.

PESTS.

Against all the parasitical enemies of this nature I use simply a mixture of softsoap and tobacco liquor in rain water, and find it sufficient against aphids, thrips and scale. Red spider I am never troubled with, and consider that the constantly damp earth floors and stages greatly help me in keeping up a moistness fatal to the existence of this pest. I have never used fumigation among

Orchids and, by the way, may add here that I never apply the syringe for overhead watering of the plants, but I sponge the leaves when necessary.

I know of no young Orchid growths that are the better for being, accidentally or otherwise, left full of water—at least with me, and the rafters are guarded by zinc channels to avoid the falling of drip. This enemy I utilise by leading the drip to fall upon the pipes, whereby the drops are turned to moisture "for the good of the house." If a paraffin candle or two are expended in being rubbed on the pipes when hot they will not rust for very long indeed afterwards, even if dripped upon, and assume a very good dark brown colour, peculiarly, if I may so say, anti-rustic.

FIG. 39.—NARCISSUS BULBOCODIUM VAR. MONOPHYLLUS (see p. 321).

I use the syringe for damping walls and stages after a drying day, but the only Orchids I do water overhead are *Dendrobium Falconeri* and *Devonianum*, because if a red spider has the chance of a choice he will certainly not overlook such eligible foliage as theirs. Sometimes I have had damage done by vile monsters, emerging perhaps from eggs laid on stems of newly imported plants, and nothing avails against such abominations but hunting them down. I once got some huge grubs with formidable heads out of *Chysis bractescens*, and would have liked to know what they would have been eventually, but I fear we cannot afford to take any interest in clearing up these mysteries beyond that of clearing them out.

POTTING.

I need not say much on this point of culture, because so much has been said, and it is well known that the two great errors in potting or replanting Orchids lie in using too much material other

than crocks, and too much pot room. Roots of the epiphytal Orchid have, like leaves, a love of light and air, and in many species seem never so happy as when wandering where they will out of the pot or basket, and free of the material it contains. This seems mainly useful as a medium for conducting moisture to their highly absorbent surfaces. Roots as of the Vandas I find are never so vigorous and so free as when the crocks are merely surfaced with a bright living layer of sphagnum that admits the air. It requires more attention to watering than a dense mass of it would; but a ready supply and quick passage of water is essential to the welfare of an Orchid root in active growth. Preferably I repot the plants at the time found to be best for each, just as they show signs of fresh growth, but never wait for any time if a plant is out of health. Anything is better than leaving a plant alone, either in ill health or under conditions conducive to it. A sick plant has usually to go into a lesser pot or basket, and a small raft or block is often a better convalescent home than either.

A FRIEND IN THE ORCHID HOUSE.

I would just speak one word for my friend the green tree rog. May his tribe increase, though it never does so in this country. I have provided him with what seemed a desirable family residence. I have grown tropical aquatic plants for him, and made tempting little marshes in shady places, but he has only sat and croaked in them. With the exception of the toad, he is the only legitimate fauna of the Orchid house. The difficulty is to keep him in bounds, as he will get out if possible by any available outlet, such as an ill-fitting door bottom, or unguarded ventilator. All my openings are in the roof near the top, and I have to fix sheets of perforated zinc over the apertures to keep the frogs inside. The holes in the zinc are just large enough to be too small for bees to get through. Bees I found to be an abomination in the Orchid house because of their fertilising the flowers. I have caught many "bumbles" and other bees with the pollinia masses of Orchid flowers projecting on their heads, and they have set many of the flowers, and so shortened the life of fertilised blooms.

The green frog is a night feeder, and so a most welcome devourer of such pests as come forth in the night, and are also active enough to attract his attention. The slug is too slow for him, but he is partial to the woodlouse, and will take the running ant and the untidy spider, whom he arranges to catch while the spider is catching his fly, "thus saving the middleman's profit." Though he largely sleeps through the high day, he is always "at home" to the bluebottle on the buzz. He will also toward evening take amazing pains to secure a gnat, and I have seen him patiently stalk even such small deer as midges.

The tree frog finds himself in food, and drinks of the dews on the glass. I never knew him do act of damage to a flower or a tender growth. He always looks before he leaps, and that is always from one sure foothold to another. He is in no danger of drowning in the watertanks, for he swims well, and can walk out up the perpendicular sides. His feet are only half webbed, with toes provided with suckers that give him a faultless foothold. I take the precaution, however, of guarding the evaporating troughs, through which pipes run, for I feel sure he cannot like getting into hot water.

I cannot here think of inflicting upon you the list of the Orchids in our collection, but I have the books with me, and any one who wishes is welcome to see them afterwards. I am indebted to Mrs. Horner for a correct list, and for many interesting records most carefully and systematically kept, as to the species in bloom by week and month for several years past, and other details.

THE END.

Now I think I have lectured—or papered—long enough, perhaps more. I am conscious that the topics follow in a somewhat chance and motley way, like coloured beads strung haphazard on a thread; but I hope this has not left a confused impression of what I wished to say. If I have written too much, or too much as an enthusiast, you are of those who best will know how to allow for it. To excuse myself by telling you how long it is since I loved flowers would be to take you very far back in my life, for I grew and flowered the first plant to call my own when a child of seven years. It was only a common Tare or Vetch, and I trained it in the nursery window; or, if I might a moment draw aside the blind in a sick room window, it would be to let you see a little child all but given up for death. His empty medicine bottles, however, were by-and-by refilled with water, and pieces of Nasturtium placed in them. My father had put them there for me to amuse me as I got better, and I watched them strike root and grow. For many years after we enjoyed together the culture of florist and other flowers,

and among them were a few Orchids.—F. D. HORNER, *Lowfields, Burton-in-Lonsdale, Kirkby Lonsdale.*

PEACH GROWING IN FLORIDA.

ANYONE accepting "Waldo's" invitation on page 253, and going out without any further information, would be much disappointed

FIG. 40.—NARCISSUS PSEUDO-NARCISSUS BICOLOR EMPRESS (see p. 321).

on reaching Florida. I know something about the requirements of a Peach tree, and have seen them growing, or "attempting" to grow, in Florida, and came away under the impression that Peach growing in that country was not likely to be very successful. Anyone wishing to grow Peaches under similar conditions to those I saw there must plant them in white sand containing only a very trifling addition of decayed vegetable matter, give them a bottom heat of 73° or thereabouts when starting into growth, with roots kept very dry, a dry atmosphere and temperature ranging from

51° to 84°, and bright sunny weather from day to day. I need not tell any English horticulturist what the result would be, and I am sure very few of them would be inclined to start Peach growing under such circumstances.

With much that "Waldo" says I quite agree. The fault lies in the fact that he has not said quite enough in some places. For instance, he seems to have forgotten for a moment that there are no roads in Florida which an Englishman would consider worthy of the name. In their stead there are tracks through the forest which are covered 4 inches in depth with loose sand; there are no stones and it is quite impossible to make roads. Riding or driving is a matter of necessity there, even for short distances, and it takes about twice the time it would do in England to go an equal distance with a load. Anyone who contemplates making a home in Florida should therefore get "located" as near to a railway and a town as is possible, even if the "sand" costs them twice as much for the freehold. This disposes at once of the offer of "land" twelve or fifteen miles from a railroad at 10s. to £1 per acre; it would be very dear in the end if taken as a gift.

I quite agree with "Waldo" that there is a good opening in Florida for gentlemen of capital, but they must have plenty of brains also, and must be very careful about "the capital" when they get there until they can see their way clear to a good investment. Many have gone out and have been very much deceived by unprincipled persons and lost all they possessed. It is not safe to part with any money until one gets there and sees for himself. Americans and others out there have quite a different scale to ours when estimating the advantages of their country, the quality of their fruits, and many other things, which too often is not found out quite soon enough by would-be settlers.

That Florida is no country for a regular farmer is quite true. It is impossible to grow corn or vegetables in most places, and grass worth the name cannot be grown in most parts. I saw some very good pigs, however, notably one fine fellow under a plantation of Bananas. What connection the two had I did not exactly determine, and cannot say if the Bananas assisted the pig or *vice versa*. Strawberries are certainly said to bear from January to June. The crop, however, is something very different from what they bear in our own country. It was very amusing to me to hear an American say he had "shipped" seven quarts, and to find out that they were grown on 1½ acre. This was about the third week in December. I saw the beds on January 17th with some fruit ripe, but they were a long way apart. The owner said he made 2½ dollars—about 10s. 6d.—per quart for the first, but I could easily see a quart would take a long time to find, and although they bear for nearly six months the total weight of the crop would be very little more than would be got in England in one month, and the prices soon come down until they get to 10 cents, or 5d. per quart, and will not pay for sending away any distance. Only very firm-fleshed varieties are grown, as they have to be sent several hundreds of miles to market. The flavour is not so good as our varieties are when well coloured, and when sent any distance they are gathered before they are half coloured.

But places where Strawberries will grow are as a rule few and far between, as it is necessary for them in such a climate as Florida to have water not more than 18 inches below the surface, and some soil as well as sand to grow in. The roots will then be supplied with water to a certain extent by capillary attraction, but even in such positions as these I was told irrigation was almost a necessity at times. Time and space forbid me saying more at present. The country is a most enjoyable one in some parts to anyone fond of natural history in any of its branches, and especially to anyone interested in botany and horticulture, and I hope to say more on the subject at some future time.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

SPRING FLOWERS AT HOME AND ABROAD.

HYACINTHS AND TULIPS.

It is said to be an attribute of the British that they never know when they are beaten, but go on fighting cheerfully, oblivious of the fact that according to every canon of warfare they ought to have given in long before. There is perhaps some truth in this, but excellent as is the trait, it is often wise to admit the truth, and set about studying the enemy's position in order to try and turn the tables on him at a future time. In our mimic battles of flowers this holds good the same as in other matters. To give familiar force to my moral let me come at once to the case in view. It is this. At present at representative spring shows both in England and Holland this year, candour demands the prompt admission that so far as Hyacinth growing is concerned we are beaten right out of the field. Were it a question of one or two points the matter might be debatable, for the flowers have to be carried in the mind's eye from Holland to England, and from England back again to Holland, but with quality quite 50 per cent. inferior the possibility of

error in judgment is precluded, and it is best to accept the fact and devote the time saved from argument to a consideration of the causes which have led up to a result so little gratifying to believers in the "never beaten" theory.

It may be doubted whether, so far as exhibitors are concerned, the Hyacinth holds the place that it did ten years ago in England. Those who recollect when the conservatory at South Kensington was filled with the magnificent groups of these flowers that used to be staged by Messrs. Cutbush & Son, Veitch & Sons, Barr, Carter & Co., B. S. Williams, and others, can realise the best how much the old order has changed. But it might be thought that although the trade growers do not show Hyacinths on the same scale as formerly, the increasing number of amateur cultivators would fill the blank, for it must be admitted that every year the number of these flowers grown in England largely increases. The growth in popularity of the Daffodil has not prevented a rapid advance in the cultivation of Hyacinths. It is home culture only, however, and so the shows are shorn of much of their former beauty. While from the exhibition point of view the Hyacinth has been receding in favour in this country, in Holland it has made a striking advance. When one sees it as it is grown by the Dutchmen now one discovers a development formerly undreamed of, and realises that there are potentialities in Hyacinths not evolved by English growers.

Cultivators in this country need not go far to discover some important

FIG. 41.—NARCISSUS PSEUDO-NARCISSUS VARIETIES:—1, MINIMUS; 2, MINOR; 3, NANUS (see page 321).

points in which they are placed at a great disadvantage with their continental rivals. One of these which has no small weight is the fact that every Dutch bulb grower of any standing has an almost unlimited stock from which to make a selection. Cultivating Hyacinths by hundreds of thousands, he is able to pick out the very best samples from his large collection; moreover, as quantity as well as quality is at his command, he may pot a thousand, or even two thousand bulbs from which to select fifty or a hundred plants for showing. The process is expensive, even though the bulbs are had for nothing; nevertheless, it can be and is practised. Take the other side. An English bulb grower, whether on a large or small scale, has his bulbs to purchase, and though he may, and no doubt will, receive examples of very high quality if he is prepared to pay for them, he does not receive the cream of the Dutchman's stock, and the first cost precludes him from buying on so large a scale as to place himself, so far as regards numbers, on an equality with the former. Unequal conditions therefore govern the contest. The home grower is handicapped from the very first. But clear as this point is in favour of the foreigner, it is not enough to account for the great disparity between collections of prize plants as grown in Holland and those grown in England, and it would seem that in Hyacinth cultivation we have still something to learn before the best results can be achieved. Perhaps we have been content with a moderate level of excellence, and have adhered to an established method of treatment instead of striving for further improvement.

The superiority of the Dutch-grown Hyacinths is not a thing of long standing. At the quinquennial Exhibition at Haarlem in 1885 the Dutch were as far behind their present standard as we are behind it now; and as proof that culture is mainly responsible for the difference, it may be pointed out that they enjoyed the same advantages respecting

quantity and quality of bulbs as they do at the present time. Improved methods of treatment are the prime factors in the change. It may be asked in what respect the superiority of the Dutch to the English Hyacinths is most manifest. They are better in nearly every way. The plants are dwarfer, the foliage more substantial, the spikes considerably larger, and the trusses much more symmetrical and compact. It would be almost impossible to give too high praise to the splendid examples of culture exhibited by Messrs. Byvoet, Kersten, and Van der Horst, or to the excellent specimens of Messrs. M. Van Waveren & Sons at this year's Show. With the exception of the third named these growers are well known to bulb dealers in this country, but they are wholesale vendors only, and therefore unknown to the great majority of those who buy Hyacinths in the United Kingdom. In Holland, in fact throughout the whole of the horticultural trade, their names are as familiar as those of the great English nurserymen are to gardeners here. These growers all exhibited in vastly improved form to their displays in 1885, and it is evident that they have learned much in Hyacinth cultivation for exhibition since then. Probably the culture of the bulbs for sale had monopolised their attention almost exclusively up till that time, and since then they have been devoting a certain amount of time and care to studying their requirements for exhibition. Mr. Van der Horst is a smaller and less known cultivator than those already named, but he had the finest individual examples of all those shown at Haarlem, and had a dozen of the best plants been selected from each collection in the Exhibition for competition he would have achieved a decisive victory. Comparing his selected dozen with, for instance, the twelve with which Mr. J. Douglas secured the first prize at the Royal Botanic Society's Spring Show on March 26th it must be confessed that the English flowers were so far in the rear that had they met in competition they would have been beaten almost pointlessly, although they appeared to be of about the average quality of former years. The Ilford varieties were La Grandesse, King of the Blues, Koh-i-noor, Czar Peter, Vuuroaak, The Sultan, Souvenir de J. H. Veen, and Electra. The first six were shown extensively at Haarlem, and in far superior condition. Mr. Van der Horst's examples of La Grandesse and Czar Peter were magnificent, the trusses being quite 8 inches long, 4½ inches in diameter, and so closely furnished with substantial bells as to impart to the plants a perfect appearance of massive symmetry. And these were by no means the finest examples; they are merely mentioned as affording a direct comparison with the English-grown flowers. Von Schiller and King of the Blues, perhaps the two finest Hyacinths in their respective colours in cultivation, were equal if not superior to them; and far larger than any, if not quite so compactly furnished, were the enormous trusses of Jacques, a new variety, somewhat resembling Gigantea in colour, but a little paler; and the blue Pieneman. The latter is a well-known variety, with very large drooping bells. These magnificent trusses measured 10 inches from base to summit, and were well furnished.

It is important to state that the whole of the preceding remarks as to the Hyacinths at the Dutch Exhibition refer to specimens with only one flower stem. Obviously a clever manipulator might form fine examples by joining two or even three trusses, and this was evident in the classes at the Haarlem Show in which the restriction as to the trusses being confined to a single stem was not made, but these have been left out of consideration, as affording no direct bearing either on the merits of the varieties or the skill employed in their cultivation. In the majority of the classes the stipulation referred to was in force; hence a true idea could be formed both of the comparative qualities of the varieties exhibited and of the condition in which they were capable of being produced by the best treatment.

While it is evident from the manner in which the Dutch Hyacinths are exhibited that the treatment to which they have been subjected is different from our own, it is not easy to ascertain with exactitude the details of culture which are pursued with so much success. If not altogether silent on the question the Dutchman does not, to put the matter mildly, thirst to give information to whomsoever may please to ask. There is no great secret in the matter, but there is something worth knowing, as there is in everything until the nearest approach to perfection has been reached. If questioned he will tell you somewhat vaguely that much experience of the different varieties is requisite in forcing Hyacinths, that to have them by a certain date some require forcing early, others late, and some no forcing at all. This we knew before. But some deviations from English practice may be noted from personal observation. The latter, as preached and practised by the well-known growers before named and others, is briefly to pot good bulbs in 5 or 6-inch pots in October, using a compost of loam, leaf mould, decayed manure, and sand, leaving the tips of the bulbs exposed, and then plunging them for a few weeks in ashes or cocoanut fibre refuse before introducing them to the house. Mr. Douglas's plants above referred to were apparently grown in 6-inch pots. One of the first points which strikes the visitor in respect to the Dutch plants is the extremely small size of pots used. The majority of them were but 4½-inch, some smaller, none larger than 5-inch. Moreover, the bulbs are potted considerably higher than is commonly the case with us. A large grower and prizewinner told me he considered it quite sufficient to half cover the bulbs, and his plants thus treated were remarkably fine, though not the best in the exhibition. Questioned as to the compost, he informed me that the mixture generally used was composed of well decayed leaf mould, thoroughly decayed cow manure, and sand in equal parts. This he considered met every requirement of the plants. There was none of the loam so dear to English gardeners. Firmly potted in

this sustaining and thoroughly porous medium the plants made robust, sturdy, dwarf growth, with foliage as superior to the weak flabby leaves of the plants at the London Show, as were the massive trusses of bloom which rose above them. Sand is the plunging material employed in Holland, as would be guessed from the important part it plays in bulb cultivation for profit, and from the abundant supplies of it on the farms. I more than once expressed my surprise at the small size of pot used, and the reply was that large pots were not necessary to grow fine flowers if the bulbs were potted properly in suitable soil. Possibly the confined root space, allied to the firm rich compost, may be the secret of the dwarf growth and fine spikes of bloom.—W. P. WRIGHT.

(To be continued.)

DENDROBIUM ALBO-SANGUINEUM.

THE above name is suggestive of white and blood red, but neither seems to convey a correct idea of its colour to my mind. The sepals and petals are of a rich cream, and with the exception of the dark spots in the throat the flower is of a uniform character, which is not common in Dendrobiums. The throat spots I have heard described as of a black currant stain, which I think it more resembles than blood. It is a distinctly beautiful large-flowering kind, and appears to be rather infrequently referred to, but this fact alone is not sufficient to justify the assumption of sparse representation in collections generally. It forms a very compact yet sturdy growth, attaining a foot in height, but our recently acquired specimen has not quite attained to this length of growth, but there is a good prospect of it so doing by the end of another year. Its flowers are borne from the ends of the stems, which in our case has been six from a strong and fewer numbers on weaker pseudo-bulbs. Two flower-stalks issue bearing three each, and are slightly scented, possibly a full-grown bulb would give larger numbers than I have quoted. It flowers in an evergreen state, which is a distinct advantage. It is suitable for pot or basket culture, requiring good drainage, peat, and sphagnum. It enjoys abundant moisture and heat during the growing period, and should not be severely dried during winter, but may be kept cool with advantage.

DENDROBIUM JAMESIANUM.

To lovers of white flowers this Dendrobium should have many charms, for it is possessed of exquisite chasteness and beauty. The lip has a peculiar distinctness of its own as to colour—reddish orange. The name of the gentleman this species is honoured to bear, the late Mr. James Veitch, is sufficient proof of its value. The stems, which grow about a foot high, are covered with a black hair-like surface; the flowers, which are produced in pairs, issue from the point of the current growth. It is a good grower and certain flowerer. A small plant purchased from Mr. Cypher of Cheltenham by Mr. John Baily, Frome, a little more than a year ago, has just completed its second course of bloom, and is justly prized for its several good qualities. It lasts several weeks in flower if stood in a somewhat dry warm house, and shaded from the ill-inspiring influence on Orchid flowers—sunshine. It grows well in a pot, which from its moderate vigour need not be large, peat and charcoal with a surfacing of sphagnum moss meeting its requirements as regards the roots. Copious supplies of water should be given, and an evergreen disposition commands water at the roots more or less at all times. Severe resting would result in loss of vitality perhaps not easily restored.

DENDROBIUM SUPERBUM.

This is a very fine spring-flowering Orchid, forming, as it does under generous treatment, very long pseudo-bulbs. It has a vigorous constitution, and is consequently very well suited to the conveniences of amateur growers not having a house set apart for their especial use. It is deciduous and of pendulous habit, a growth which for general convenience demands a basket, as suspended from the roof displays the blooms to far greater advantage than would otherwise be done. We have but a small plant growing on a charred block which last spring were two tiny air-rooted pieces, and though small we have this spring secured several of its striking mauve or purplish blooms in size quite in proportion to that of its growth. In its latter stages the sepals and petals assume much the same twisting character as the blooms of James Salter Chrysanthemum. In Mr. Proctor Baker's garden at Bristol *D. superbum* is grown uncommonly well, one plant

having 100 blooms expanded, another smaller one has given fifty, a total of 200 being made up with these and a few other plants of lesser size. The strongest growth measures 6 feet in length. During the growing season Mr. Archer, the gardener, finds a slight dressing of fish potash given occasionally proves very beneficial and incites a quick growth. Peat, sphagnum moss, and charcoal form a good rooting medium for basket culture, sphagnum being sufficient alone for blocks.

When under this latter treatment water must be applied frequently, either by dipping into an open tank or by syringing while growth is active. Twice a day would not be too often in bright weather. In baskets it must be regulated according to their size. It has a powerful and to some persons not a very agreeable scent, which has been described as that of Rhubarb, but visitors to whom I have submitted blooms with a view of ascertaining the correct scent, one verdict only was returned, and pronounced to be that of Turkey Rhubarb.

D. superbum giganteum is a very superior form both in size and colour. Flowers 6 or 7 inches across are produced of a deeper shade of purple. The growth does not attain the same length as in the species, nor is it so readily increased, but these deficiencies, if they can be so called, are fully surmounted by the superior character of the blooms. In the garden previously referred to a good plant of this has made two growths, each 18 inches long, on which are now expanded thirty of its noble and truly superb blooms. Now that the value of *Dendrobiums* is so fully advanced, the merits of those under notice should not pass unheeded, their distinct colours, largesize, and perfume being sufficient to warrant the bestowal of more extended favours.—W. S., *Frome*.

EVENTS OF THE WEEK.—On Tuesday, April 22nd, the Royal Horticultural Society's Fruit, Floral, and Orchid Committees will meet in the Drill Hall, James Street, Westminster, at 12 noon. The National Auricula Society's Show will be held on the same day in the hall, and at 3 P.M. the Rev. C. Wolley Dod and Mr. Henwood will discourse on "Primulas." We may remind our readers that a meeting will also be held at 1.30 on Tuesday, in the Lindley Library, to discuss the Hall of Horticulture scheme. The Royal Botanic Society's second Spring Show will be held in the Regent's Park Gardens on Wednesday, April 23rd.

— **THE WEATHER IN THE SOUTH** has been somewhat cold during the past week for the time of year, and several slight frosts have been recorded. Fortunately so far the fruit tree flowers do not seem to have suffered, but show of flowers varies greatly in different districts. The early Pear trees are looking well in some gardens.

— **WEATHER IN THE NORTH.**—"B. D." writes from Perthshire:—"April 7th to 14th—Dry, cold winds from the W., latterly from the E. and N.E., have prevailed throughout the week, and in the last four nights frosts of from 2° to 4° on morning of the 11th. A highly favourable seedtime has been secured for our carse (not coarse this time, please) land, and sowing in this quarter is all but finished. The frost is, however, telling on young grass. The planting of Potatoes has begun here and there." Another correspondent sends a similar account from Stirling, adding that snow fell on the 14th inst., and 6° of frost were registered.

— **DEATH OF MR. J. S. MORGAN.**—The name of Mr. Morgan will be familiar to our readers through the periodical references to his gardens at Dover House, Rochampton. They, with the extensive ranges of glass structures, were maintained in the most scrupulously neat manner, and it was a common remark by visitors that they could see nothing that wanted doing. Mr. Morgan was an American banker of enormous wealth, and died suddenly in Italy, leaving fortune estimated at six millions sterling.

— **THE LIVERPOOL SHOW.**—The Exhibition held last week in St. George's Hall was not equal to those previously held by the Association. This, no doubt, is partially due to the late date, and for this the Committee is not responsible, as the Hall could not be had at any earlier date. It may also be due to the spring meetings having been discontinued for a year or two. Although there was a falling off in the

number of competitors for the prizes offered the miscellaneous exhibits were more numerous and varied than usual. The Exhibition was but poorly patronised by the public, and is therefore expected to prove a financial failure.

— **THE HORTICULTURAL CLUB.**—The usual monthly dinner and conversazione took place on Tuesday, April 8th, at the rooms, Hotel Windsor, Victoria Street. The chair was occupied by the Rev. W. Wilks, and there were present besides the Rev. E. Handley, Messrs. Cousens, Druery, Walker, &c., Mr. W. Ingram being the guest of the Club. Afterwards a most interesting paper was read by Mr. C. T. Druery on the "Wonders of Fernland." It was illustrated with some excellent diagrams and some beautiful specimens of dried fronds. The paper dealt very carefully with the germination of Ferns. It was stated that in the case of all Ferns, whether the gigantic Tree Ferns of New Zealand, &c., or the delicate Maidenhair, the spores from whence the plants proceed are absolutely microscopic. He then showed the various methods of

FIG. 42.—NARCISSUS TRIANDRUS ALBUS (see p. 321).

propagation, the ordinary one by spores, and the abnormal ones of bulbules and apospory. It was shown that of all the species of British Ferns there were to be found tasselled or crested forms, and Mr. Druery believed that if the habitats of the foreign Ferns were searched as carefully as our own land has been, similar departures from the normal growth would be found. The paper was a model of what such papers should be—severely correct as to its botany and scientific side, yet delivered in language that any intelligent hearer might understand even although previously unacquainted with the subject. A cordial vote of thanks was given to Mr. Druery for his valuable paper. We may add that Messrs. Thomson of Drumlanrig and Mr. Bruce Findlay of Manchester will be the guests of the Club at a special dinner on the 22nd on the occasion of their receiving the Veitch Memorial medals, and a large gathering of the members is anticipated.

— **THE KEW BULLETIN** for April, 1890, contains notes on CANAIGRE (*RUMEX HYMENOSEPALUM*), a new tanning material, which is said to add "weight to the leather." It is found "in large quantity in the sandy soil on both sides of the Rio Grande and northward over a large portion of Western Texas and New Mexico." The analysis of the root is as follows:—Tannin, 37.48; organic matter, 11.20; water, 12.07; ash, 0.20; and woody fibre, 39.05. Pistachio cultivation in Cyprus is also referred to; several pages are devoted to correspondence relative to Indian sugar; and note about "Mites in Sugar Cane" concludes the number.

— **ROCKETS.**—Rockets and other flowers are sometimes destroyed by caterpillars eating the heart from whence spring the flower stems. A pinch of hellebore powder will effectually prevent this.—W. T.

— **THE WEATHER AND FRUIT BLOSSOM IN KENT.**—A Faversham correspondent writes:—"It is too early to say much about fruit prospects. Plums and Cherries are flowering, but the weather keeps very cold, and we have had several severe frosts. This morning (April 12th) it was very sharp, ice in tubs and pails, and the ground quite crisp at 6 A.M., bright sun after, and I fear some damage must have been done."

— **THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.**—At a committee meeting of the above Society, held at the Caledonian Hotel, on Monday evening, the 14th inst., there was a large attendance. Fifteen new members were elected, and Messrs. Lewis Castle and T. W. Sanders were nominated for election. Mr. F. Q. Lane, The Nurseries, Great Berkhamstead, was elected an honorary member. The Secretary stated that owing to the epidemic of influenza the sick pay for the quarter had been very heavy, but at the present time only one member was on the sick list. He also announced that many members of the Society were anxious for support in establishing a convalescent fund, and brought up a circular which is to be sent to every member inviting co-operation. Letters and suggestions were read from various members relating to the register of gardeners out of employment.

— **INDIAN FORESTRY.**—The Punjab Forest Administration Report for 1888-89 was recently published. During the year 9000 acres were added to the area of gazetted forests in the Multan district. This area was taken up in pursuance of the policy of establishing irrigated plantations in connection with several new canals constructed in what are known as the "Bar" tracts—that is, the dry upland deserts of the Punjab. The number of forest fires increased during the year, and 17,617 acres were burnt as against 10,324 during 1888. The financial results are satisfactory. The net revenue amounted to Rs. 452,846, or nearly half a lakh in excess of the net revenue of the preceding year. The Conservator complains that the Working Plans Branch cannot get on with their work on account of the undermanning of the Department. As a consequence, working plans are only in force over 364 square miles, out of a total of 2000 square miles gazetted and 6000 controlled by the Forest Department. Experiments with exotics were made, but the result was not encouraging. European fruit trees have been introduced in many places with great success.—(Nature.)

— **EALING DISTRICT GARDENERS' IMPROVEMENT SOCIETY.**—The annual dinner of this useful and flourishing Society was held in the Victoria Hall, Ealing, on Friday evening last, the President, E. M. Nelson, Esq., in the chair. There was a large attendance of honorary and ordinary members, evidently deeply interested in gardening, and the chief feature of the evening was the distribution of prizes by Mrs. Nixon. These were in the form of books for plants or other garden produce exhibited at the weekly meetings between September and April. The system adopted is an excellent one, and worthy of extension. The members take what they think good to the meetings, whether one exhibit or a dozen, and three non-exhibitors are appointed to examine them and record the marks of merit to which they are entitled in a book; but no man, however extensive his exhibits, can have more than six marks at one meeting. This is for enabling good men in small gardens to have a fair chance of recognition amongst their friends more favourably circumstanced. The following gardeners obtained the numbers of marks appended, and received books in value accordingly:—Messrs. Long, 80; Greggs, 75; Roberts, 64; Cox, 52; Gate, 46; Baird, 43; Edwards, 34; Simmons, 33; Viner, 16; Dunk, 11, and Meridem 10 marks, this being the minimum number that entitles to a prize. Money prizes were also granted to the successful competitors of essays on Carnations, but their names are not included in the list before us. Mrs. Nelson gracefully complimented the recipients of the several prizes. Excellent speeches were made by the Chairman and Revs. Percy Myles and J. H. Hilliard, also by G. F. Nixon, E. Dawes, and A. Sewell, Esqs., as well as by the Secretary, Mr. E. Chadwick, gardeners and visitors. The gathering was in every way enjoyable and successful.

— **KOLA (COLA ACUMINATA).**—The Paris correspondent of a daily paper sends the following:—"A rival to caffeine as a muscle-bracing and stimulating drug has been found in Kola. Professor Haeckel of Marseilles admits the virtues of caffeine, but he says those of Kola are greater. He used it in the food of members of an Alpine Club, who performed mountaineering feats of an unusual kind without being tired.

The Colonel of the 160th Regiment at Perpignan, dosed by the professor with Kola, made the ascent of the Canigou Mountain near Perpignan to a height of 9137 feet, and felt quite fresh after his climb, which lasted twelve hours. He only halted once, and for twenty minutes, and ate nothing. The 124th Regiment was able last July to accomplish a march of fifteen and a half hours from Laval to Rennes under similar conditions. They covered a distance of seventy-two kilometres, and were able to go much further in the last hour. They walked at the rate of three and three-quarter miles an hour. Kola is better than Oats for giving mettle and staying power to horses. Perhaps the fasting men have got hold of alkaloid of Kola, of which a very small quantity goes a long way." Mr. J. Christy referring to this, stated in a following issue that "at first the supplies in this country did not exceed 1 cwt. per annum, but now it is imported in quantities varying from 1 to 5 tons per month for use as a substitute for Tea and Coffee." The tree is a native of Tropical Africa, and belongs to the same family as the Cocoa (*Sterculiaceæ*). The seeds are said to possess the property of purifying unwholesome water. The nuts have been found to contain more of the alkaloid caffeine than the best Coffee. Specimens can be seen in the Kew Museums.

— **THE ROYAL HORTICULTURAL SOCIETY.**—The following scheme of affiliation of local horticultural societies with the R.H.S. was passed by the Council, April 8th, 1890:—Local societies subscribing £1 ls. will be entitled to—I., Two copies of the "R.H.S. Journal" for circulation amongst the local society's members. II., To nominate one of their members to rank as a £1 ls. Fellow of the R.H.S., with all a £1 ls. Fellow's privileges with the exception of the "Society's Journal." III., One transferable ticket admitting to all the R.H.S.'s meetings and Shows, and which may be used by any members of the local society. IV., To purchase at cost price one silver and one bronze medal of the R.H.S. (a new medal is being struck, and until that is done the price cannot be fixed). Local societies subscribing £2 2s. will be entitled to—I., Four copies of the R.H.S. Journal for circulation. II., To nominate two of their members to rank as £1 ls. Fellows of the R.H.S., &c. III., Three transferable tickets admitting to all R.H.S.'s meetings and shows, &c. IV., To purchase at cost price two silver and two bronze medals of the R.H.S. Local societies are invited to send interesting exhibits and specimens of plants, diseases, &c., to the R.H.S.'s fortnightly meetings of the Floral, Fruit, Orchid, and Scientific Committees, and to correspond with the R.H.S. Secretary on any interesting horticultural subjects or events in their locality. The Secretary of the Royal H.S. will at any time be happy to assist the secretary of any affiliated society in introducing them to horticulturists or specialists able and willing to deliver lectures on interesting subjects before meetings of their local societies.

AMONGST THE DAFFODILS.

LAST week it was announced that the Royal Horticultural Society would hold a Daffodil Conference and Exhibition at Chiswick on April 15th to 18th, and as a consequence Daffodils have afforded the chief subject for consideration this week. The merits of the plants and their gradual rise in public favour are set forth on page 313, but before proceeding to a review of the Exhibition, it may be worth while to glance at the genus *Narcissus* as it is now constituted, and thus indicate the range of variation that exists naturally, and which has been so greatly extended artificially.

A REVIEW OF THE GENUS.

A brief reference to the leading types will suffice to show that, great as the variation is, it is yet combined with a uniformity of essential characters that renders it comparatively easy to recognise a *Narcissus* wherever it is found. Some of the types, however, present so many differences amongst themselves, that they have afforded ample material for the constitution of genera by botanists who are eager to make distinctions of this character. Out of the genus *Narcissus* as it now stands authors have at different times created over a dozen genera, but these are all discarded now, or the names are adopted as the titles of groups or divisions corresponding in some degree with the older genera. Our leading modern authority upon the *Narcissi*, Mr. J. G. Baker, has given much attention to the characters and classification of the species, and his method is now generally adopted. It possesses the rare merit of simplicity in botanical arrangements; it has therefore come within popular comprehension, and is adopted in the majority of trade catalogues. The method is so well known that it is almost unnecessary to remind readers that the characters upon which it is founded are the shape and size of the corona, which forms such a peculiar, and in many cases prominent, portion of a *Narcissus* flower. This is an unusual formation, and is somewhat puzzling to youthful botanists, as, coming between the perianth divisions and the stamens, it seems to take the place of a true corolla. To this eup, corona, coronet, and crown as it is variously

termed, much of the beauty of the Daffodils is due, and it assumes such distinct forms that the characters thus furnished are a readily recognisable means of separating the species into groups.

Three divisions of the genus are adopted, distinguished by the following names:—1, Magni-coronati, in which the corona is "funnel shaped or cylindrical, and as long as the perianth segments," which includes all the bold and handsome "Trumpet Daffodils," some of the finest of the whole genus for garden decoration, rich shades of gold predominating. 2, Medio-coronati, with a cup-shaped corona "about half as long as the perianth segments," comprising the numerous forms of the "Peerless" Daffodil, *Narcissus incomparabilis*, possessing a wide range in more delicate shades of yellow. 3, Parvi-coronati, having "a small saucer-shaped corona," including the charming graceful *N. poeticus* and its countless descendants, the purest white prevailing in the perianth divisions, while the corona often possesses in its margin the nearest approach to scarlet in the whole genus, bright shades of red affording a lively contrast with the quieter tints of the other sections.

Under the three heads named sixteen species and a number of sub-species are grouped, the garden varieties and hybrids having assumed such numeral proportions that they are excluded from a botanical arrangement, though their positions in the system are easily indicated. It would be impossible within the limits of this article to glance even at the leading varieties of the respective types, and it would be unnecessary also, as the most distinct and beautiful are enumerated in the report which follows. It may, however, be interesting to briefly note the species that really constitute the respective types from which the garden varieties have been derived. First in order under the "large crowned" Daffodils we come to the Hoop-Petticoat Narciss, *N. Bulbocodium*, in which the crown is extremely large and the colour ranges from soft yellow to pure white, as in the variety *monophyllus* (fig. 39, page 315). Next in order is the Trumpet Daffodil, *N. Pseudo-Narcissus*, the varieties and hybrids of which now constitute so large a group, mostly with very large coronas differing greatly in tint, but the richest golden tints are most frequent. There is, however, considerable range in size from the giant *maximus* to the diminutive *minimus*. Figs. 40 and 41, pages 316 and 317, indicate the chief characters of this species. Under *N. Pseudo-Narcissus* are now ranked as sub-species several forms that have been assigned a higher rank by older authors. These are *muticus*, a neat flower and good colour; the graceful and interesting *cyclamineus* so long lost to cultivators; major, to which *spurius* and *Telamonius* are related; minor, together with *nanus* and *minimus*; *bicolor*, a fine type, including *Horsefieldi* and *Empress*; *moschatus*, with deflexed flowers, and including some of the best white Daffodils such as *albicans* and the drooping *cernuus*.

With the graceful *N. triandrus* the "medium-crowned" section commences, and the beautiful variety *albus* (fig. 42, page 319) is one of the greatest favourites in the genus, being admirably adapted for culture in pots. The *N. incomparabilis* forms follow, and in the exceptionally large variety *Sir Watkin* (fig. 43) we have a near approach to the *N. Pseudo-Narcissus* forms. The variety *albus expansus* (fig. 44, page 322) is one of the ordinary type of this group. *N. odoratus* and *N. juncifolius* are other species in the same group, but the latter is not so well known as the former, which takes its place as the *Campanelle* in many gardens, and is one of the most esteemed of the fragrant *Narcissi* for forcing purposes.

In the "small-crowned" division the first to be noted is *N. Tazetta*, the "Polyanthus Narciss," which includes large numbers of varieties that have taken their place more amongst "Dutch bulbs" for forcing than as outdoor garden plants. *N. papyraceus* (fig. 45, page 323) is regarded as a sub-species, and is one of the most familiar of market flowers early in the season as the old "Paper White" Narciss. The species *Tazetta* is geographically interesting for its comparatively wide range of distribution, as it is found from Europe to China and Japan. Historically it is also worthy of note as one that has been under cultivation during a number of years in Holland for export to this and other countries with the ordinary bulbs for forcing. *N. intermedius*, a South European species, and *N. gracilis* are old plants, but have been to a considerable extent superseded by newer favourites. *N. viridiflorus* is a curiosity from Morocco and Gibraltar, with green flowers. The *Jonquil*, *N. Jonquilla*, with small golden exquisitely fragrant flowers, is one of the most delightful members of the family, and is everybody's favourite.

Passing *N. serotinus*, *N. elegans*, and *N. biflorus* as species of comparatively little interest, though the last named is sometimes found in old gardens and flowers freely, we come to the Poet's Narciss, *N. poeticus* (fig. 46, page 325), of which the varieties now form a large group, and few amongst the market flowers are more appreciated than the double or *Gardenia* flowered variety of this species, though all are valuable. The last to be enumerated is *N. Broussonetii*, which is chiefly interesting as one that had long been lost in cultivation, but re-found at Morocco and introduced in recent years.

THE HYBRIDS.

Following these the hybrids come under eleven groups, some of which in distinctness of characters almost deserve specific rank. Most of these are of recent production, but those raised by Dean Herbert are especially interesting as the forerunners of many more recent favourites, and as showing some of the leading characters of the types subsequently formed. Seven of these were depicted in the "Botanical Register" for

1843, when Dean Herbert accompanied the descriptions with an account of his experiments in hybridising the *Narcissi*. Two of these have been sketched, and are shown in figs. 47 and 48 (pages 326 and 327). The hybrid (fig. 47) resulted from crossing the wild Yorkshire Daffodil, *N. Pseudo-Narcissus* with *N. poeticus*, and was regarded by Dean Herbert as a variety of the *N. incomparabilis* type. The flowers had white perianth segments, and a yellow corona bright red at the margin and base. In fig. 48 is shown another hybrid also from a variety of *N. Pseudo-Narcissus* crossed with *N. poeticus*, in which a pale yellow tint predominated throughout the flower, the corona having a slightly darker hue. The others showed various degrees of intermediate characters between the species named. Dr. Leeds of Manchester and Mr. W. Backhouse of Darlington succeeded in raising a large number of hybrids, and since these have been placed in commerce several additional types or groups have been created. The following are adopted in Mr. Baker's classification:—*N. Bulbocodium-Pseudo-Narcissus*, a wild hybrid found near

FIG. 43.—NARCISSUS INCOMPARABILIS SIR WATKIN.

Oporto, intermediate between the species as expressed in the names; *N. Humei*, apparently from *N. Pseudo-Narcissus* and *N. poculiformis* (itself a probable hybrid); *N. Backhousei*, from *N. Pseudo-Narcissus* and *incomparabilis*; *N. Macleai*, an introduced plant apparently between *N. Pseudo-Narcissus* and *N. incomparabilis*; *N. juncifolius*, wild, between *N. juncifolius* and *N. triandrus*; *N. poculiformis*, already noted, origin uncertain; *N. Leedsi*, from *poculiformis* or *incomparabilis*, a beautiful group of which there are many forms in cultivation; *N. Barri*, from *N. incomparabilis* and *N. poeticus*, some of the varieties as *N. Barri* *conspicua* are very handsome with highly coloured coronas; *N. orientalis* is thought to be from *N. incomparabilis* and *N. Tazetta*; *N. Burbidgei*, from *N. incomparabilis* and *N. poeticus*, comprises a number of beautiful varieties; and *N. Tazetta-poeticus* is probably from the species named in its title, as it is found growing wild amongst them. From *N. Humei*, *N. Backhousei*, *N. Macleai*, *N. Leedsi*, *N. Barri*, and *N. Burbidgei* the principal recent garden varieties have been obtained, and they include some of the most graceful and soft tinted forms in cultivation. Some scores of these have been named and

authoritatively recognised as distinct, the *N. Barri* and *N. Burbidgei* forms being the most numerous, over 100 having been recorded.

THE CHISWICK EXHIBITION AND CONFERENCE.

The Exhibition in the conservatory was opened on Tuesday at 3 P.M. by H.R.H. Princess Mary, Duchess of Teck, and a number of Fellows assembled to witness the proceedings, and to inspect the Show. The exhibits are not so abundant as was expected, and the absence of amateurs is surprising when it is considered what a large number now cultivate collections of Daffodils. With the exception of the Rev. W. Wilks and Mr. Cowan, the Exhibition is confined to trade displays. These, however, comprised a large number of varieties, and fairly represent the types and forms of the genus. The most notable collections are the following:—

Messrs. J. Veitch & Sons, Chelsea, contribute a handsome collection of Daffodils, representing all the sections provided for in the schedule. No less than eighty-six varieties are included in the Daffodils and fifty-three varieties in the Tazettas or Polyanthus *Narcissi*, one of the finest representative displays of these useful varieties ever staged. All the flowers throughout are distinguished by their size, freshness, and distinctness. Seven new varieties were also shown, nearly all of the Trumpet or bicolor sections. Very distinct is one named *Prodigy*, with sulphur sepals and a gold crown partially contracted at the mouth.

Mr. James Walker, Ham Common, Surrey, has a magnificent collection of flowers and varieties staged in his most tasteful and effective manner. He has 200 neat glasses filled with flowers, twelve or more in each, and there are over 100 varieties. This is one of the best collections that even Mr. Walker has shown. Mr. Poupart, Twickenham, exhibits about 100 varieties of the best Daffodils for market culture. Some very handsome forms are included. Messrs. R. Veitch & Son, Exeter, have a small collection, but including several interesting forms of *N. moschatus* from imported bulbs. Some good forms of useful Daffodils are also included, very notable being *N. triandrus albus*, which comes with five and six flowers on a scape.

Messrs. Barr & Son, King Street, Covent Garden, have a grand collection of 200 varieties, arranged in twelve classes, and they constitute a highly important portion of the Exhibition. A collection of new seedling Daffodils is also shown by Messrs. Barr.

From the Royal Gardens, Kew, comes a most interesting exhibit of 150 varieties arranged in their respective classes, and comprising several interesting varieties. The Rev. W. Wilks, Shirley Vicarage, Croydon, shows a collection of about sixty varieties, all grown in the open ground. The varieties comprise some of the most distinct, and the flowers are of good size, proving that they are well grown. For the silver medals offered by Messrs. Barr & Son, C. W. Cowan, Esq., Valleyfield, Pennycuik, stages collections of fifty and twenty-five varieties of Daffodils. Mr. Cowan also was the only exhibitor in the class for a collection grown by an amateur, and for which the Rev. W. Wilks offered a silver cup as a prize. The varieties are mostly of the *N. incomparabilis* and *N. poeticus* sections, and therefore collectively have a less imposing effect than the Trumpet Daffodils freely used in the other groups.

Some Fellows of the Society were under the impression that the Fruit and Floral Committees were also to meet on Tuesday, and several exhibits were brought that had to be returned at once. Mr. Shoesmith, The Gardens, Shirley Cottage, Croydon, showed twelve grand blooms of *Maréchal Niel* Rose from a plant two years old budded on a seedling Briar, and bearing 800 blooms at the present time. Flowers of *Camellia reticulata*, gathered from the original plant growing in a frame in the Society's garden, were also exhibited. Mr. Miller, Ruxley Lodge Gardens, Esher, sent a box of Mushrooms, and the Stott Company, Deansgate, Manchester, showed samples of their manure and insecticide distributor.

The programme issued for Wednesday included an opening address by Professor Michael Foster, reports of the Committee and Judges, and papers by Messrs. F. W. Burbidge, T. A. Dorrien-Smith, and the Rev. G. H. Engleheart. The arrangements for Thursday (to-day), are as follows:—Admission to the Gardens at eleven. The Conference will be resumed at 2 P.M., Mr. J. G. Baker, F.R.S., in the chair. Papers to be read:—"On the Natural History and Cultivation of the Trumpet Daffodil and its Hybrids," by the Rev. C. Wolley-Dod, M.A.; (Heer Krelage has been asked to read a paper on "*Polyanthus Narcissi*"); "On Irish Varieties of Daffodils, with special reference to the White Forms," by Mr. John T. Bennett-Poë; "Notes on Seedlings and Seedling Raising," by the Rev. G. H. Engleheart, M.A.; "Daffodils for the London Market," by Mr. James Walker. On Friday, April 18th, the Exhibition will close at 4 P.M.

A SELECTION OF VARIETIES.

The types and the species of Daffodils have been enumerated in the preceding notes, and it now only remains to point out a few of the best varieties shown in the respective classes.

Narcissus Bulbocodium varieties.—Conspicuous, the Large Yellow Hoop Petticoat, deep gold, very handsome; *citrinus*, or Large Sulphur Hoop Petticoat, a delicate pale tint; *tenuifolia*, or the Small Yellow Hoop Petticoat, similar in colour to the Large Yellow, but much smaller, as in the variety minor of the *Pseudo-Narcissus* type.

N. Pseudo-Narcissus Ajax.—*Maximus*, rich yellow, large trumpet; *Emperor*, pale yellow sepals and deeper trumpet; *Glory of Leiden*, one of the *Emperor* type, but larger; *Spurius Golden Spur*, rich yellow, large lobed trumpet; *M. J. Berkeley*, sepals deep yellow, trumpet large; *Captain Nelson*, sepals bright yellow, trumpet broad and open;

Her Majesty, light yellow, trumpet serrated; *Hudibras*, clear yellow sepals, deeper trumpet; *Spurius Henry Irving*, large yellow sepals, bright, with handsome trumpet; *Johnstoni* Mrs. G. Cammell, a charming shade of soft yellow and excellent form, a variety collected by Mr. Barr in northern Spain in 1888; *Blondin*, a fine variety, flowers large, sepals yellow, trumpet deeper; *Countess of Annesley*, sulphur

FIG. 44.—*NARCISSUS INCOMPARABILIS ALBUS EXPANSUS* (sec p. 321).

sepals, deep yellow trumpet; *obvallaris*, the Tenby Daffodil, of medium size, excellent shape, and rich yellow; and *John Nelson*, somewhat drooping, deep yellow.

Bicolors.—*J. B. M. Camm*, white sepals, primrose trumpet; *Empress*, white sepals, gold trumpet; *Michael Foster*, creamy sepals, rich yellow trumpet; *Dean Herbert*, pale yellow sepals, gold trumpet; *Horsfieldi*, white sepals, deep yellow trumpet; *James Walker*, creamy sepals, yellow trumpet, fine flower; *Harrison Weir*, white sepals, pale yellow trumpet.

White or Sulphur-coloured Varieties.—These are all elegant and delicate, the following especially so:—*Mrs. J. B. M. Camm*, *Sir Stafford Northcote*, *Lady Grosvenor*, *F. W. Burbidge*, *Dr. Hogg*, *cernuus pulcher*,

Colleen Bawn, tortuosus, Madame de Graaff, very handsome, white sepals and pale yellow corona of capital form; Minnie Warren, moschatus of Haworth, Mrs. Vincent, Snowflake, albicans, and William Goldring.

N. incomparabilis Varieties.—Mostly with sulphur or yellow sepals and deeper coronas. C. J. Backhouse, King of the Netherlands, Sir Watkin, Cynosure, Autocrat, Hogarth, Beauty, Gloria Mundi, Queen Sophia, very handsome large expanded corona, orange, pale sulphur petals; Frank Miles, Maurice Vilmorin, creamy sepals, rich orange corona, fading to the base.

N. Barri Varieties.—With yellow sepals and broad spreading orange corona. Sensation, Flora Wilson, William Ingram, Mrs. Dyer, Conspicuous, one of the best varieties in cultivation; Miriam Barton, Crown Prince, and Maurice Vilmorin.

N. Leedsii Varieties.—Charming pale creamy or white varieties, very delicate. Duchess of Westminster, Princess of Wales, Duchess of Brabant, Palmerston, Beatrice, Gem, Mrs. Langtry, Grand Duchess, Marie Magdalene de Graaff, and Katherine Spurrell.

N. Humei and other varieties.—One class is devoted to the varieties of Humei, Backhousei, Nelsoni, montanus, Macleai, Sabini, Barnardi, and tridymus. Of Humei there are not many representatives, one termed Hume's Giant differs chiefly from the type in the large size of the flowers. Backhousei also is not in strong force, but two varieties are notable—i.e., Wolley Dod, an excellent form with large flowers, fresh pale yellow sepals, and rich yellow corona, and William Wilks, which has more colour in the corona, with an undulated margin. Two varieties of Nelsoni attract attention—viz., Mrs. C. J. Backhouse, white sepals, the corona open and bright yellow, and aurantius, white sepals and deep orange corona. Examples also occur in several collections of *N. montanus*, *N. Macleai*, and *N. tridymus*, one of the last-named, termed Dr. M. T. Masters, being selected as distinct. Though class 7 is specially reserved for the graceful *N. triandrus*, it is not largely represented; the variety *albus*, with pure white flowers, bell-like coronas, and reflexed sepals is charming.

The N. poeticus and N. Burbidgei varieties.—Of the Pheasant's Eye or Poet's Narciss the varieties *ornatus*, *poetarum*, *tripodalis*, *angustifolius*, and *radiiflorus* are taken nearly in the order of merit, the first being extremely beautiful, the floral form excellent. Several of the *N. Burbidgei* varieties closely resemble *N. poeticus*. Some of the best are Baroness Heath, Ellen Barr, Mary, Falstaff, Princess Louise, Dandy, Mercy Foster, Crown Princess, Constance, and Model. The *Campernelle*, *N. odorus*, the *Jonquil*, *N. jonquilla*, and the distinct little *N. juncifolius* are included in this group.

N. Tazetta varieties.—Examples of these are scattered through several collections, but the Chelsea exhibit is the largest and best. The leading varieties are *Soleil d'Or*, yellow sepals, deep orange cup; *Grand Monarque*, white sepals, lemon cup; *White Pearl*, white sepals, creamy cup; *Sir Isaac Newton*, yellow sepals, orange cup; *Verlina*, yellow sepals, deep orange cup; *Bathurst*, bright yellow sepals, pale gold cup; and *Bazelman major*, large flowers, white sepals, orange cup.

Double Varieties.—Perhaps the only double Daffodils that possess any real claims to beauty are the old forms of *N. incomparabilis* and the *Gardenia*-flowered double *N. poeticus*, the last named being far the best of all. The former comprise the "Codlins and Cream," "Eggs and Bacon," and "Butter and Eggs," as they are familiarly termed by many in preference to such learned designations as *aurantius plenus*, *albus plenus*, *sulphureus*, &c. Other double varieties are *N. capax plenus*, *N. lobularis plenus*, *N. Telamonius plenus*, *N. odorus plenus*, and *N. cernuus plenus*, all yellow with the exception of the last, which is white. These are all included in the collections at Chiswick. New varieties were shown by several exhibitors, and submitted to the Committee, but their awards must be deferred until next issue.

NOTES ON FRUIT TREES—APPLES.

(Continued from page 296.)

SOIL AND SITUATION.

"Loose methods, unsystematic, unbusiness-like procedure," writes Mr. Wright in the introduction of his prize essay "Profitable Fruit Growing," page 3, must give place to "sounder principles and more intelligent lines" of culture if the time is to come when "we shall to a far greater extent than now, and far more creditably, share in providing our population with the most wholesome of food, which will be increasingly required—fruit; the outcome of home effort and well applied labour in British gardens and orchards." Those are sentences full of meaning and importance, every one of which I endorse, and I would beg to express my opinion (it may seem late and tardy) of the work itself—viz., "Profitable Fruit Growing," that it is a mine of sound information and practical guidance on hardy fruit culture, which the most experienced may consult.

Soils are a compound of organic and inorganic elements, the mineral being the original. The inorganic substances in the soil are derived from the degradation or decomposition of rocks by the action of air, water, frost, grinding by glaciers, and chemical as well as mechanical action; and the organic are mainly due to the decay of animal or vegetable matter, and are subsequent to the inorganic, therefore must have a conversionary action, as the first forms of

organic life had to live on soils destitute of organic remains. Gardeners set much store on humus, the result of a gradual decomposition of animal or vegetable remains, but it is evident that the first plants which grew on the earth had other sources than humus from which they derived carbon. Carbonic acid, water, and oxygen acting on granite, in which are associated three distinct minerals—quartz, mica, and felspar—disintegrated, form the basis of a fertile soil.

The inorganic basis of soils consists of substances derived from

FIG. 45.—NARCISSUS TAZETTA PAPYRACEUS (see page 321).

various kinds of rocks, the bulk of which are silica, clay, and lime mixed in no definite proportion. They afford, together with organic remains independently of saline matters, a diversity of soils. For technical purposes soils are classified, but for our purpose it will only be necessary to refer to those most in vogue with cultivators—viz., the indefinite terms sandy, clayey, marly, and calcareous. Sandy soils are extremely porous, afford a ready passage to air and water, as well as to the roots of plants, being warm and dry. When they consist of little lime, alumina, or humus, the sand mixed with gravel, they are very poor, yet with an addition of 3 to 5 per cent. of humus become available for root crops. With an addition of clay or marl sandy soils are rendered more compact, retain moisture for a longer period, manuring is more efficient; still they are too poverty stricken to be of use for fruit trees without incurring expenditure in fresh soil and humus-forming substances for which commercially considered there is no adequate return. Nothing short of loamy sands should content the

fruit grower, and though some are admirable for vegetable crops, particularly when deep, they may from containing less than 20 per cent. of clay not be staying enough for fruit trees. Sandy loams, containing 20 to 30 per cent. of clay, and not much less than 5 per cent. each of lime and humus, are admirable Apple soils when not impregnated with excessive amounts of oxide of iron. All sandy loams require manuring correspondingly heavier and oftener than clay soils. Loams are sandy when the silicious matter predominates, and clayey when the clay is ascendant. A strong loam consists of 30 to 50 per cent. of clay, and less, or not more than 5 per cent. each of lime and humus, the remainder sand and other substances. Such form admirable soils for orchards and fruit gardens.

Clay soils contain above 50 per cent. of clay—a combination of silica with alumina, and quickly absorb water, oils, and fatty substances, retaining of water 70 per cent. without allowing it to drop away, and when only moderately moist, but compact, water penetrates it but slowly. Clay dries slowly, shrinks, cracks, readily takes up humus and humic acid, which seem to combine partly chemically and partly adhesively, in result remaining durably fertile. Clay also contains other substances, such as oxide of iron, free and insoluble silica, lime, magnesia, potash, soda, &c. Oxidation of iron gives colours to clays—protoxide brown, peroxide red, and hydrated protoxide blue or greenish. Clay soils are unfitted for fruit trees until weathered, improved by draining, liming, deep stirring, and manuring. When subjected to cultivation so as to have a foot in depth or more of ameliorated sufficiently porous soil to allow heat, air, and water to enter freely, clays become very productive and are not so soon exhausted as loams.

Marly soils are not so retentive of moisture as clay, nor so porous as calcareous soils. Clay marls, consisting of 50 per cent. or more clay, are too stiff for fruit trees; but, containing more soluble silica than perhaps any other soil, they are very suitable for mixing with soils that are too light and porous, requiring more compactness and staying power to fit them for the production of stone fruit, and are particularly valuable in cases of gumming, where lime is not always effectual, though, I apprehend, a deficiency of soluble silica. Loamy marl is perhaps the most suitable soil for fruit trees, particularly of the stone kind, and ensures heavy crops with profitable returns for the manurial agents employed. Sandy marls are not suitable for fruit trees, though worked and darkened by manuring or humus they afford an excellent medium for early crops.

Calcareous soils vary greatly in nature and texture. When sandy they are too light, though not so liable to burn as silicious soils, and when clayey are cold and wet; but when a considerable quantity of clay and sand enters into their composition, as occurs when the chalk base is covered with a loamy deposit, the soil is fertile, and one that drought does not readily affect. Generally calcareous soils are or may be rendered available for fruit culture, particularly stone fruits.

The Apple, though it will thrive in many or most soils, succeeds best, lives longest, and produces the finest and most satisfactory crops on a good loam, substantial, inclining to clay rather than sand. In all cases the less the iron the better they will thrive. In hot soils the trees are subject to canker, and to die back at the points or extremities of the shoots; whilst in heavy cold soils they are similarly affected, though from anomaly of cause and otherwise become diseased, moss and lichen covered. Marly soils suit the Apple well, and soils that are not naturally calcareous are improved by an addition of marl—clay marl to hot sandy soils, and sandy marl to heavy soils.

Soils owe much of their suitability for special purposes to their depth. For the Apple it ought not to be less than 18 inches, with an equal thickness of yellow loam resting on gravel, which will render drainage unnecessary. It is imperative that water should not lodge nearer the surface than 3 feet, or it must be disposed of by efficient drainage, and the soil must be sufficiently porous to allow of the water passing through it and superfluity passing away by the natural or artificial drainage. If there be a pan, as not unfrequently occurs, between the ameliorated and under strata of the soil, it must be broken, than which nothing is better than trenching, but in no case bring up the bottom soil and bury the top soil. Merely trenching as deeply as the good soil extends is a fallacious proceeding, so far as relates to getting warmth, air, and moisture into it. Trees thrive well for a time under such conditions. They reach the fruiting stage, and then do not progress satisfactorily; the roots have passed into undisturbed soil when it was soft and moist, and in a dry hot summer they thrive amazingly, but only for a time, as the roots soon draw from it all its available moisture, and it becomes a compact dry mass, and remains so indefinitely; and the roots, enticed down by the moisture, having nothing to draw from, fail in the supply of sap when the demands are greatest; the trees show signs of the privation, the fruits being inadequately fed are inferior in size and quality. When the

stratum of under loam or pan is broken up the soil is more readily moistened than the compact mass, rain having free access among the loose particles, and the roots penetrate it freely. There is no danger of the natural soil being too rich, provided it be porous and efficiently drained. Deep soils are sometimes objectionable when loose and rich, but such do not occur very often naturally, and soils that are naturally porous to a depth of 3 feet obviously do not require moving beyond that required for tillage operations, as by loosening we increase the liability to luxuriance, and a shallow rich surface soil on a poor hard bottom is objectionable, as it tends to a luxuriance in moist periods which cannot be sustained in dry. A deep rich soil may not induce over-luxuriance through the favourable conditions in which the roots are placed when once the trees come into bearing, and it is a point of some consequence to get the trees away quickly, so that they may make the necessary growth for fruit production, and sustain it afterwards, so that a good soil well loosened is absolutely essential.

Trenching is an operation very little practised in fruit gardens and less in orchards, or rather where fruit trees are intended to be planted. It is considered unnecessary, a hole merely being formed and a tree stuck in. Except where the soil is naturally of a porous nature to a good depth and naturally rich, fruit never will be satisfactorily grown. Were the soil properly stirred in the first instance larger trees, and more as well as finer fruit, will be had in ten years than will be the case in twenty years where it has been neglected. Over-luxuriance is not to be encouraged, but promote a healthy vigorous growth. It follows that a tree making twice the quantity of wood and foliage that another tree produces will attain to double the size, and will bear double the quantity of fruit; although it may not commence bearing so early, yet it will be always marked by greater and superior produce. Manuring, except in the case of poor soils, should be avoided, as obviously but a small portion of it can be needed in the case of standard trees, and in the case of dwarfs it may tend to over-luxuriance unless the soil be poor, when of course manure is essential to enable growth to be made, insuring of and sustaining early bearing. Some good compost will in most cases be desirable at planting, a barrowload or more to each tree, and this in a naturally fertile soil is all the manure required until the trees come into bearing, when it can be applied in accordance with existing exigencies, there being no fear of loss or damage, as solid matter can be put on in winter if that form is desirable, and artificials readily applied at any time, a combination of both being perhaps most desirable for the continued free production of foliage and fertility of the trees.

In wet, cold, and even shallow soils it has been a practice (immemorable for what is known to the contrary) to plant the trees in raised mounds. This plan answers admirably for a time, as it is obvious that when the roots extend beyond the mounds they will pass into the unsuitable strata in quest of moisture when it is deficient near the top, and the evil day is only put off, not prevented. Either the mounds must be extended as the roots extend, or why they should not strike into the unfavourable strata the mounds were made to prevent when they get beyond the mounds it is difficult to see, unless drainage has been had recourse to in the first instance, and the mounds are only intended to supply the trees with a more suitable rooting area and keep them from the disadvantages of an hitherto wet cold soil until it has been made drier by drainage and its surface ameliorated, and depth of soil increased by cultural operations. Then I raise no objection to planting in mounds where the soil is wet or cold, but in any case the causes that make it both must be promptly rectified, and it is a question whether it would not be better to first rid the soil of its cause or causes of unsuitability for fruit culture as testified by the mound planting, and the soil being made suitable high planting would not only be unnecessary but highly objectionable. There are cases when the mound-planting may be desirable from opposite cause—viz., when the soil is shallow and the trees liable to drought. It may seem paradoxical to make hills to retain moisture, but it is a fact that soil is absorbent and retentive proportionately to its depth, the constituents being the same, and that planting on hillocks renders fruit culture practical where it could not otherwise be attempted through insufficient depth of soil. The principal point is to add to the sides of the hillocks, as the roots extend, and by artificial waterings make good Nature's deficiencies; and it is remarkable that the base of these mounds is always more moist than the general or level ground, which, whether it be for the attractive power of the mounds or of the moisture that accumulates at the foot of eminences, it is certain moisture is secured to the extremities of the roots, when it matters little if the soil be dry near the stem.

When the surface inclines sharply, ridges formed transversely on the slope—each row of trees elevated on convex ridges with a sort of valley between—rain will be prevented running off when

it falls thick and fast for a brief period, as often happens in thunderstorms when the ground is parched, and accumulating in the valleys the strata beneath will be moistened, and thus supplied to the extremities of the roots, the effects will be felt at the extremities of the shoots; they will not perish or become stunted as in a dry parched soil, the foliage will be kept fresh and the fruit better fed.—G. ABBEY.

(To be continued.)

TOMATO DISEASE.

A SHORT time since an article was contributed by Mr. Bardney on "Tomato Disease, its Cause and Prevention," and having, like hundreds of other large and small growers, been greatly inconvenienced by the attacks of this disease during the past season or two, the heading rivetted attention at once. In my eagerness to grasp the treatment of the leaf fungus, the first portion of the subject treating on root-clubbing was passed over lightly, but I must confess I was disappointed in the advice given by so able an exponent, and my exception is not a solitary one, for I have inquired the opinion of other and greater authorities than myself, who expressed a similar view. Several causes are assigned for the attack, but I think there is some doubt as to the efficacy of the remedies advanced. To strengthen my view of this argument, I would ask Mr. Bardney the reason why the large Channel Islands and other market growers who make them so great a speciality, should be so baffled in their attempts to check and overcome its virulent attacks? I am told some have given up their culture for a season or two in order to try and rid themselves of the foe, and then only, with partial success.

Mr. Bardney says it can and must be stopped at once, for it soon communicates itself to healthy plants if the treatment is not changed and a remedy applied. Sulphur is the remedy advocated, applied in the form of solution, made by mixing a 4-inch potful in three or four gallons of water, previously removing any infested leaves or stems. If so simple an application is a remedy, it appears strange that it should prove so dreaded and formidable a disease, and it is certain if it were effectual at Norris Green it is not so with many growers.

I was privileged last spring to inspect what was to me one of the most remarkable examples of successful Tomato culture I have ever seen. The plants were growing in houses with the most complete system of ventilation, and under the care of a man of the best reputation as a painstaking and thoroughly practical gardener. They were grown for market purposes. On being interviewed in the autumn it transpired that fairly good profits were realised, but nothing like the returns were made that might have been had were it not for the Tomato disease. I feel sure that fluctuations of temperature to which your correspondent attaches so much importance could not have caused the failure in this instance.

Last year proved very variable as regards disease with Tomatoes indoors, for it was a common observation that in one garden no trouble was given, while in another in the same district, and perhaps closely adjoining, the crops were very light. A solid growth, built up without the aid of animal manure, will admittedly be less liable to the attack, and a warm but freely ventilated house will add another important provision in escaping disease; and even with these indispensable factors some untoward influence will sometimes interfere to thwart the energies alike of plants and cultivators. We have some strong plants which were growing, flowering, and setting fruits satisfactorily in pots in a mixed plant stove, and I have just discovered that the most forward are affected by the disease that attacks the fruits. They occupy positions where roof space is not otherwise utilised, some being on a shelf directly beneath the ventilator, and these were the earliest victims. But for the danger of extending the disease to summer crops I should remove them to other and more airy quarters. Probably a moist atmosphere combined with the heat contracted by the unusual brightness of the sun may to some extent account for it, and a slight shade now put on will command a more equable and, it is hoped, a more favourable temperature. I had hoped so important a topic would have "drawn out" additional information, and I fear my views and remarks on the subject are crude, as my chances of gaining practical knowledge are not so favourable as I could wish.—W. S.

FRUIT PROSPECTS.

THE promise of Apples here is good on the whole. Peasgood's Nonesuch has the least fruit buds, and Ecklinville Seedling, Stirling Castle, Potts' Seedling, Worcester Pearmain, Mother Apple, Ribston Pippin, Cox's Orange, Margil, and King of the Pippins are very promising. Other varieties have quite sufficient bloom buds to produce a very fair crop. Pears in the open are with one exception (Marie Louise d'Uccle) a failure, as they have not recovered from the caterpillar plague of last year. Evidently it takes them longer to regain their strength than Apples. Plums promise a fair crop, in fact plenty of fruit, as a moderate amount of blossom is much better in my opinion than a great quantity. Our collection of Plums is large, and all appear satisfactory. Birds took a special fancy to Black Diamond, and took nearly all the fruit buds. Victorias and others have not been interfered with to any extent. Cherries on walls are full of blossom. Peaches and Nectarines are now a mass of flowers, and so far I think they are uninjured by frost. Apricots an average promise, and the blooms are

setting well. I should mention that Pears on the walls are showing more blossom than usual, Marie Louise, Flemish Beauty, Baronne de Mello, and Beurré d'Amanlis having the most fruit buds. The outlook is decidedly encouraging, and through our efforts the insect pests are nothing like so bad as last year. We find that the season is earlier by about three weeks than last year, most of the trees being from sixteen to twenty-three days earlier by referring to notes made each season as trees expand their flowers.—S. T. WRIGHT, *Gleuston Court Gardens, Ross.*

As readers are invited to send observations respecting the promise of fruit this season from various localities I gladly send a few notes. In

FIG. 46.—NARCISSUS POETICUS (see page 321).

the first place I venture to predict that few readers of the Journal will be able to fix in their minds the latitude and longitude of the little village usually called "The Bank" (Astwood Bank), which has always been noted for its intense interest in horticultural pursuits, and especially in its annual flower show, so much so that at a recent gathering a leading exhibitor from a distance declared that the Astwood Show was "the best in Worcestershire, Warwickshire, or any other shire of its class." The exhibitors consist chiefly of working amateur gardeners and well-to-do cottagers who are employed in the needle factories, and work their gardens and allotments morning and evening. The locality may briefly be fixed about midway between Worcester and Warwick east and west, and Birmingham and Evesham north and south. The situation is high, dry and exposed, particularly to east and westerly winds, consequently late frosts are not, as a rule, so damaging as in low-lying districts, and there is usually a visible difference in vegetation of nearly a fortnight between Evesham and Astwood, although only a little over a dozen miles apart. On a visit to Evesham last week it was

noticed that the Plum trees in favoured spots were as white as snow with blossom, while a week later the Astwood trees are not yet open, and fortunately too from the reports of the frost, which are very discouraging.

Apricots are much damaged by the late frosts, and most of the blossom has failed to set, except such as happened to touch the walls, which appear to have retained sufficient warmth from the sun in the day to protect the young fruit, a circumstance that may well be noted—to nail-in close.

Plums on walls are not as well flowered as usual. In the open, as also Damsons, a fair bloom was promised, but the bullfinches, in spite of all my efforts, nearly cleared the trees. Most of the damage was done in one week, when the influenza was responsible for me not being able to use the gun. Over fifty were caught, and a few shot. There is this redeeming feature about the loss of fruit—I turned most of the birds into money by selling somewhere about 25s. worth, besides keeping a few beauties for cages.

Apple and Pear trees show a promising number of flower buds, but besides being forward and liable to damage later on from frosts we have an unusual quantity of enemies to battle with. The caterpillars of the winter moths are fast hatching out on neglected trees, aphides are unusually plentiful for this season of the year, red spider is likely to be enormously represented, as mere boughs are literally red over with eggs in some cases. Here is also another insect fast hatching, the name of which I am not sure about, but believe it is spelt "Cherino" or Pyslla (?). The crops I fear will be dearly bought by the attention and materials required to do battle with such an army as confronts us. I have some thousands of caterpillars hatched out in pound glass honey jars for experimenting with.

Gooseberry trees are almost stripped of fruit buds by sparrows and bullfinches, in spite of syringing with petroleum and dusting with lime and soot. Currant bushes not much harmed.

As a determined precaution against insect enemies I am placing some of the smaller Apple trees in a bath composed of lime, cow-dung, and clay, with a little petroleum and softsoap well dissolved and thoroughly mixed in the compound. By using two brushes (one in each hand as a support) it is not so formidable an operation as may at first glance seem. This effectually shuts up caterpillars and eggs, red spider, scale, aphides, American blight if any, and a host of other minute pests visible with the microscope. The buds open out of the mixture clear and free from pests.—J. HAM, *Astwood Bank, Worcestershire*.

OUR garden is situated about $4\frac{1}{2}$ miles from the river Humber, and is probably about 80 feet above high water level. The soil is a light sandy loam overlying red sand. Nearly the whole of the fruit trees have been planted during the last twenty years, and thrive fairly well.

The following is a summary of the prospect of fruit with us. Apricots on south-east aspect plenty of bloom and apparently an average crop set. Apples—Cox's Orange Pippin on dwarf trees, full; Ribston Pippin, medium; Lord Nelson Codlin, full; this variety does remarkably well here, and is a long way before Keswick Codlin as a market Apple, but does not produce such handsome fruits as Lord Suffield, which, as well as the Keswick, are very promising. Warner's King on trees about nine years planted are showing well, as is also Stirling Castle. Several other varieties are only medium this season. Of Pears, Jargonelle on the wall is full of flower trusses just ready to expand; Louise Bonne of Jersey, very full of buds on pyramid trees; D'urondeau does well here in most seasons and is again very promising. We have a tree of Winter Nelis on a wall which covers a space about 18 feet by 12, which will soon be a fine sight, aspect south. Williams' Bon Chrétien are very full on bush trees. A large old Hesse Pear tree has very little blossom showing, whilst on the other hand a large old tree of the Green Chisel is full of buds; this tree is more admired for its fine appearance than its fruit.

Plums were a heavy crop here last year, but there is only a small show of blossom this; Victoria, Dennison's, Rivers' Early, Pond's Seedling, and one or two other varieties are the best on the walls. Nearly all varieties in the open very thin. Peaches, plenty of blossom fully expanded, but I fear will be injured, as we had from 4° to 6° of frost every night last week. Cherries, both dessert and Morellos, are showing plenty of bloom, as also are Siberian Crabs. Gooseberries have suffered more from bullfinches this winter than for several years past. Black Currants are showing a fair amount of bloom where they are tolerably clear of the mite, which is more the exception than the rule in this locality.—W. W., *Brough, East Yorks*.

GARDEN PRIMROSES FOR SPRING BEDDING.

As spring flowering plants these have few rivals for filling flower beds during the winter and spring, and although such conspicuous masses as given in *Myosotis*, *Silenes*, and *Wallflowers* are wanting, they are none the less appreciated. From a packet of seed a great many plants may be secured, and, like some other among florists' flowers, scarcely two will be found alike, which makes them all the more interesting. They are hardy and precocious, as only severe frosts will cause a break in the display, which is again resumed immediately on the change of weather. Seeds may be sown during the next two months, choosing a shady aspect, having a fine and rich soil. For the convenience of bedding and securing a maximum amount of bloom, there is a decided advantage in sowing the seeds at once, and treating them

similarly to other annual seeds which are sown in spring for the summer and autumn display.

Thinly scattered on a finely prepared soil in an ordinary *Pelargonium* box, they may remain until ready for transplanting to a shady spot outdoors, and if a supply of water be given them with an occasional sewage application, the growth will be strengthened and the plants of large size by the time they are required for filling the beds in autumn. The foregoing remarks are quite applicable to *Polyanthuses*, which perhaps will make the bolder display of the two, and are by some preferred in consequence to the Primrose. Both are equally desirable, and each repays for a liberal diet. Primroses from seed sown early and carefully grown will have buds plentifully formed by the autumn, which will continue to open all the winter according as the weather allows; but it is in April and May when they assume their greatest beauty, for then they become a mass of colour in great diversity. *Polyanthuses* do not bloom so early, but this is made up in greater splendour, the spikes rising well above the leaves, forming complete bushes of bloom. These qualities do not appear to be sufficiently recognised, and their claims for spring displays cannot be too strongly urged.

Their removal to make room for the summer occupants of the beds is a great disadvantage to them, happening as it does at a most busy period. They should be replanted immediately, and if possible in a position shaded by lofty walls or trees. In the absence of this, a light covering of strawy material would serve to preserve them from the

FIG. 47.—ONE OF DEAN HERBERT'S HYBRID NARCISSI (see page 321)

scorching rays of the sun. With this attention plants will retain energy sufficient to be of service for bedding two or three years, but even then it is prudent and interesting to raise a fresh stock each or every alternate year. Permanently planted in shrubby borders, by woodland walks, or any such places, they form an agreeable brightness to the general surroundings in the spring.—W. S.

THE BRITISH FRUIT GROWERS' ASSOCIATION.

THE Committee of the British Fruit Growers' Association recently held a meeting in the Horticultural Club Room Hotel Windsor, Victoria Street, S.W., T. F. Rivers, Esq., in the chair. The minutes of the previous meeting were read and signed; a number of new members were also elected. The Hon. Secretary, Mr. Lewis Castle, reported that the Ellesmere meeting and lecture had proved most successful. Mr. Brownlow R. C. Tower, the Secretary of the local Society, wrote to the effect, "You will be glad to hear that we had an excellent meeting here on Saturday night, a very attentive, intelligent audience of gentlemen, farmers, tradesmen, cottagers, &c., filled the Town Hall. Mr. Wright's lecture was much appreciated, as also were the remarks of Mr. Baillie and Mr. Bunyard. At present I think we have done all we can in the way of 'setting the ball rolling' in this district. In the autumn perhaps we may get up some cottage lectures. I am sure we are all much indebted to the Association for the helping hand they have given us all. I doubt not good will result eventually." Mr. Baillie also wrote in similar terms. He said, "A splendid gathering of deeply interested people, and an eagerness and 'go' about the whole thing. Plenty of enthusiasm without exaggeration, and lots of force but no 'fads.'" The Chairman remarked that the result was very satisfactory, and there was ample scope for the work the Association had undertaken to perform in this direction—namely, organising meetings and providing

lectures in country districts. He remarked also that it would be desirable to make it known that all applications should be sent to Mr. L. Castle, Hotham House, Merton, Surrey. Hearty votes of thanks were accorded to Mr. Brownlow Tower for the trouble he had taken in arranging for the meeting, to Mr. J. Wright for his excellent lecture, and to Messrs. Baillie and Bunyard for attending and assisting.

The Secretary also reported that favourable replies had been received from the gentlemen proposed at the previous meeting as Local Secretaries throughout Great Britain and Ireland, and many encouraging suggestions were made showing the deep interest being taken in the work of the Association and the general approval of the programme adopted. Letters were also read from several societies and gentlemen proposing that meetings and lectures shall be held in their districts, which were referred to the Secretary for arrangement. The programmes for the June and August meetings were considered and advanced a stage, and will shortly be ready for publication.

THE WORKSOP ROSE AND HORTICULTURAL SOCIETY.

A SOCIETY has been formed under the presidency of His Grace the Duke of Portland, and with Henry Vessey Machin, Esq., J.P., as vice-President, to encourage the cultivation of Roses and other flowers, fruits and vegetables in Worksop and the surrounding district. It is intended to hold a Show annually in the month of July, when a thoroughly representative collection of the national flower may be looked for—several of the leading growers in the country having promised to exhibit—and when it is hoped to bring together a good display of fruit and other garden produce. The terms of membership are:—For amateurs employing one or more professional gardeners permanently, payment of £1 ls. or upwards. For amateurs cultivating their own gardens or employing occasional labour only, payment of 5s. or upwards. For cottagers, payment of 1s. or upwards. The above subscriptions giving the right to compete for any of the prizes assigned to the members' class, without further payment by way of entrance fee or otherwise, and also giving certain tickets for admission on the show day. Mr. George Baxter is the Hon. Sec.

ROSE LAMARQUE.

It would be difficult to find a better white Rose than this variety for flowering during March and April in the greenhouse. Seldom do we see this old variety cultivated as its merits deserve, when the rapid growth it will make under favourable conditions and the freedom with which it will flower are taken into consideration. In the bud and half-expanded state the blooms are seen at their best, in contrast with the dark green foliage with which this Rose is so well furnished. When the blooms are fully developed the centre of each exposes a faint tinge of yellow in the petals which somewhat spoils its appearance. Lamarque is easily increased from cuttings taken in a half-ripened state with a heel attached about the middle of April. Dibbled into sandy soil, plunging the pots in a gentle bottom heat, the cuttings will quickly make roots, and when growth is established numerous stout sucker-like shoots will burst from the main stems growing from 3 to 6 feet long in one season. From the eyes belonging to stout growths numerous side buds will start and produce from one to five blooms at the points. Such growths as I have described should be encouraged and allowed to grow without check. This variety is not so liable to be pestered with either green fly or mildew as some others, a point in its favour.—E. M.

ROSE CATALOGUE COMMENTARY.

UNDER the impression, I hope an incorrect one, that Mr. Raillem's Rose commentary has come to an end, I write to express my own feeling, and that, I am sure, of many others, of regret that it should be so, and of hope that it will be published separately. Many have been looking for it from week to week with the greatest interest. The criticisms, so far as I could judge, have been most admirable. It will make a little book, which persons beginning to exhibit should make a point of getting, and is full of advice valuable also for old stagers.—A. C.

THE SPARROW PEST.

YOUR correspondent "B.," page 300, asks, Is there any way to keep down sparrows? Yes, there are several ways of doing so—trapping, shooting, and destroying the nests; but to poison them is not advisable. I have no great antipathy to sparrows, as though they are numerous with us I am not able to lay any great damage to their account. They never, as with "B.," trouble our Currants or Strawberries. They were this year for the first time rather hard on my November-sown Peas, but it was because I had neglected to put a few strands of small twine over them, and the weather was harsh at the time, but as I had some ready to transplant I soon made good the damage done. They seldom interfere with my Peas when in bearing. The worst damage they do is to

destroy the flowers of the bedding Primroses and Polyanthus, for which I have to hang up swinging bright coloured pieces of rag—red and blue, &c., and which seem to answer the purpose very well as a scare. In the winter season many persons, as an act of seasonable kindness, feed sparrows with bread crumbs and house refuse, thus keeping them in the vicinity all the year round, and when the house supply stops they pay the gardener a visit, who has to deal with them as best he can. Of course it is always necessary to net small birds.

Your correspondent "W. T.," page 301, under the heading "Birds and Fruit Trees," complains of the numerous sparrows and tomits. I feel sure in many cases both sparrows and tomits are blamed for the mischief done by the bullfinch. Only on Friday last, 11th inst., I was on the look out for bullfinches with a gun in my hand, and came close to some titmice at work in Apple trees, and how daintily they were sorting over the partially expanded trusses of bloom for caterpillars. I saw two or three varieties of them at the same work, but in no case could I see that they had damaged the blossom bud, but I noticed in some cases they pulled out some of the small leaves surrounding the flower truss. Birds of all kinds with us are very numerous, but as I have a liberal supply of netting I only destroy bullfinches, as nearly all the other varieties at some season of the year do good to garden crops.—R. MAHER, Yattendon Court.

YOUR correspondent "B." should get a bird net, commonly used at night, with a lantern at the end of the purse. The body of the net is attached to two long poles, which when open will cover 6 to 8 feet.

FIG. 48.—ONE OF DEAN HERBERT'S HYBRID NARCISSI (see page 321).

Spread this gently over Ivy on walls, hayricks, or thatched buildings or old hovels or sheds with a pigeon hole in, and by moving gently from place to place in the dark he will soon clear himself of the sparrows. I have caught fifty at a draw, taking them out at the end of the purse where the light is attached.—T. H. R.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced House.*—Continue syringing until the fruit commences to soften, as it will during the late stages of ripening, and if syringing is persisted in it will cause the fruit to crack in the skin, and if only slightly it will give the fruit a very unpleasant mouldy flavour. It is very important, therefore, to have the trees quite clean by the time the syringing ceases, as it must when the fruit commences ripening. If there be the least trace of red spider apply an insecticide, repeating it so as to thoroughly free the trees of the pest. It is only the very early varieties, such as Alexander and Early Beatrice, that will be ripening; the others must be well syringed, and have abundant supplies of water with good surface mulchings. Raise the fruits with the apex to the light, shortening or drawing the leaves aside, so as to let the fruit have the full benefit of the sun for colouring.

Second Early Forcing House.—Trees started at the new year are not so advanced as usual, being much retarded by the cold. They are now

stoning, and will need care in preventing checks from sudden fluctuation or depression of temperature, the night temperature being kept steady at 60°, with 5° more on mild nights, whilst on cold nights it may fall to 55° in the morning, 65° by day artificially in dull weather, 70° to 75° on cloudy days, but with clear intervals ventilating from 70°, and freely above 75°. Attend to tying in the growths as they advance, and encourage no more than will be required for future bearing, the extension of the trees, and for the swelling of the current crop. See that there is no lack of moisture in the borders, affording liquid manure if the trees are heavily cropped and not making satisfactory growth, but avoid undue excitement to trees in full vigour, as any impulse given to growth during the stoning is apt to affect the process disastrously. Syringe twice a day so as to keep the foliage clean.

Trees Started in February.—When the fruits are the size of horse beans thin them well, removing the smallest and those on the under side of the shoots, leaving sufficient for the crop, those that are best situated for receiving light and air. Disbudding must not be neglected, and heeling in shoots required for next year's bearing must be carefully done. Syringe twice a day, the second syringing at closing time or early in the afternoon, so as to have the foliage dry before night, increasing the temperature to 55° or 60° at night, 60° to 65° by day, ventilating from the latter, and increasing it with the sun heat to 70° or 75°.

Trees Started in March.—Too many fruits have set in most cases, where they have not it may be traced to over-luxuriance or to immaturity of wood and imperfect development of buds. An over-set is a source of great weakness, and not infrequently causes the incipient fruit to be cast in showers, leaving but a scanty crop. There is no remedy but to well thin the flowers before they expand, not to disbud in quantity but gradually, and to thin the fruits so soon as it can be seen which are most promising by taking the lead. Syringe so as to assist the fruits in throwing off the remains of the blossom, and ventilate freely so as to insure sturdy, short-jointed, thoroughly solidified growth. A temperature of 50° to 55° will be sufficient, not allowing an advance above 65° without free ventilation.

Late Houses.—Attend to fertilising the flowers. There ought not to be anything neglected that is likely to insure the perfect fertilisation of the blossom, as without it the fruit cannot attain perfection. Split stones and disaster in stoning are in a measure due to neglect of attention at flowering. Secure a temperature of 50° by day and ventilate freely, allowing an advance to 65° from sun heat. Leave a little air on constantly. As there is a superabundance of blossom thin it well, first from the under side of the trellis, and where much crowded.

In unheated houses observe 50° as the point for admitting air, and 65° as a maximum from sun heat without full ventilation, but there must not be an advance above it without a full circulation of air. Water must be afforded so as to maintain the soil in a thoroughly moist state, supplying liquid manure to weakly trees. The blossom being abundant should be well thinned.

FIGS.—Earliest Forced Trees in Pots.—Early Violet and Early Prolific, though small, are desirable from affording fruit in advance of the large-fruited varieties. The fruit showing signs of ripening, watering must be gradually reduced, and syringing must cease, but those swelling the fruit should be assisted with liquid manure twice a week, syringing the trees at closing time. A circulation of warm air, rather dry, should be secured when the fruit is ripening. A temperature of 60° to 65° at night, 70° to 75° by day, advancing to 80° or 85° from sun heat, is suitable, closing so as to increase to 90°, but air must be afterwards admitted so as to allow the pent-up moisture to escape and prevent the deposition of moisture on the fruit, which settling on the apex is apt to cause its decay.

Early Forced Planted-out Trees.—Mulching with 2 or 3 inches thickness of short manure is essential to the encouragement of surface roots. This, if kept in a moist state, will be full of active feeders by the time the trees need the most assistance in order to perfect their crops. Trees in borders of limited extent should be well supplied with water or liquid manure as necessary. Syringe twice a day. Ventilate freely in favourable weather, which will secure stout growth and leathery healthy foliage. No fruit is more benefited by the full rays of the sun than the Fig. Any kind of shading, whether by other plants or too much of their own foliage, is injurious and must be strictly guarded against by pinching out the young growths in the late houses and thinning out all the overcrowded shoots. The temperature should be maintained at 60° to 65° at night, 70° to 75° by day, advancing to 80° or 85° from sun heat.

Succession Houses.—Tying-in, thinning, and regulating the terminal shoots must have attention, stopping the spurs at the fourth or fifth leaf, and the laterals from these at the first or second leaf. Mulch the borders with short manure if not already done. Maintain the night temperature at 55° to 60°, 65° by day artificially, 70° to 75° from sun heat, which ought not to be exceeded without full ventilation, as it is very important the growth be stout and the foliage have good substance. When the trees are in full leaf the night temperature should be maintained at 60° to 65°, and 70° by day, allowing it to rise to 80° or 85° from sun heat, closing early with plenty of moisture.

Unheated Houses.—The trees must have attention in pruning, thinning the least fruitful growths and the old and bare, avoiding overcrowding, as it is necessary the growths have abundance of light and air. Allow the shoots for bearing to grow somewhat loosely with their points up to the light. Stopping must play an important part in cool houses. Pinch at the third or fourth joint on the young wood, which

will assist the swelling of the fruit and induce the trees to break and produce short-jointed wood from the base of those in bearing. Ventilate freely at and above 50°, advancing to 65° from sun heat. The border should have a thorough watering if dry, repeating as necessary to bring it into a thoroughly moist state, afterwards mulch with short manure. Figs in unheated houses do not require nearly so much atmospheric moisture as those grown in artificial heat, but an occasional damping will be necessary to maintain a genial condition of the atmosphere.

KITCHEN GARDEN.

KIDNEY BEANS.—A small sowing of both the Dwarf and Runner varieties may now be made. A cold, wet, heavy soil does not suit them at this season. The seed will perish in such, and must therefore be sown in somewhat light material. A sunny position is also advantageous. The earliest and most prolific crop of Dwarf Beans we are able to secure is supplied from seed sown on the ridges between Celery trenches. The elevated position seems to suit them better than any other, but in cold backward districts they may be sown at the foot of a south wall. In very cold localities the seed may be sown under frames, but in the ground to produce a first crop.

SAVOYS.—It is a common mistake to sow Savoy seed too early. When the plants heart in September they are far past their best by December, and that is the proper season for Savoys to be gaining their prime. Growers have the choice of three types—the large or Drumhead, the Globe or medium, and the Tom Thumb class. The Globe is the most desirable as a main crop. The heads are very firm, an important point, and their quality is good. The present, or from now until the first week in May, is a suitable time to sow the seed. It is often sown too thickly; crowding of the plants at first, or at any time, is an evil to be avoided.

LATE POTATOES.—Potato planting should be finished as soon as possible; compact growing varieties are best for gardens. Large tubers may be cut into two or more pieces, but unless in the case of choice and scarce varieties do not attempt to reduce them to a single eye. The ground should be moderately rich and dry at planting time. Artificial manures do not produce heavier crops or finer quality than farmyard manure, but the former is less disposed to force a large top growth. To use a large quantity of both is extravagant.

BEETROOT.—This is another crop of a somewhat tender nature. Seed should not be sown until after the middle of April. Large roots should be avoided. A perfect Beet can be spanned with the hand, and no attempt should be made to have them larger. Do not therefore sow in very rich soil, but let it be free and open and void of long manure. Sow in rows 1 foot to 15 inches apart, and in drills 3 inches deep.

LETTUCES.—To have Lettuces in the best condition, sow sufficient seed once a fortnight to give a supply that will meet the demand for a period of about that length. This fortnightly sowing should be begun at once. Lettuce raised in frames and under protection may be planted in the open ground. Our best Lettuce are invariably produced on the ridges between the Celery trenches. They gain a size there without any further attention after planting. We frequently make our Celery trenches in advance of the time they are wanted to secure ridges for Lettuce.

EARLY CELERY.—Plants in boxes and frames are rather too tender to plant out before the 1st of May, but they should be gradually hardened with the view of having them ready by that time. Do not on any account allow them to suffer by want of water. Give them liquid manure if they are backward.

THINNING VEGETABLES.—Parsnips, Carrots, &c., will soon require this attention. Begin as soon as they can be handled, but only thin them to 1 or 2 inches apart the first time. This will insure sturdy growth, and they can be thinned more later on as they require space, but it is harmful to neglect them at first. After thinning, run the Dutch hoe rather deeply between the rows to loosen the ground, that the rain may penetrate freely and not run off the surface.

HERBS.—Mint is now plentiful in the open. Do not hesitate to cut it freely, as this will induce the stem that remains to branch out into numerous shoots. Sage and Thyme are readily raised from seed, and may be sown forthwith. The seeds are small and must have a fine soil on the surface. This applies especially to Thyme. Fork and manure the ground well. A small bed will be sufficient, as the seedlings should be transplanted the second year, and may be grown closely the first. Sweet Basil is frequently in demand. It requires to be sown and grown under glass, but a pinch of seed may be sown in a 6-inch pot, and the plants transferred to a frame or boxes when 2 or 3 inches high.

MISCELLANEOUS.—Earth up recently planted Cauliflowers; draw the soil well to the collars. Peas and Broad Beans may be treated in the same way. Stake Peas before they fall over. Do not put tall stakes to dwarf varieties. Pot Vegetable Marrows and ridge Cucumbers singly in 4-inch or 5-inch pots. Give them treatment that will cause them to be strong, healthy plants by the middle of May. Pot Capsicums in rich material. Keep them in a warm atmosphere, and syringe them frequently.

PLANT HOUSES.

Gardenias.—Where bushy plants with three or more flowers are appreciated for decoration, insert strong cuttings singly in small pots at once. Cuttings of soft wood root quickly if shaded from the sun and kept moist in brisk heat in the propagating frame. Young stock

in from 3 to 5-inch pots may be placed into larger pots as they require more root room. Old plants that have flowered and are rather straggling may be well cut in and started again into growth in brisk heat. If these plants are infested with mealy bug or scale clean them thoroughly, and then give gentle bottom heat to push them into growth. Gardenias do well in a mixture of loam and peat in equal proportions with the addition of sand; leaf mould may be substituted for the peat. They will do equally satisfactorily in good fibry loam, one-seventh of manure and sand. Water carefully until the roots are working freely. The syringe may be used twice daily.

Eucharis.—Plants that have been potted should be watered with care. If the pots are plunged little water will be needed until the roots are forming freely if the foliage is well syringed two or three times daily. Maintain a moist atmosphere about the plants, and shade them from bright sunshine. They soon recover from the potting if they are carefully treated in this respect. Make up a few pots of the young bulbs for the purpose of superseding old ones that become exhausted. To keep a healthy stock of plants over a lengthened period of time it is a mistake to retain only strong flowering bulbs.

Medinilla magnifica.—This may now be placed in a shady part of the stove to make its growth. It advances rapidly in heat and moisture, and soon attains a sufficiently large size to be very striking when well flowered. Its long racemes of pink flowers are highly attractive. This plant does well in a compost of fibry loam, one-seventh of manure, and sand. It is very liable to mealy bug and thrips; both soon injure its foliage if allowed to become established upon the plant. It is difficult to eradicate the former without injury to the leaves near their axils. The thrips can be kept in check by fumigations with tobacco smoke and a liberal use of the syringe. During the season of growth liberal supplies of water are necessary.

Tydas.—Such varieties as Madame Heine that are evergreen and do not make underground stems will have produced plenty of cuttings, which should be rooted in pans. These strike freely in the propagating frame in sandy soil. The cuttings may be allowed to grow together in the pans until they have attained strength, when the heads may be taken off and rooted singly in small pots. These will be early enough for next season's flowering. The old plants can be thrown away as well as those in the pans afterwards. If good sized plants are needed in preference to a quantity in 8-inch pots the cuttings inserted now may be placed singly in small pots and grown on. The shoots should be pinched from time to time to induce them to branch.

Acalyphas.—The heads of plants that have grown tall may be taken off and rooted in small pots. They root freely in the propagating frame. Directly they are well rooted carefully harden and grow them in an intermediate temperature. In brisk heat they soon run up tall and do not colour well. If good heads are rooted and the plants placed in 5-inch pots the lower leaves will droop gracefully, and colour beautifully if exposed to the sun. During the summer months a few plants are handsome in the conservatory. To increase the stock the old plants should be retained, for they will soon produce side shoots in heat.

Cyanophyllum magnificum.—When well grown this is a beautiful foliage plant, and where stove foliage plants are appreciated it should find a place however limited the collection. To do it well liberal root room is necessary in a young state. It should never be allowed to suffer by the want of root room until it has been placed into 10-inch pots, which are large enough to grow excellent plants in with large bold foliage. It delights in heat and moisture and a shady position. Young plants should be potted on in a compost of fibry peat and loam in equal proportions with the addition of sand and charcoal. It grows well in any light open compost, and leaf mould may be substituted for the peat. While growing liberal supplies of water are necessary, in fact at no season of the year should the soil about the roots become dry. Plants that have grown too tall may have the lead removed to induce it to make side shoots. When these are large enough they may be taken off and rooted singly in small pots. They strike freely in sphagnum moss and sand in the propagating frame. They must be well shaded from the sun, and most carefully exposed to light and air after they are rooted. The under side of the leaves should be syringed freely to keep down thrips. If sponging has to be resorted to the foliage is soon damaged. *Sphaerogyne latifolia* requires similar treatment, and will succeed in a slightly heavier soil.

were provided with in autumn, the form of the hives and their coverings, and last, but not least, the weather so favourable for breeding and airing themselves without loss. The promoters of brood-spreading have fairly lost their case, and the beginner should note this and learn that although "the hand of the diligent maketh rich," and we must learn to be wise as well as diligent.

SWARMING.

Every year is adding more gardeners to the list of bee-keepers, and I believe the time is not far distant when it will be the rule and not the exception to see bees kept in every garden. One objection some have to keeping bees is their liability to swarm without being observed, to the chagrin and loss of the bee-keeper. It is a mistaken idea to suppose bees can be prevented swarming. All the phases of swarming and its prevention have been treated before. It is sufficient for the present article to say that bees will swarm from half full, two-thirds full, and more or less full hives, in spite of all the ekes that can be placed on or under them. I use every means to prevent swarming before the hives are crowded, but I am not able, nor ever will be able, at times to prevent it. During the honey gathering and swarming season bees should not be left without keeping a watch over them, at least between the hours of 8 A.M. and 4 P.M. If left to themselves bee-keepers must take the consequence of all losses.

I prefer natural to artificial swarming, but cannot advise every one to adopt the same course. I have advantages of closely attending my bees that others have not, and those I do advise to to practise artificial swarming rather than run the risk of losing swarms, consequently all profit. The divisional hive, as it is in other respects, is superior for artificial swarming also.

The only caution necessary is not to attempt it before the hive is in a fit condition. Choose a fine day when the bees are at work, uncover the hive, and remove the slides after the top bars have had a slight rubbing with carbolic acid, then insert the carbolicised paper between each comb, no paper to be broader than will barely reach the bottom of two boxes, and have a pin or obstruction near the upper edge to prevent it dropping to the bottom box. The only use of the carbolicised paper in this case is to ensure the queen being in the under box. Now detach the two uppermost from the lower one, place the last upon one or more foundationed divisions, meanwhile withdrawing the papers from the first, and let it stand a short time to collect as many bees as will attend to the brood and raise royal cells. Immediately this is done remove it to a distance and place the portion with the queen and original stand on the old site. When combs are simply lifted from one hive to another that has not the odour of their own hive the bees do not take to it so kindly, and this is much, if not all, in making artificial swarms, and therein lies success.

It is generally the third or fourth week of June before supers can be placed on hives with anything like certainty of getting them filled quickly and without interruption, and finished in a manner that they may be presentable to the most fastidious. Now that our hives are so far advanced it would be extreme folly to attempt to delay or prevent swarming. Early swarming gives us three instead of only one honey gathering hive, and sufficient queens to supersede those that have laid since January, and for the next year. Young and fertile queens is the key to successful bee-keeping if appliances are in accordance with what the nature of the bee and skilful management demand.—A LANARKSHIRE BEE-KEEPER.

THE BEE-KEEPER.

NOTES ON BEES.

Up to the 5th April the bees have had six days' work without interruption, and gathered honey from the fruit blossoms, and are in many cases in a fit state for it, and for swarming. Never in any season have I seen them so far advanced, a marked contrast to the same time in 1889.

That bees are so well conditioned without either brood-spreading or stimulative feeding is entirely due to the abundant stores they

TRADE CATALOGUES RECEIVED.

Bruant, Poitiers, Vienne, France.—*General Catalogue*.

Merryweather & Sons, 63, Long Acre, W.C.—*Catalogue of Fire Engines and Hydraulic Machinery, Hose, Fittings, &c. (illustrated)*.

Ellwanger & Barry, Mount Hope Nurseries, Rochester, New York.—*General Catalogue*.

Thomas Painter, Smallwood, near Scholar Green, Stoke-on-Trent.—*Catalogue of Dahlia Plants*.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Back Numbers (J. E. F.).—We know of no more likely way of your obtaining a purchaser than by advertising, or making your desire known at gardeners' meetings if there are any in your district.

Figs (F. Cantab.).—The White Marseilles is the earliest you name. There is no material difference in the time of ripening of the others. For market purposes we should rely mainly on the Brown Turkey.

Primroses and Polyanthus (E. Wollen).—The flowers you have sent are highly attractive, and may be described as good border varieties well grown, a credit to the seedsman and cultivator.

Horticultural Shows (F. Callender).—No complete lists of flower and fruit shows to be held in Great Britain are published for sale. Most of the leading shows are advertised periodically, and lists of special shows are published occasionally in this Journal. You would perhaps see the dates of Rose shows on page 298 last week.

Cropping Vines (Anxious).—You may as well ask us what weight a horse will draw up a hill without indicating the age or condition of the animal, or the character of the incline, as expect us to answer your question satisfactorily. If you will state the age of the Vines, the strength of the laterals, the size and texture of the leaves when developed, and the length of the rafters we shall have data whereon to base a reply.

Agathaea coelestis (C. W., Wales).—The above is the name of the blue flower you have sent, and is fancifully known as the Blue Marguerite. It grows and flowers freely in loamy soil in a very light position in a greenhouse, also when planted out in good soil in an open position in the garden at the same time that Heliotropes and other tender plants are "bedded out." Cuttings of the young shoots strike readily in moist sandy soil in a close heated frame, or under a bellglass in a warm greenhouse.

Glonera jasminiflora (Idem).—This plant, which is also known as Psychotria jasminiflora, is a member of the large family Rubiaceae, and is a native of Brazil. It requires to be grown in an open soil of peat and loam and needs a stove temperature. It will, however, succeed in any moderately warm house during the summer months.

Pegging Down Roses (Inquirer).—If the plants have been established for at least a year where they are growing the long shoots may be "pinned down," as you propose, and the weaker cut back if you desire the greatest number of flowers for decorative purposes, and not a limited number of exhibition blooms; but if the Roses have only been recently planted, or last autumn, it would be very inadvisable to retain the long shoots, and it would be better to cut them back somewhat severely, the young growths notwithstanding.

House Sewage for Strawberries (F. J.).—The liquid which you describe as principally kitchen slops, including we presume soap-suds, may be applied without dilution to Strawberries that need assistance, though it might make strong young plants in rich soil grow too luxuriantly, producing a finer crop of foliage than fruit. It may also be given to fruit trees that do not make sufficient growth and the soil is well drained naturally or artificially.

Superphosphate of Lime for Fruit Trees (Idem).—You ask "if a good superphosphate is as good a manure as can be used, or if we know of a better mixture for a fruit garden?" We have often published what we consider better mixtures for the purpose, but if your land contains a sufficiency of potash the superphosphate may answer your purpose, as it will supply lime with phosphoric and sulphuric acids, and these are what fruit trees and most crops require, but most of them require potash also, and some must have it or they will not thrive. It can be applied in the form of kainit, which is the cheapest form, or saltpetre, which is the dearest, but the most active, as it also contains nitrogen.

Seedling Briars (A. W.).—Where the buds have "taken" the Briar stems may be shortened, say to a foot, and all the buds picked out of them; the Rose growths can then be secured to the stems, otherwise they might be broken by the wind. You can cut the stems down to the buds if you prefer to insert sticks for supporting the growths. We have often inserted dormant buds at this season of the year, and they have

grown satisfactorily; if they fail others of this year's growth are inserted as soon as ready.

Tomatoes Diseased (H. E.).—Wednesday morning's letters cannot be fully answered in the current issue. You do not say whether the fruit or leaves are attacked. Keep the house drier and freely ventilated, and apply sulphur, sulphide of potassium, Fowler's or Ewing's mildew composition, as may be most readily obtainable. Your other question cannot be answered this week.

Lily of the Valley Failing (Dutchly).—Failures similar to yours are not uncommon when Dutch crowns have been relied on for early forcing. The variety is evidently not suitable for the purpose. We do not suggest there are no varieties grown in Holland that will not force, but it is well known that, as a rule, Dutch are inferior to Berlin crowns, also to many grown in England, for the production of early flowers with the aid of brisk artificial heat. The samples you have sent are probably the result of weak immature crowns, for strong and good examples usually flower very well at this season of the year.

Scale on Peaches—Cutting down Clematis (Inquirer).—The trees and house ought to have been much more thoroughly cleansed with something in addition to the solution of soft soap. Methylated spirit will destroy scale, but we must leave the best method of application for you to determine after applying a little to infested parts and noting its effect. The Clematis will grow freely if cut down after flowering, but there is no certainty that the growths will produce flowers next year. They must be thinly trained in order that they may ripen under the full influence of sun.

Nitrate of Soda for Apple Trees—Prunuses for Pots (J. M.).—Nitrate of soda alone is a very incomplete manure for Apple trees. It is certainly a growth stimulant, and we can quite conceive of its doing more harm than good to some trees. If you wish to try it in solution half an ounce to each gallon of water will suffice. We cannot tell you how often to apply it, nor can anyone usefully without knowing the condition of the trees. We have several to which we should not apply any if we had the salts as a gift. Two of the best Prunuses for flowering in pots are *P. sinensis flore-pleno* (double) and *P. pissardi*. This was illustrated in the *Journal of Horticulture* a fortnight ago.

Fine Double-spathed Richardia (A. MacKenzie).—We have had many specimens of the same character as yours, and some very fine, but we think yours is the premier. The largest spathe is 1 foot long and 6½ inches wide, the other 9 inches long, both measured from the base of the spadix. The length of the largest leaf measured from the tip to the point of the lobe is 19 inches; width below the leafstalk 10 inches; colour, deep green; texture, very stout, and the whole character of the specimen is indicative of superior cultivation. Perhaps you may not object to describe your method of growing Arums so well for the benefit of readers who desire to excel in their culture.

Cockroaches (J. W. W.).—They are the largest of our native cockroaches, the *Blatta germanica*. Professor Westwood, however, has great doubts whether this is truly indigenous. It is very abundant in Germany, and occurs also at the Antipodes. It is not a very common species, seldom occurring in houses, but being found in fields amongst heaps of rubbish, dead leaves, &c., sometimes in hollow trees. We have never heard or read of an instance of its having done any mischief to cultivated plants; still, if introduced to a garden it might soon increase and become troublesome, if circumstances were in its favour. For, as was pointed out some years ago in this Journal, the familiar *B. orientalis* sometimes quits the kitchen and makes excursions to gardens and frames where, owing to its nocturnal habits, it may do mischief frequently and escape detection.

Tuberose—Alocasia (J. G.).—You may treat Tuberose now practically the same as you would Hyacinths in the autumn, potting the bulbs and burying the pots in cocoanut fibre refuse till roots form and growth commences. They start the sooner with gentle bottom heat, and the plants grow admirably with the pots plunged in a warm damp medium, such as leaves, mainly, in frames in summer. If the pots are not plunged they should be stood on a moist base, not on a dry open lattice stage over hot-water pipes, or the leaves will become infested by red spider. For free growth they require a temperature from 60° to 80°, or more, with adequate moisture, full light, and a free circulation of air. Perhaps you had better wash all the soil from your Alocasia and pot in a fluffy mixture of fibrous peat sphagnum and plenty of crushed charcoal, plunging the pot in a hotbed in a frame or pit with a moist atmosphere, shading the plant from the sun. Readers have no occasion to apologise for seeking information; we exist to impart all we can.

Salad Plants (H. R. W.).—We have received the French seed packets and samples of seed. "*Cerfeuil commun*" is the common or plain-leaved Chervil, *Anthriscus cerifolium*. For ensuring a supply throughout the season seed may be sown on the south side of a wall in August, and the plants will stand the winter for spring use. Sow again now, both in an open sunny position and a cool shady place. A few leaves are used in salads and for culinary purposes when their flavour is desired. There is a curled leaved, also a turnip-rooted variety, the roots of the latter being used in a cooked state. "*Pourpier à salade*" is the common Purslane, *Portulaca oleracea*. It is an annual, and seeds are sown at intervals from April to August. For early spring use in salads plants are raised under glass. The soft stems and leaves are largely used in a cooked state in Holland. "*Pimpernelle petite*" is the common Burnet, *Poterium sanguisorba*. It is a hardy perennial, raised from seeds sown in the open ground now or in August. The plants are cut frequently for affording a supply of fresh green leaves for salads, to

which they impart somewhat of a Cucumber flavour. We note what you say on the other matter and have not the slightest desire to induce you to move in it. We are pleased to give what information we can on gardening subjects.

Eucharises Scorched (*H. W. G.*).—You are doing right by affording light shade from bright sun to prevent the scorching of the foliage. Some plants are more liable to injury than others by the sun. This depends on the condition of the plants, their rooting power, the support afforded, and the texture of the leaves; also the position occupied, and on the quality of the glass. We cannot say whether you would have done better by admitting more air and thus keeping down the temperature, because we have no idea of the temperature that has been maintained and the method of ventilation adopted. We know it is erroneous practice to permit a house to get excessively hot and then throw open the ventilators for bringing down the heat with a rush. That is conducive to scorching. You cannot do better than allow the plants to have as much sun as they appear to enjoy and not afford needlessly dense shade. Thousands of plants grow and flower well under constant light shade such as those to which you refer at Chilwell, and you are right in your supposition that those in charge of Mr. Pettigrew at Cardiff have more sun, but he would not allow the foliage to be scorched by refusing to afford shade when it would be beneficial to the plants. If you produce thick deep green leaves on plants which crowd their pots with roots you need have no fear of their not flowering.

Tuberous Begonias (*J. W. S.*).—Thousands of Begonia plants raised from seed soon a month or two ago we expect to see flowering beautifully this season, both in pots and planted out in flower beds. You are either not an expert cultivator or have not the requisite conveniences for growing the plants. Grown well, under suitable conditions, the plants cannot help flowering the first season. Stout short-jointed cuttings, neither too soft nor too firm, strike readily in a mixture of sand and leaf soil or cocoanut fibre refuse, with the pots plunged in a gentle hotbed of 80° or 85°, in a frame or other suitable place having a temperature of 60° or 65°, not overwatering, yet affording adequate moisture. Daily sprinklings are fatal to success if the soil is dry below. Cuttings strike freely in the summer inserted in light soil under handlights in a shaded position in the garden, indeed many are struck without the aid of glass. If correspondents who fail in anything were to briefly describe their procedure and cultural conveniences we could probably indicate the cause of failure. The less the plants are shaded the better, a little tiffany usually sufficing. In some houses they grow fairly well under light permanent shade, such as that from summer cloud. The most luxuriant and floriferous plants in open-air beds are not artificially shaded, but have abundance of roots working freely in rich moist soil. The more plants of various kinds are shaded the more shade they need, and many are weakened accordingly.

Diseased Damson Trees (*J. H.*).—We are unable to detect any insect, but the epidermis has been punctured by some insect or shot. The cause of the exudation is a fungus, named by Professor Oudemans *Coryneum Beijerinckii*, the mycelium of which develops a ferment, penetrating the cells, whereby tissue is formed with new properties. The serous matter in contact with the air is attacked according to Pasteur by a new series of organisms—aerobes, and these by others in succession, until the ultimate products are oxidised—the carbon, hydrogen, and nitrogen of the organic matter being transformed by the oxygen of the air into the inorganic elements. These dried or oxidised particles are gum; the white matter deposited around the edges of the wound is composed of carbonates of potash and lime, with a trace of magnesia. The disease is known as gumming, and particularly attacks species or varieties of the genus *Prunus*. The fungus is the exciting cause. There must be laceration or openings by which the germ tubes enter, and these may be effected by insects, which may also carry the spores. The best remedy is stamping out—the removal and burning of the infected parts, and the removal from the neighbourhood of Sloe bushes and wild Cherries. The common Laurel is also infected with this same fungus. Over-luxuriance in the trees has a tendency to induce the disease, but it may be aggravated by its opposite, viz., a deficiency of support, whereby the sap becomes morbid and the morbid matter is ejected by agency of the ferment. Perhaps this lack of energy is due to a deficiency of phosphorus or phosphoric acid. In this case superphosphate of lime is decidedly beneficial. Lifting and root-pruning are well-known means of preventing gumming when it proceeds from over-luxuriance, and applying phosphatic in place of nitrogenous manures. Paradoxical as it may seem, lifting and replanting is also the best remedy when the trees are weakly and infected with gum, because the fresh compost given causes an increase of the roots, thereby affording the trees more and better food. In this latter case, whilst there is an increase of nitrogenous matter, if decayed fibre is used, or manure, the change will only be temporary unless lime is applied, preferably in the shape of superphosphate, so as to be at once available, and there must be a corresponding addition of potash; 3 to 5 cwt. of superphosphate with half the quantity of muriate of potash per acre would go a long way towards ridding fruit trees of gum and canker. When the surface soil is deprived of what fruit trees need, including moisture, the roots descend into the subsoil, and as they cannot find the requisites of health there disease ensues and finds expression in the form of gum and canker.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes.

Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*J. P. K.*).—The flowers were scarcely recognisable, as, besides being old, they were loosely packed and were consequently much bruised in transit. Perhaps it is a small example of *Dendrobium barbatulum*. (*S. B.*).—1, *Azalea linearis*. 2, *Acacia Drummondii*. 3, *Narcissus cyclamineus*. (*W. T.*).—1, *Oncidium concolor*. 2, *Laelia einaebarina*. 3, *Cattleya Trianae*. 4, *Oulotoglossum Rossi*. (*M. M.*).—1, *Adiantum Williamsi*. 2, *Asplenium cicutarium*. (*Wm. H.*).—1, *Cytisus purpureus*. 2, *Calceolaria violacea*. 3, *Polypodium pectinatum*. (*Hills*).—Yes, it is *Allium neapolitanum*, and is sent into Covent Garden Market in large quantities. (*A. E.*).—It seems to be an ordinary form of *Lilium candidum*.

COVENT GARDEN MARKET.—APRIL 16TH.

A SLIGHT improvement in business this week and all goods have been more readily cleared, but not till prices have tempted buyers.

Bedding Plants in variety, in boxes and pots.

THOUSAND-HEADED KALE.

From the present time onwards through May, June, and July this most useful crop may be drilled in accordance with the purpose

it is intended to serve. Drilled at once it is ready for use in August either for sheep, cows, or store cattle. The May sowings come into use in October, and are available till the end of the year, and those of June or July follow for early or late spring food. Thus much may be stated generally, but it should not be forgotten that the April sowings often give a supply of most valuable green food from autumn till late in spring. The weight per acre may or may not be equal to that of Drumhead Cabbages, but under high cultivation it comes very near it, and the Kale has the valuable property of an abundant second growth from stalks which are just so many naked stumps after the first foldings by sheep or cuttings for cattle.

The crop is a valuable one; both flock masters and dairy farmers regard it as specially *the* crop at certain seasons of the year, as being indispensable for their requirements, and success with it depends upon cultivation and management quite as much as with any other crop. It can serve no useful purpose to lay stress upon the loss of Kale in very severe weather, for such a loss may and does happen with roots occasionally, and the fact of its having proved generally a profitable and reliable crop is sufficient for our purpose. Soil is comparatively unimportant, but cultivation is most important, and just according to the condition and fertility of the soil will be the crop of Kale produced in it. Therefore be liberal both of labour and manure—giving as much so as if for a root crop—for depend upon it the results of “fair” to “very heavy” are governed by this, and when the soil is low in fertility we always use the double-breasted plough, placing all the farmyard manure in the furrows and drilling chemical manures with the seed. The plants then have plenty of sustenance as well as depth of soil and a fine tilth, all tending to quick germination, speedy and robust growth, and heavy bulk of crop.

The manner of the clearance of the crop depends upon that which is to follow, and as we generally take a corn crop after Kale the stalks we got up with the roots on—not chopped off—as soon as a fold is finished, and they are chopped up, spread over the surface and ploughed in. If this is done fold by fold it becomes just as much a matter of course as root slicing for the sheep, and instead of being regarded as a nuisance to be got rid of the stalks thus turned to account are really valuable as a fertiliser.

For folding with hoggets towards the end of the year we especially favour a mixed crop consisting of alternate strips or “lands” of Swedes and Kale. This plan had its origin in the success resultant from filling up vacancies among Swedes with Kale, the mixed feed being especially liked by the sheep, and subsequently the Kale lands always afford a supply of plants for filling up blank spaces among the Swedes. For certainty both in cropping and hardiness we have found Kale altogether preferable to Swedes, and it is certainly very wholesome nutritious food. Another advantage not to be overlooked is the fact of the stems being available for a second growth even when cut off for cows close to the ground when other food is scarce, and in a backward spring this second growth is of especial value. This fact alone ought to obtain a place for Kale upon every farm, and it is clearly to a farmer's interest to curtail the space usually devoted exclusively to root culture and to devote part of it to Kale culture, which with plenty of silage would enable us to become far more independent of adverse seasons and weather than hitherto.

Autumn Giant Cauliflower. It was in the neighbourhood of Swanley that we first saw sheep folded upon this crop, and it was a veritable “eye-opener.” Not upon the dainty “flower” itself were the sheep regaled, for that had been cut from every stalk and sent to market, but upon the leaves left to grow to a large size upon the stems, and thus afford a lot of tender wholesome food for the flock, and ensure a thorough enrichment of the soil from the folding. Now this profitable crop need not be long upon the land, and if spring sown plants are raised in a seed bed they may be transplanted to land where sheep have been folded upon Rye or Winter Tares, and so be cleared off in time for early autumn

cultivation and a third crop. If this is termed sharp practice it is sound enough, and it is based upon the principle of the soil being a storehouse of plant food, which we have only to keep well and regularly supplied in order for it to answer promptly all our demands and requirements.

WORK ON THE HOME FARM.

Since our last note was written especial attention has been given to the value of corn drills, which are also available for corn hoeing, at a meeting of the Farmers' Club. As mention was made there of the steerage hoe, it may be as well to explain for the benefit of those not having a steerage drill hoe, that there is a simple and comparatively cheap form of corn hoe to be had, the steerage or guidance of which is managed by means of handles behind the hoes. It was claimed for steerage hoes that they are the most efficient destroyers of Charlock, and we may concede that they are a means to so desirable an end, and they are nothing more. Charlock comes as thickly among the corn in the rows as it does between the rows, and no hoes can touch the pest there. No quarter must be given to Charlock whenever it makes its first appearance, for it is precisely because it was not stamped out at first that it has spread far and wide through the land, and once it is established upon a farm the process of eradication is simply ruinous. In its primal condition of one of our native wild plants it is comparatively inconspicuous, but once it finds its way to cultivated land it soon gets beyond control, and yet if it could only be kept within bounds and well under control it would be useful enough. It is the wild Mustard (*Sinapis arvensis*), and we can very well dispense with it altogether, for the White Mustard (*S. alba*) of commerce answers all our requirements.

Corn sowing even on clay farms is now done, and we much fear there will again be many inferior fields of Barley, as so much of it was sown late in the season. The second and third weeks in March are considered the best two weeks of the whole year for sowing Barley in East Anglia, and the weather was so unfavourable then that it is certain none was sown on heavy land. Glad are we to say more and more attention is gradually being given to Oat culture; and without at all regarding Oats as a panacea for hard times, it is certain that by means of better culture they may become much more profitable than heretofore. Of other sowing now claiming prompt attention there are Mangolds, Swedes, Cabbage, Kale, Tares, mixed seeds for layers and permanent pasture, Carrots, Kohl Rabi, and White Mustard. As foul land is cleared of weeds Mustard is sown either for folding or to be ploughed in, and if the season proves favourable a second sowing will follow, our aim being to render the land fertile as well as clean for another season.

OUR LETTER BOX.

Turkey III (W. S.).—The swollen head looks like the effect of a cold, but as you give us no particulars as to age, feeding, &c., we cannot say for certain. Send full particulars to our contemporary *Poultry*, and in the meantime remove him from the hens, keep him in a warm house, feeding on soft nourishing food sprinkled with ginger. Give him 5 drops of camphorated oil in a teaspoonful of glycerine night and morning, and sponge the swollen parts frequently with warm water. A good plan is to hold the bird's head over the steam made by pouring boiling water on a few hops. If there is an offensive smelling discharge from the nostrils and mouth he has roup, and you should at once get No. 337 of *Poultry*, where the complaint is fully dealt with. It can be had post free from this office for 1½d.

REMARKS.

- 6th.—Generally cloudy in the morning; occasional slight showers in the afternoon.
7th.—Dull and rainy till noon, then fine and generally bright, excepting a shower at 6 P.M.; showers again at night.
8th.—Cloud and sunshine, with high wind, till 11 A.M., then heavy shower of soft hail (apparently fragments of spheres about ¼ in. diameter), lasting five minutes (thunder at 0.50 p.m. (three peals) and more soft hail, some nearly ½ in. in greatest diameter; heavy rain from 5 P.M. to 7 P.M., then fine again.
9th.—Fine and generally bright.
10th.—Dull and drizzly morning; showers in early afternoon; fine and bright for an hour or so before sunset.
11th.—Bright and fine throughout.
12th.—Bright and fine throughout.
On the whole a fine week, noticeable chiefly for the sharp radiation frosts on the last two days.—G. J. SYMONS.

PARIS GREEN AND CATERPILLARS.

IN your issue of the 30th January last you did excellent service to fruit growers by giving engravings of branches taken from some of my fruit trees sent to you by my gardener, Mr. S. T. Wright. Fig. 17, c (page 95), showed within a radius of about a quarter of an inch a deposit of no less than 152 winter moth eggs. The total loss of my fruit crop of last year caused by these pests, and in addition the wholesale destruction of this year's Pear buds, naturally decided me to do my utmost to get rid of the devastator. A serious task it has been, and only very partially successful. The number of trees is about 6000. Three men were occupied six weeks in cutting off the ends of branches, and I am afraid to say how many millions of eggs we have burned. By keeping branches in my early Peach house, and watching them daily, I made the unpleasant discovery that the hatching period is spread over seven weeks. Out of doors it seems to be shorter. I have also been experimenting on branches dipped in sundry substances and liquids with a view of destroying the eggs by either sealing them in the interstices, which can be done with white lead, or burning them with vitriol, &c., which cannot be depended upon.

Then came the difficult question, What is to be done? I have been in correspondence with Miss E. A. Ormerod, whose kindness and energy are unending. She very kindly sent me her report for 1889, and that decided me to try Paris green. Up to the present time we have been aiming at compassing the death of our insect enemies by direct action on their bodies, now we have to arrive at the result indirectly by poisoning their food. Let me at this stage caution all fruit growers, whether masters or gardeners, against accepting anything I may write, but to make experiments for themselves. Miss Ormerod informs us in the report above named that the manufacturers of Paris green are Messrs. Blundell, Spence & Co., Limited, of Hull, and 9, Upper Thames Street, London. These gentlemen sent me a supply, and have kindly informed me that Paris green has been in use for many years in the United States as an insecticide.

Our earliest discovery of caterpillars was made on the 27th March, the season being then three weeks earlier than 1889, and consequently there was plenty of food ready for them. I was caught napping I am afraid—lulled into a sense of security by the enormous destruction of eggs. My magnifying glass soon brought a rude awakening. Here let me say that any opinion expressed by anyone not using a magnifying glass is utterly valueless. The caterpillars in the early stages are so small that very few eyes can detect their existence. When leaves are not to be had they do equally well on buds, and a very few days suffice for the destruction of fruit prospects. I first made tests in order to arrive at a safe strength at which to apply the liquid without damaging the foliage, and found that some little damage was done to the leaves, but not to the buds, from an application of 1 oz. of Paris green to four gallons of water. Messrs. Blundell write, "Paris green should be mixed with water—say 1 lb. to 200 gallons water, and never stronger than 1 lb. to 120 gallons water. The application should be in the form of fine spray by means of a force pump. The foliage need not be drenched, but the spray should be allowed to fall upon the trees until it begins to drop from the leaves. Dry weather should, if possible, be chosen for the application. The Paris green is a fine

crystal, insoluble in water. It should be kept in suspension during use by being well stirred. As Paris green is poisonous be careful in the use of it, especially in the dry state, and avoid breathing the poison which is given off when the colour is handled." These gentlemen are now laying themselves out to supply the demand which is springing up, and have just sent me a circular with all needful information, which doubtless they will forward to anyone interested.

After my experience as above I adopted as a simple and easily remembered formula 2 ozs. of Paris green to 20 gallons of water; but think it would be prudent after the first spraying to reduce to 2 ozs. to 25 gallons. Owing to unavoidable delay I could not commence spraying until the 11th inst. I much regret this, for it is evident from what I have written above that all trees should be sprayed before the first caterpillar is hatched. The delay has caused me serious damage. On examining the sprayed trees on the morning of the 12th I found quantities of dead caterpillars and aphides. Bearing in mind the fact that the eggs are hatching during a period of some weeks, and also that it was desirable to ascertain whether repeated spraying would injure the trees, I had one row of Mother Apple sprayed for the second time that day (12th), and the result being more deaths and no apparent damage to the foliage, we sprayed on the 14th and again on the 17th. At the present date (19th) I can report favourably all round. So long, however, as the caterpillar appears we must spray.

The bitterly cold weather is against us, as it prevents the opening of the buds, and the liquid cannot easily find its way into the folded leaves where the insect is eating away at its ease. I am afraid no more can be done this season, but not a moment should be lost. I take a very gloomy view of fruit prospects in all districts infested with caterpillars last year. Pears, Apples, and Plums are alike affected, and the worst of it is that the apathy or want of knowledge on the part of the enormous majority of fruit growers has led them to neglect all remedies. I can only say that in spite of great vigilance, and after the adoption of all sorts of preventive measures, I shall regard myself as very fortunate if I can save a fair crop of Apples and Plums, and this under more favourable conditions of soil, climate, and culture than fall to the lot of most growers.

One word as to spraying. All gardeuers up to their work can of course spray, but Mr. S. H. Stott of Fulwood, near Preston, has patented a small brass sprayer, which will do good service where skilled labour is not available. The strawsoniser is a perfect sprayer, and has been remodelled, but owing to a strike among the workmen at Messrs. Hornsby's works is not for the moment available.* Mr. Strawson tells me that his new hand machine will throw spray many feet high. With its aid and the use of Paris green I entertain strong hopes that farmers, hop growers, and gardeners will be able to show good fight against their common enemies, and that at a very moderate outlay. Let me strongly urge all who are troubled by insect pests to think over what I have written, and act upon it.—D. LEE CAMPBELL, *Glaston Court*.

[Very strongly do we advise all our readers who grow fruit in localities where the greatest of all scourges to the trees abound—the winter moth and its voracious larvæ, the looper caterpillars—to "think over" very carefully what Mr. Lee Campbell has kindly written for the public benefit. He is generous enough to credit us with doing good service by publishing (in our issue above mentioned) magnified examples of the eggs and lurking places of the small but destructive foe of the orchard and fruit garden; but the chief credit belongs to our correspondent and his gardener for discovering the "nests" in which the eggs of the winter moth were ensconced, and placing samples at our disposal. So far as we know nothing of the kind that we were able to represent had been hitherto made public, even if the position of the nesting eggs were

* The strike, we believe, has terminated.

suspected; and now Mr. Campbell has added to the obligations of fruit growers by the careful and exhaustive experiments that we were aware were being conducted at Glewston Court, and of which he is able to say in respect to the use of Paris green that he "can report favourably all round." The remedy has been frequently mentioned in our columns as proving effectual in America, and the strength and method of applying the poison have been indicated; but we have not hitherto been able to publish any narration of the successful use of Paris green in this country, though it is said to have been found fatal to caterpillars and harmless to trees by a nurseryman. It will be perceived that caution is advised in the use of the arsenical preparation, and the strength of 2 ozs. to 25 gallons of water should not be exceeded; also the importance of keeping the water well stirred should be remembered, or the fine crystals will sink to the bottom of the vessel. Note should also be taken of the extreme minuteness of the early hatched caterpillars, which may, and doubtless do, abound on trees when their presence is not suspected. A magnifying glass reveals their existence when they are not visible to the naked eye. On the part of the fruit growers of the kingdom we thank Mr. Campbell for making known the result of his endeavours to conquer an enemy that, if unchecked, will assuredly render fruit growing impossible in some important fruit growing districts in the southern and midland counties.]

VARIATION IN PLANTS.

THE plant world affords abundant subjects of the deepest interest to students of all classes, especially to amateur and professional horticulturists, who are concerned, not only with the welfare of individual plants, but with their improvement either for ornament or use. An observer finds much to excite wonder in a most cursory review of the vegetable kingdom; the marvellous variety of forms, the wealth of floral beauty, the numberless valuable food and other products of so much importance to mankind, furnish ample material for investigation and thought. No section of this great subject having a direct bearing upon the art of gardening has, however, received the same scientific attention as the fertilisation and hybridisation of plants. Some of the most celebrated naturalists, as, for example, Dean Herbert and Charles Darwin, have studied it closely, experimented largely, and recorded their own with others' observations in books that rank amongst the standard works of the English language. Ever since the phenomena connected with hybridisation has been in some degree comprehended practical men have not been slow to take advantage of the means it afforded to increase the diversity, beauty, and usefulness of plants.

For ornamental purposes alone it was soon ascertained that the range of floral colouring in particular favourites could be greatly extended by a judicious and systematic crossing and seed-raising. Then, too, the same methods applied to edible vegetables and fruits, with farther aid of selection, have been found to yield important results by extending the seasons at which they could be obtained and by diversifying their flavours. Such beneficial results as these, in addition to the interest attaching to the matter, are sufficient to prove that the subject is worthy of close attention on the part of all engaged in horticulture, especially as there is still abundant scope for experimental research. In the following remarks it will not be possible to completely review the whole of this extensive subject, but we can discuss it generally; and in pointing out the more important facts we may stimulate others to closer observation, and upon the development of this faculty depends a good deal of what is termed successful gardening.

The power of man in the production of plant forms depends entirely upon the inherent tendency to variation marking the greater portion of the vegetable world. In our meadows, heaths, and in any uncultivated district it is easy to find examples of this amongst the native plants of this country. The differences are often very slight, and such as only an experienced eye could detect; but, on the other hand, forms are occasionally found undoubtedly having a common origin, yet with strongly marked characters that cannot be overlooked. It is only necessary to refer to the British Ferns for instances illustrating these observations, but many flowering plants afford examples of scarcely less value. Of course variations in one species are here referred to, but what we regard as a species is simply a group of individuals agreeing in certain characters and possessing some peculiarities of formation by which they can be distinguished from all other members of the vegetable kingdom. Now, we find amongst animals of one species,

or even of one variety, sufficient characters to render them easily distinguishable from their near relatives, and by close observation it is possible to detect, and even become familiar with, points of difference that in the same way mark the individual plants raised from one species or one parent. Here we have the commencement of a divergence that may be perpetuated and increased, with the result that a variety with more or less strongly marked characters may be ultimately secured, or forms of even greater value may be obtained, for in many races of cultivated plants variations have been raised by accident or design that if found in a state of Nature would probably have been regarded as distinct species.

Botanists have frequently had to modify their views respecting what constitutes species in some families of plants, as the discovery of other forms intermediate between those already known have linked apparently distinct species together so closely that their amalgamation became necessary. What may be termed the capacity for variation in particular species cannot be discovered at a glance, and it is only wide knowledge of related forms, or experience of the plant's behaviour under cultivation that permits an approach to an accurate opinion to be formed. All do not possess the same elasticity, for some species preserve their chief characteristics unchanged in a wild state, few or no variations are found, and they present constant types, often under very diverse circumstances, soil, situation and climate. Some of the most widely distributed plants are examples of this, and travellers are almost startled sometimes by the appearance of a familiar plant, true in all its characters, but thousands of miles from its British home.

Others, again, are influenced to a certain extent by their surroundings, and we thus have what are termed geographical varieties, all, however, tolerably true to the main type. There are still others that vary greatly in one locality, where the differences in situation can count for little, and the variation depends upon the characters being less firmly fixed, and consequently more readily influenced by cross-fertilisation.

Under cultivation we find these various classes of plants behave very differently. Some absolutely refuse to submit to man's interference or efforts to alter their characters, and retain their distinctions unchanged. Others after a long course of culture seem to have their constitution so disturbed that variation is induced, and when once this is effected it becomes a matter of perseverance, in some degree, as to how far it shall be extended. Those which have been noted as variable in a wild state usually become still more so under artificial conditions. They give rise to an astonishing diversity of forms, and their fixity of character being once broken down they are like plastic moulds in the hands of the experienced cultivator, who within a certain range can obtain almost any combination of tints or floral form he desires.

In a state of nature we find, therefore, as far as necessarily limited observations can determine, that the variability of species differs greatly, but under cultivation we also see the tendency to variability considerably increased. Altered conditions of existence are the main causes of this, and it follows if a wild plant by any chance should find a home and thrive in a soil and situation greatly different from that which its relatives usually occupy, divergence of character might be induced and inherited by its descendants. Here we have the first step to a variety, and the differences may become accentuated in succeeding generations, particularly if the character so developed affords the plant any help in preserving its existence by ensuring fertilisation, or by a more vigorous constitution enabling it to resist climatic evils. Such variations might and do occur without cross fertilisation, simply from the influence exerted upon the plant by different conditions of location. When a change is once started it is soon extended, and it is then that cross-fertilisation comes into action with more marked force.

Amongst many cultivated plants variations are commonly obtained from the self-fertilised flowers of one plant without any attempt at crossing, but it is true that the results may often represent reversion to the characters of former parents, or a combination of these, rather than absolutely fresh productions. Examples are afforded by many of the garden annuals and other plants usually raised from seed, for it is most difficult to keep any selection of these true without large quantities are grown together, and even then much "weeding" is often required. Under cultivation therefore, as in Nature, variability is to some extent caused by altered conditions of existence, and subsequently many variations that appear, may be simply reversions or combinations of pre-existing characters.

In gardens another form of variation plays an important part—namely, "sporting;" but it rarely happens that Nature makes any provision for the preservation of such freaks, and it is only through propagation by cuttings, grafts, and buds that so many have been multiplied artificially. It is seldom that they are reproduced from seed, though an alteration has been effected that may have

important ultimate results. "Sporting" commonly occurs in the foliage and growth of plants. The leaves become variegated, or are cut and altered in shape, examples of which are seen in Hollies, Lilies, Maples, with many others of our trees and shrubs. Such productions can only be perpetuated by vegetative increase, and if they take place in wild plants they die out with that upon which they originated. An exception may perhaps be found in the case of the whole or a large portion of an herbaceous plant with creeping roots having its foliage variegated, and some of the variegated Grasses thus have the power of increase without artificial assistance. "Sporting," as everyone knows, also takes place in flowers, the Rose and the Chrysanthemum furnishing abundant examples of new forms originating in this manner. There again, however, the variations cannot be perpetuated by seed, and resort must be had to cuttings in the Chrysanthemums or budding in the Roses, and it is not likely flower sports would be more readily preserved in a wild state, so that, as with leaf sports, it is extremely probable the majority perish.

So far we have only been dealing with variations as apart from natural hybridisation or cross-fertilisation, but we must now turn our attention to this large and important portion of the subject, and it will be seen that several of the points already detailed have a considerable bearing on the matter.—L. CASTLE.

(To be continued.)

PHAIUS GRANDIFOLIUS.

DIRECTLY signs of growth are visible repotting should be done. The old soil should be carefully removed from amongst the roots, and the plants returned to clean pots of the same size. These plants do well in a compost of fibry loam two parts, one part fibry peat, and the other part of leaf mould. To this may be added one-seventh of decayed manure that has been passed through a fine sieve, a liberal quantity of coarse sand, a little charcoal, and a few quarter-inch bones. The pots should be moderately drained, and the base of the pseudo-bulbs just raised above the surface of the soil. After potting place the plants where they can be kept close and in a moist atmosphere. If practicable plunge the pots to prevent watering as long as possible. The soil should never be allowed to become dust dry, but water must be given carefully until growths extend and roots are forming freely. If they are over-watered in their early stages the young growths are liable to become spotted. This must be carefully avoided, or the foliage is disfigured the whole of the season. If the plants are infested with scale clean them thoroughly, or with increased heat they will soon attack the young growths, which for some time cannot be cleaned without injury.

SOBRALIA MACRANTHA.

As signs of growth are visible at the base potting may be done. If the compost is in good condition and the plants need larger pots this can be done without disturbing their roots. Use for a compost good fibry peat, charcoal in lumps, and sand; a layer of sphagnum moss may be placed on the surface. The pots should be one-third filled with drainage, and the plants slightly elevated above the rim. Plants that have become crowded with growths may be carefully divided. If the compost at the roots is in good condition they quickly recover and grow freely. Being a strong free grower this plant bears division well, and will make strong flowering growths the first season. They need judicious watering for a time afterwards.

THUNIA MARSHALLIANA.

Plants that have had a lengthened period of rest may be started into growth. Being a strong free grower the compost advised for Phaius may be used. This plant is often grown too close and too warm, with the result that its growths run up several feet in length, and are too soft to flower. Directly they start into growth they should be potted, and then grown in a light position in a vinery or in an intermediate structure fully exposed to the sun, and where air can be admitted daily to maintain a firm sturdy growth. Plants given this treatment will make stout growths, and flower when they are 18 inches to 2 feet high. These plants may be grown one or two good pseudo-bulbs in each 5-inch pot, or a number together in those of a larger size. For effective purpose while in the flower the

former is probably the best. Once these plants are rooting and growing freely weak stimulants will prove beneficial.

DENDROBIUM PULCHELLUM.

This is a charming little Orchid for suspending from the roof in baskets. It grows luxuriantly in any moist shady position, but requires to be thoroughly ripened to flower it well. It grows and roots so freely that there is no difficulty in establishing it in pans or baskets. The baskets should be nearly full of charcoal, and the remaining compost may consist of peat fibre and sphagnum moss, or both mixed together. Rooted portions soon establish themselves, and all the care that established plants need is to remove as much of the old moss as possible, supply fresh, and then peg the pseudo-bulbs on to it. Do not over-water these plants in their early stages of growth; but when once they are growing freely the syringe may be used twice a-day, and the baskets soaked occasionally.—ORCHID GROWER.

L'ORCHIDÉENNE.

THE eighteenth meeting of this Society took place in Brussels on the 13th and 14th April. To meet a popular demand these Exhibitions have been extended to two days, which speaks well for the increasing love and interest in Orchids and their culture in this country. The Show was held as usual in the conservatory of the establishment L'Horticulture Internationale (Linden), Park Leopold. The exhibits, although not so numerous from a point of numbers, they were exceeding those of the last meeting in quality. Several interesting and fine Orchids were staged. The Jury, over which M. Kegeljan presided, was composed as follows:—MM. Lubbers, Secretary; Massange de Louvrex, Rodigas, Miteau, Wallaert, and De Meulenaere. M. G. Warocqué, the President of the Society, was one of the chief contributors, and especially noticeable were a marvellous variety of *Cattleya Mossiæ* Madame A. Warocqué, with blooms of immense size; *Odontoglossum crispum fastuosum*, *crispum guttatum*, several fine varieties of *O. luteo-purpureum*, *O. Reichenheimi*, carrying an enormous spike, and a grand variety of *O. Ruckeri*. Prince Metschersky presented a beautiful variety of *Cattleya speciosissima* named Regina Olga, the large rose sepals and petals of which are beautifully mottled with purple. M. Jules Hye-Leysen contributed among others a splendid variety of *Cattleya Mendeli*, several fine forms of *O. triumphans*, one of which being of very rich colouring and large size. The Comte de Bonsies staged a fine variety of *Cypripedium Mastersianum* and *Harrissianum nigrum*. M. Van Turschoot also contributed a small group, among which were a fine variety of *Miltonia Warszewiczii*, well flowered. Dr. Van Canwelaert sent a finely spotted form of *Odontoglossum crispum*, *O. tripudians*, and others. Madame Gibeze, Tens, France, contributed as usual to the success of the meeting by sending a number of cut blooms. A well flowered specimen carrying an enormous spike of *Oncidium sarcodes* was shown by Dr. Capart. M. Van Lausberge sent a well flowered plant of *Pholidota gracilis*, not a showy Orchid but very interesting. M. Pourbaix, Mons, also contributed a small group, among which were a well flowered piece of *Cælogyne ocellata maxima*, a species often despised, but when seen to perfection is most lovely. A magnificent variety of *O. vexillarium splendidum* was staged in a large group by L'Horticulture Internationale (Linden). The plant carried four spikes, with flowers of very large size. The splendour of colour must be seen in nature to realise the beauty; description is impossible. Noticeable were also several fine varieties of *Vanda suavis* and *tricolor*, well flowered specimens of *Lycaste gigantea*, a large number of choice *O. crispum*, *Phalænopsis Stuartiana*, *stellata*, and others. In the group of M. Peeters we noticed *O. hystrix giganteum*, *O. nebulosum*, *O. Pescatorei*, *O. Oerstedti majus*, *O. Jenningsianum*, *O. luteo-purpureum*, beautiful spotted form of *O. crispum*, and a large specimen of *O. cuspidatum*, well flowered; *Lycaste Skinneri alba* and *gigantea*; *Cymbidium cburneum*, and the rare *Epidendrum Wallisi* carrying several fine spikes of bloom, and a fine specimen of *Cypripedium hirsutissimum*. A number of certificates were awarded.

NOTES ON FRUIT TREES—APPLES.

(Continued from page 325.)

SITUATION.

UNQUESTIONABLY the best site for a fruit garden or orchard is a slope inclining to points between south-east and south-west. A gentle slope due south, or preferably facing a little south-east, so as to face the sun at about eleven o'clock in the forenoon, is the most suitable. Ground inclining due east is objectionable from its exposure to the cold winds that often prevail from that quarter during the spring and early summer months, the advantage of

shelter from the strong gales that prevail from the west very often in late summer and autumn being counterbalanced by the incidental deprivation to the site of the afternoon and evening sun. A due west incline is even more objectionable, by reason of the winds that prevail from that point during the late summer and early autumn months, a "windfall" of Apples being a serious disaster. A south-west aspect is also inadvisable, on account of the strong gales occurring about the time of the autumn equinox, otherwise it is the most desirable, as westerly breezes are always warmer and moister than easterly. Tolerable results may attend planting on slopes inclining northwards. Trees so located may have the blossoming period retarded so as to escape frosts, which destroy the crops of those on southern exposures, but the crop thereby insured will not compensate for the greater perfection those on the southern incline generally attain, as fruit on cold exposures does not acquire the size, colour, or quality of that grown in locations having the full benefit of the sun, particularly the late summer and autumn rays.

Slopes should not be other than commanding a majority of the solar rays and not too steep, as we have to consider the supply of moisture—the rainfall and its appropriation as well as catching sunbeams. For orchards the incline ought not to exceed a fall of 1 foot in 10 feet, but with dwarf culture and ridge or terrace planting the incline may be considerably more, as the steeper the slope up to 65°—the perpendicular in that case being about half the base—the greater benefit will be derived from the sun's rays, and being elevated the trees would not be as liable to suffer from spring frosts as those on low ground, as increased surface for absorbing correspondingly enlarges the radiating, which will counteract condensation. Granted slopes facing south-east to south-west, properly sheltered from west to north round to east, it is certain as large, highly coloured, rich, and better—because juicier—Apples could be grown as any imported. Elevation, however, makes a difference of about $\frac{1}{2}$ ° in every 100 feet of altitude, but the inclination of the ground to the sun more than compensates for any loss of heat through altitude, and the rarefaction of the atmosphere is singularly solidifying of the growth and concentration of colour and quality in the fruit.

The lower part of a gentle declivity in sheltered localities is perhaps to be preferred for an orchard, yet where the ground is not liable to suffer from drought, a slope of not less than 1 foot in 30, at an elevation fully one-third of the hollow or total depth, is decidedly preferable to a site at the foot of a slope, as there is not only danger to be apprehended from spring frosts, but the water draining from the higher ground making it wetter (I readily admit richer, and securing greater uniformity of moisture), conduces to a late growth, with its attendant immaturity of wood and resulting canker. A very low situation may have an alluring depth and richness of soil, and efficient draining present no obstacle, yet it is not a good site for an orchard, as it occasions the condensation of moisture—with fog and frost. Level ground has the advantage of being easily worked as compared with inclining, and is not so liable to suffer from drought, as the rain does not run off as after a dry period on slopes, but penetrates and keeps the subsoil moist at all seasons, superfluity being carried off by efficient drainage. A rainfall of 24 to 26 inches will meet all requirements of the Apple as to moisture on the lower part of slopes as well as on level ground, as also slopes that have not a sharper incline than 1 foot in 30. It is necessary, however, to take into consideration the nature of the subsoil, for where there is a stratum of gravel or other natural drainage under the loam the rainfall, though it be 24 to 26 inches, may be inadequate, and in the case of slopes sharply inclining something more, through the drying influence of the under strata, it may be necessary to afford the requisite moisture in dry periods during the growing season. A command of water from a higher source should always be kept in view when treating with slopes. In planting slopes much may be effected by furrows between the rows of trees in preventing the water running off in summer without staying so long as to be absorbed by the soil, and in localities where the rainfall is excessive, slopes and the ridge system of planting may be a necessity alike of getting it into the soil when wanted, and causing its equal diffusement throughout the slope, for it necessarily follows when there is no such provision for catching and keeping the rain, that it will pass off according to the inclination, and whilst the base is saturated the upper part is "dry as dust."—G. ABBEY.

(To be continued.)

THE DAFFODIL CONFERENCE.

THE real business of the Daffodil Conference, in the Royal Horticultural Society's garden at Chiswick, commenced on Wednesday, April 16th, when Professor Michael Foster took the chair at 2 p.m. in the conservatory or vinery, and opened the proceedings with an address.

He was supported by the Rev. W. Wilks, the Rev. G. H. Engleheart, Mr. F. W. Burbidge, Mr. James Walker, and Mr. C. R. Scrase-Dickens, Secretary of the Narcissus Committee. There was a good attendance of Fellows and visitors, and much interest was manifested in the proceedings.

Professor Foster said he had some connection with the first Daffodil Conference in 1884, which took place at South Kensington, and he thought that regarding the Exhibition provided this year, and the place where it was being held, they had good reason to congratulate themselves, for if they were not sitting under their own Fig tree, they were at least under their own Vines. "We are," said Professor Foster, "essentially gardeners brought together by our love of flowers, and the object of the meeting is to increase our love of the Daffodil in particular. It has been rightly said that we can safely let alone the good and the true, but what we have to do is to take care of the beautiful. So it is our desire to take care of the Daffodil." He then referred to the importance of correct and systematic nomenclature, and remarked that the leading points in a good name are that it should be one which can be written, read, spoken, and remembered with ease. Where possible the name should indicate the nature of the plant or its chief characteristics, but the difficulties in the way of the general adoption of such a scheme are often insuperable. The Narcissus Committee had, however, performed useful work and simplified the names to a great extent, as well as pointing out the synonyms and assisting in the removal of much confusion. Much valuable information had also been gained respecting the Daffodils, some of which they would be entertained with in the lectures to follow.

The Chairman then announced the awards of the Judges as follows: The silver cup offered by the Rev. W. Wilks was presented to the donor. Two silver medals offered by Messrs. Barr & Son were awarded to Mr. C. W. Cowan, Valleyfield, Pennycuik. A gold Banksian medal was awarded to Messrs. Barr & Son, King Street, Covent Garden, for their large collection of Daffodils; a silver-gilt Flora medal to Mr. James Walker, Ham Common; a silver Flora medal to Messrs. J. Veitch and Sons, Chelsea; and a silver Banksian medal to Mr. W. Poupart of Twickenham.

The Secretary, Mr. C. R. Scrase Dickens, then presented a report of the work performed by the Committee since its formation in 1886. The desirability of adopting some uniform system had led to the institution of a committee of specialists, which held meetings in March, April, and May of 1886, and each succeeding year. The first and chief part of the business was the substitution of English names for Latin titles in the case of all seedlings raised under cultivation. They had also adopted a method of registering the names of those varieties considered most distinct. In this way fifty-four had been recognised, the names of which follow:—*Pseudo-Narcissus*—Automedon, Ard Righ, Challenger, Captain Nelson, Troilus, Achilles, Vicar of Lulworth, Golden Prince. *Major*—Henry Irving, Emperor, P. R. Barr, Distinction, The Czar, Glory of Leyden, Madame de Graaff, Samson, Santa Maria. *Bicolor*—Empress, John Horsfield (Horsfieldi), Camoens, Dean Herbert, J. B. M. Camm. *Moschatus*—Leda, Minnie Warren, Gladys, Niobe, Little Nell. *Incomparabilis*—Sir Watkin, Autocrat, Queen Bess, Gloria Mundi, Mary Anderson, Lulworth, C. J. Backhouse, Princess Mary. *Backhousei*—William Wilks, Nelson's Orange. *Bernardi*—H. P. Buxton. *Tridymus*—A. Rawson. *Leedsii*—Duchess of Westminster, Acis, Beatrice, Gem, Minnie Hume, Madge Matthews. *Barri*—Conspicuous. *Intermedius*—Sunset. Also Madame Plenp, Lena, Mrs. Walter Ware, Duchess of Teck, Golden Vase, Miss White. The Committee does not attempt to deal with sub-species, or those to which the botanist would apply Latin names. Mr. Dickens mentioned that in 1887 attention was called to a disease that caused much loss amongst the Narcissi, but since then there had been no opportunities of investigating the matter.

The next business was the reading of the following admirable paper by Mr. Burbidge.

HISTORY OF CULTIVATED NARCISSUS.

[Abstract of a paper read at the Narcissus Conference held at the Chiswick Garden of the Royal Horticultural Society on April 16th, 1890, by F. W. Burbidge, M.A., F.L.S., Curator of Trinity College Botanical Gardens, Dublin.]

MR. BURBIDGE prefaced his lecture by quoting the sing-song lines of the children—

"Queen Daffadowndilly has come into town
In yellow petticoats and a green gown,"

and remarked how singularly appropriate it seemed to him, this holding of a four-days tournament, under the auspices of Queen Daffodil, in the time-honoured and memory-haunted precincts of the Chiswick Garden, a garden visited years ago by Hawarth and Herbert, Salisbury and Sabine, Lindley, Sweet, Ellacombe, and many others of the former lovers of the Narcissus as a beautiful spring flower. The lecturer then pointed out that a love for these fragrant blossoms was almost as old as human history itself, and gave quotations from the Homeric "Hymn to Demeter" (B.C. 1000), and from the "Œdipus at Colonus" of Sophocles, both of whom mentioned Narcissus Tazetta for its glittering beauty and fragrance nearly 3000 years ago. It was next observed that the written history of this delectable flower showed the duality of human progress, since all the most noble objects of human interest had first of all obtained honourable notice (as in the present instance of the flower Narcissus) from the great poets, who were really seers or prophets, instinctively gifted or inspired; hence the bards had ever been, and were still, the true and reliable guide posts or milestones along the great highway of human life. Again Mr. Burbidge emphasised the fact that

the best of practical workers were successful, and their best work permanent in proportion to their natural instincts, rather than to artificial training, although of course it was conceded that apt instincts and careful training as co-existent were better than either alone. The main fact remaining that while the poets lead all the progress, the practical men and the scientists follow, and illustrate the truth and force of the poet's teaching.

The lecturer here observed that much of floral history must ever remain unknown. We may nowadays, for example, never know what was the favourite flower of Helen of Troy, or that of the great Cleopatra, Egypt's fascinating Queen, but he remarked that both these great and beautiful women must often have seen the clustered Narcissus (*N. tazetta*), and even if blue-eyed Helen did not, like Persephone, stoop to gather it from the grass of the Grecian meadows, it was more than probable that incense-loving Cleopatra when tired of fiery Pomegranate buds, had often worn clusters of the Narcissus in her blue black hair, just as do the wives and daughters of sunshiny Egypt and of Arabia to-day.

Turning from poetry and speculative "guesses at truth" the lecturer next emphasised the fact that Mr. W. Flinders Petrie, the celebrated Egyptologist, had recently discovered—that is to say, in 1888—at Haward in Egypt actual flowers of *Narcissus tazetta* as before alluded to; these blossoms having been deftly woven into funeral wreaths or votive garlands as long ago as the first century before the Christian era. These offerings to the honoured dead are supposed to have been made by Greek residents in Egypt, and are now preserved in the collections at Kew, where they may be seen. After the poets of Greece, however, in chronological order, come the early Greek physicians, such as Hippocrates, and at a much later date Galen, both of whom recommended the usage of the poisonous or narcotic roots of *Narcissus* for anæsthetic and medical purposes. Theophrastus of Eresus (B.C. 374-286) described the plant, and he appears to have been the first to allude to its increase by means of seeds, which he tells us "were sometimes gathered for sowing," and he further says that the fleshy roots or bulbs were sometimes planted. As a beautiful and variable wild and garden flower in southern and western Europe, in N. Africa and in the East, there is no doubt but that this flower has ever been popular; but so far as English gardens are concerned the *Narcissus* seems to have first become famous during or shortly previous to Elizabethan times, when all the greatest poets mention it, and during the same epoch both Gerard and Parkinson, the Royal herbalists of their day, illustrate or describe at least a hundred kinds, and of these old Gerard (1597-1633) especially writes that "all and every one of them" abounded in London gardens. No doubt the common yellow Daffodil of the woods and meadows in "merry England" had been popular as a flower for the making of festive wreaths or garlands long before exotic kinds were introduced and cultivated in gardens, since these are mentioned by Chaucer and other early English poets just as they were by those of ancient Greece. When the great wave of early seventeenth century culture spread over Europe choice *Narcissi* were imported from Constantinople and the Levant generally, as Gerard quaintly tells us was the fact, "along with other bulbous flowers," these latter including the then more attractive Tulip, and no doubt the Hyacinth as well.

Mr. Burbidge next alluded to the old Dutch paintings of garden flowers, dating from 1590 to 1650, and in which many kinds of *Narcissi* find portraiture. He in particular instanced one picture, now to be seen in the Louvre (No. 477)—viz., "Triomphe d'Amour," the figures by Zampieri, the wreath of flowers surrounding them being by Segher's "Le Jesuit d'Anvers," this wreath containing life size portraits of fourteen or fifteen kinds of *Narcissi* and of Daffodils, some of which are the rarities of to-day. Other pictures exist in the "Musée des arts decoratifs," in our own National Gallery, and other collections, public and private, in which these flowers find a place; and even our English Cleopatra (Queen Elizabeth) seems to have been fond of them, since in a portrait of her by Zuccherò—hanging in the Examination Hall of Trinity College, Dublin—there is a flower of the purple ringed or Poet's *Narcissus* painted in a prominent position by her side. Again, in the rare old folios and other books of the same epoch (1590-1650) many species and varieties, including several natural or wild hybrids, are illustrated either by wood engravings (mostly made at the then celebrated Plantin or Plantin-Moretus press at Antwerp), or by copper plate etchings or engravings. Especial mention was made of the works of the pre-Linnæan botanists, such as L'Obel, Dodoens, L'Ecluse (who was one of the first and best of European plant collectors), Jean Robin, Gerard, and Parkinson. Mr. Burbidge also alluded to some rare works, such as De Bry's and Sweet's "Florilegia;" the "Hortus Floridus" of Crispian Passe, jun.; "Jardin du Roy," and "Theatrum Floræ," and to the ill-fated book of drawings issued by the Rudbecks in 1702, of which only two or three copies exist, most of the issue—wood-blocks, &c.—having been burned in the great fire at Upsala in 1702. It was stated that the only complete copy of this last work is that in the Sherardian Library at the Botanical Gardens, Oxford; but there is also a copy, less perfect, in the Banksian Library, British Museum, which contains all the woodcuts illustrating the *Narcissi*. It was also stated that portraits of two of the beautiful White Spanish Daffodils were seen by Salisbury (a noted authority on these flowers about a century ago) in the palace at Fontainebleau. They were worked in coloured silks on a fire screen, said to have been given by Henry IV. to La Belle Gabrielle. Salisbury especially tells us in the "Transactions of the Royal Hort. Society," vol. i., that these representations were most natural and life like, the legend worked beneath them being "Coque-

lourdes Blancs, 1598," or the year before John Gerard, the barber surgeon, published his famous "Herbal," which, bulky as it was, gave a great impetus to the general study of botany and gardening in England for years and years after it first appeared.

Mr. Burbidge then dealt with the history of the cultivated and wild *Narcissi*, and to the now numerous and ever increasing garden hybrids and seedlings, as also to the men like Herbert, Leeds, Backhouse, and Nelson, &c., who have in the main enriched our modern gardens with the most beautiful forms and phases of this flower. A considerable and valuable portion of Mr. Burbidge's paper consisted of a chronological history of the genus from the days of Homer to those of Oscar Wilde! In this tabulated list mention is made under dates of all the principal poets, physicians, philosophers and botanists who have alluded to the odour, beauty, uses, &c., of this now fashionable flower, or with whose names it has become connected. Mr. Burbidge did not read this portion of his masterly paper, as being too long and too full of dates and detail, but as it will probably be published in the Journal of the Royal Horticultural, which will be issued as soon as possible after the Conference is over, it may then be perused by all interested in the subject on which it treats. It forms a concise and popular index to the principal men and books, and will be found handy for reference purposes.

The Rev. G. H. Engleheart, M.A., who has given much attention to

FIG. 49.—NARCISSUS MADAME DE GRAAF (see next page).

the *Narcissus poeticus* group, then gave some interesting particulars respecting the chief varieties and their relationship to the other groups, and after a short discussion the meeting terminated for the day.

On Thursday, April 17th, Mr. J. G. Baker, F.R.S., took the chair shortly after two, and opened the proceedings with a short address, referring to the botanical classification of the genus, and to the fact that with regard to the Daffodils generally they are now out of the hands of the botanists and in those of the hybridists. He mentioned that when he first began to give his attention to Daffodils they were only seen as wildings or in small numbers in gardens, and it was very satisfactory to see the progress made and the popularity they had now attained.

The Rev. Wolley Dod proceeded to review the characters, distribution, and classification of the varieties of *Narcissus pseudo-Narcissus*. Much interesting matter respecting the geography of Daffodils was given, especially with regard to their introduction to Ireland. He stated that many had been puzzled to account for the number of distinct good varieties found wild in Ireland, but he thought it was probably due to the fact that at one time Daffodils were supposed to possess some medicinal properties, and the old Italian or Spanish monks would be likely to take bulbs or obtain them from their friends for planting around their residences. With regard to the classification of the varieties he adopted the following sections:—1, Discolor, in which the perianth and corona were differently coloured. 2, Concolor, in which the distinction of colouring was not observable—that is, the perianth and corona were uniformly of some yellow tint. 3, Pallidus; 4, Albus; and 5, Muticus. Mr. Wolley Dod then mentioned the chief varieties under each section, describing their characteristics.

DAFFODILS FOR MARKET.

Cultivators present on Thursday evidently appreciated Mr. James Walker's brief, pithy, practical paper; it was listened to with the

greatest attention and greeted with much applause. Mr. Walker said that if at the last Conference in 1884 they were justified in estimating the number of Daffodils cultivated in this country at 10 millions they might safely assume that now there are 200 millions of bulbs. The question is, Will they continue to pay, as they are increasing so rapidly? There had been a fall of quite 50 per cent., and last year some were sold as low as 9d. per dozen bunches of a dozen flowers each, though it must also be said that the price had been as high as 12s. for the same number. Large quantities are now imported from the Scilly Islands, the South of France, and the Channel Islands, and there are supplies in the market from the end of January until the middle of May.

Reverting to the best varieties for market culture he said that it would be more convenient to take them in the order of the schedule list. Class 1 (Corbularia), class 7 (Triandrus), and class 9 (Gracilis, &c.) would be excluded. Commencing, therefore, with class 2, Yellow Trumpet Narcissi, he considered Emperor in size, substance, and colour one of the best; Maximus is a fine deep yellow; Golden Spur, Countess of Annesley, Tenby, Spurius, and Edward Leeds, all being approved for supplying flowers in large quantities. In class 3 (the bicolors) all the varieties are good, but he preferred Empress because it increases faster, every offset flowers, and the flowers last longer. Horsefieldi is also a valuable variety, but he gave it the second place, though in a discussion which followed some preferred that variety. Class 4 was devoted to the sulphur and white varieties of the Ajax type, and Mr. Walker stated that these are always a drag in the market, the flowers are soft and do not stand well. He named Mrs. F. W. Burbidge and cernuus pulcher as two of the best. Class 5, the incomparabilis family, is a large one, and much sifting is required to secure the best market varieties. Sir Watkin is of robust constitution, a bold flower and most useful. A capital companion is Lady Watkin; Gloria Mundi and Princess Mary are also good; Barri Conspicuous, Maurice Vilmorin, and W. Ingram; Duchess of Westminster, Madge Mathews, Gem, and Minnie Hume being selected from the Barri and Leeds type. In class 6 the only forms of market value are those included under Nelsoni. In class 8 of the poeticus group ornatus is the foremost in all respects, with poetarum and recurvus for succession. The Burbidgei varieties are not popular, but Constance, John Bain, and Mary might be grown in a limited collection. The Campenelle N. odoratus and the variety rugulosus are both useful. Amongst the doubles he specially mentioned the double N. poeticus, which he said he had never succeeded in forcing, and it was at times apt to go blind. Summarising the points with regard to the selection of varieties, Mr. Walker said it was important to secure large flowers, decided colours, and those that will last well.

In describing his method of culture which has been previously given in this journal he remarked that some varieties require much heavier soil than others. In 1881 he planted a bed of Daffodils in strong loam; after two years Capax and cernuus plenus had disappeared, while Emperor and Empress had increased fourfold. He also observed that what may be termed garden varieties generally needed a liberal supply of manure in the soil; for others it was not employed. The land is ploughed, harrowed, and rolled in preparation for planting, which is regulated by a drill. The bulbs are lifted, dried, and cleaned, and he starts planting in August with N. poeticus ornatus, all planting being finished in September. The flowers are gathered before they expand, and placed in vessels of water under glass or in sheds, and some judgment is required to gather the flowers at the right stage. With annual lifting and planting, close attention to business, and hard work, there was no need to fear competition.

The Chairman complimented Mr. Walker upon his admirable paper, and in response to his invitation to join in the discussion, Messrs. Jenkins and Fraser offered some remarks, to which the lecturer replied, and the meeting concluded with votes of thanks to the Chairman, readers of papers, and the exhibitors, proposed by the Rev. W. Wilks, who, in referring to some remarks respecting the difference in the quality of the flowers shown by nurserymen and amateurs, said that the quantity relatively grown made the difference, for while the amateurs had ten plants, perhaps the nurserymen had 10,000, and he asked if it was not much easier to cut a dozen flowers from the latter number than the former? He believed that with equal facilities amateurs would always hold their own. The vote was carried unanimously, and the Conference terminated, but the Exhibition was not closed until the following afternoon.

Amongst the varieties that merit special notice we have selected two for illustration this week, which are very distinct in character. Fig. 49, page 337, represents one of the Ajax section named Madame de Graaf, which is included amongst these "registered" by the Narcissus Committee. It belongs to the white or sulphur coloured section, and has a large flower of most elegant shape, either white or with a sulphur tint in the corona that is equally pleasing.

The other, fig. 51, page 345, is named Queen Sophia, and belongs to the incomparabilis group. It has pale yellow or sulphur perianth segments, and a much deeper coloured spreading and frilled corona, the tint being a bright shaded orange, verging in red. Both varieties are of good constitution and distinct in their respective classes.

FRUIT PROSPECTS.

I HEREWITH send you prospects of wall fruit here as indicated by the amount of flower on the various trees. This garden is divided into two divisions, and the No. 1 division is about 20 feet higher than No. 2,

which may account for the somewhat variable character of the flowering of the trees, and in No. 2 the trees are all younger and soil slightly stiffer. We have a 16 feet border around the wall, and at the base of the wall I annually put a good dressing of ashes, which not only makes it more pleasant to walk upon, but materially assists the fertility of the trees. Orchard trees are looking well. I will send notes on them next week.

South Wall, 1st Division.—Apricot Moor Park, under average; May Duke Cherry, one mass of flower; Early Orleans Plum, ditto; Doyenné du Comice Pear, good show, average; Comte de Lamy Pear, average show; Kirke's Plum, average; Ne Plus Meuris Pear, average; Winter Nelis Pear, average; Transparent Gage Plum, one mass of flower; Moor Park Apricot, under average; Glou Morceau Pear, none; Jargonelle Pear, very fine show; Autumn Bergamotte Pear, good; Reine Claude de Bavay Plum, average; May Duke Cherry, full of flower; Bigarreau Cherry, ditto; Apricot Kaisha (set), average; Marie Louise Pear, average.

West Wall, 1st Division.—Principally Plums Victoria and Magnum Bonum, of which there is only a very moderate show of flowers.

East Wall, 1st Division.—Doyenné d'Été Pear, good show; Pitmaston Duchess Pear, good; Beurré Diel Pear, average; Easter Beurré Pear, average; Williams' Bon Chrétien Pear, very full. Plums and Currants and Gooseberries on this wall have an average show of blossom.

South Wall, No. 2 Division.—Fig Brown Turkey promises well; Apricot Kaisha, bad; Peach Stirling Castle, under average; Apricot Moor Park, average; Royal George Peach, average set; Apricot, average set; Waterloo Peach, average; Dymond Peach, under average; Marie Louise Pear, good show; Knight's Monarch Pear, scarcely any; Crassane Pear, fair show; Glou Morceau Pear, one mass of flower; Nec Plus Meuris Pear, average.

East Wall, 2nd Division.—Plums: Victoria, under average; Golden Drop, under average; Jefferson, under average; Kirke's, none; Jefferson, one mass of bloom, and are two weeks earlier than last year. Pears: Citron des Carmes, one mass; Louise Bonne, ditto; Autumn Bergamotte, average; Winter Nelis, very little; Louise Bonne, average; Doyenné du Comice, few but fine; Marie Louise, good; Citron des Carmes, one mass; Josephine de Malines, under average; Jargonelle, good show. Morello Cherries on north wall promise well.

West Wall, 2nd Division.—Pears Williams' Bon Chrétien, average show; Comte de Lamy, average; Louise Bonne of Jersey, a picture (this tree measures 30 feet by 10, and from which last year I gathered 2 bushels of fine fruit); Forelle, average show; Thompson's, average; Winter Nelis, good; Duchesse d'Angoulême, one mass of flower; Catillac, ditto; Nec Plus Meuris, average; Marie Louise, average; Doyenné du Comice, average; Golden Drop Plum, above average show; Kirke's Plum; Glou Morceau Pear, average; Beurré Giffard Pear, owing to having been removed the blooms were picked off; Williams' Bon Chrétien Pear, average; Winter Nelis Pear, scarce any.

North Wall, 2nd Division.—Catillac Pear, good show. The trees on this wall are principally late Plums, which are showing very scantily, but each tree has a few dozen flowers. In this district I find the Victorias do not bear heavy crops annually. Bush Plums have lost their blossom owing to the severe frost experienced on March 24th.—W. A. COOK, *Compton Bassett Gardens, Calne, Wilts.*

SPRING FLOWERS AT HOME AND ABROAD.

NO. 2.—HYACINTHS AND TULIPS.

(Continued from page 318.)

WITH the whole stock of the largest growers in Holland under requisition for furnishing material with which to compose the fine prize groups an opportunity such as rarely occurs is provided for a comparison and selection of the best varieties. The following were noted as amongst the finest of those shown at Haarlem, and it will be seen that many of them are old favourites with us, while others are less familiar. La Grandesse was shown in splendid condition, and this beautiful Hyacinth may be classed as one of the best of the pure whites. The bells are very large, and in good examples so closely furnish the spike as to form a broad compact truss. It is not a dear variety, and everybody should grow it. Anna is another charming variety of very much the same character, though not so well known. Madame Van der Hoop has larger bells of great substance, but the truss is not quite so good as in the two other whites named. Dr. Windthorst is a new white of considerable beauty, with a remarkably well-furnished and symmetrical truss, and is well worth looking after for exhibition purposes. Amongst the shaded white or blush-coloured varieties Princess Amalia holds a very high place. The bells are large and of good substance, the truss compact, and the colour a very pleasing soft blush tint. This is a really charming Hyacinth. Grandeur à Merveille is a better known variety of somewhat similar character with large bells and truss, cheap and useful. The remarkable examples of the new variety Jacques have been previously alluded to. One of these measured 10 inches by 4½, and though having the fault of being a little loose, it is without doubt a striking and effective Hyacinth.

Turning to the pink and rose section, we have in Gigantea a very handsome and useful variety, usually throwing a good spike under ordinary cultivation, and very fine for showing; it is also cheap. Noble par Mérite, pale pink, is one of the best of the doubles, having a more compact truss than the majority of them possess. Le Grand Concourant,

another double, resembles the last-named in hue. The truss is longer, but hardly so well furnished. Koh-i-Noor, rose, semi-double, is one of the best Hyacinths grown, having a beautifully symmetrical and well-furnished spike of bloom, though not of the largest size. Rubra maxima, soft pink, is another variety of considerable merit. Fabiola, light rose, deserves mention. Prince of Orange, bright pink, double, is a fine Hyacinth, with a very compact truss of medium size. Finally, there is Cardinal Wiseman, rose, a magnificent new variety, and a most valuable addition to the exhibition Hyacinths. It has a remarkably broad and dense truss, and is highly effective. The red, scarlet, and crimson section comprise some splendid varieties. Solfaterre is a warm glowing red with a medium-sized truss. Von Schiller is a grand red, with a deep stripe down the centre of each petal, the truss densely furnished, many examples measuring 8 inches by 4½. It is of dwarf, sturdy habit, and consistently good. Vuurbak, shining crimson, has a small but well-formed truss; and Roi des Belges is also somewhat small, though remarkably rich and striking in colour. Lord Macaulay, clear pale red, and Etna, bright red, are useful varieties.

The blues, dark and light, are very numerous. Perhaps the best of the former is King of the Blues, a really splendid Hyacinth with a perfectly formed and furnished truss. This variety can usually be recognised at a glance among many others by its beautifully moulded form. William III. is one of the very dark (nearly black) varieties, and may be classed as one of the best of them, Masterpiece and The Sultan also being good. There were some excellent specimens of the latter at Haarlem, the best measuring 8½ inches by 4½ inches. Marie is an old and useful dark blue, cheap and good. Laurens Koster, double, somewhat resembles King of the Blues in colour, and has a good truss. Lord Derby is one of the best of the light blues, the bells being large and the truss very broad, but somewhat short. Czar Peter is a very fine and useful variety. Queen of the Blues is a beautiful Hyacinth with a well furnished truss of medium size, clear pale blue. Pieneman has already been referred to. The spike is long and the bells of the largest size, but loose and drooping. Grand Maître is another large variety with a similar defect. Van Speyk, double, has a well formed truss. Two of the best yellows are Obélisque, with a long compact truss, and King of Yellows, closer, but hardly so good in colour. To this list of good varieties, by no means complete, yet affording material for a useful collection, must be added one differing in colour from them all, but equalled by few for beauty of form. Its name is Laura, the colour a soft rosy mauve, and the truss perfection as regards form and regularity.

A few words may advantageously be devoted to the Tulips. Happily for the honour of England a very different tale can be told of the comparative merits of these flowers. We are as far ahead of the Dutch in respect to Tulips as they are in front of us with Hyacinths. Evidently the peculiar wants of the former have not been studied so carefully as those of the latter at Haarlem. Good though many of the Dutch plants undoubtedly were, they were distinctly inferior to the fine specimens of Mr. Douglas at Regent's Park. The latter, though few, were splendid examples, being very dwarf and with remarkably large flowers. A great fault of the Dutch Tulips was that they were drawn, and the flowers consequently somewhat small. Mr. Douglas's plants were fully 6 inches dwarfer than the Dutch, and the flowers greatly exceeded them in size. Some of the best Tulips at Haarlem were exhibited by Messrs. F. & H. Van Waveren, and as they are only beginners at exhibiting they may be expected to show considerable improvement with more experience, especially as they hold very large stocks of bulbs.

The following are a selection of the best Tulips, commencing with the singles:—Cramoisie Pourpre is a beautiful rose-coloured variety resembling Proserpine, but brighter in colour and with smaller flowers. Royal Standard (silver), flaked crimson and white, and Royal Standard (gold), flaked scarlet and yellow, are both attractive varieties, the latter being very distinct. Rose Gris-de-lin, delicate rose suffused with white, is extremely pretty. L'Immaculée, pure white, tinged with lemon at the base, has medium-sized well-formed flowers, and ranks as one of the best. Keizer's Kroon is a well-known large variety, crimson, with broad bands of yellow, very cheap and useful. Ophir d'Or (Mon Trésor) is a magnificent Tulip, with very large rich yellow flowers, splendid for exhibition, far the best of all the yellows. This was finely shown at Haarlem. Nelly, pure white, with large flowers of good shape, is excellent, and very effective is the handsome rose variety Proserpine, one of the most popular Tulips grown. La Riente, medium-sized, well-formed flowers, base greyish, upper portion delicate rose, and Roi Pépin, crimson and white, somewhat small, are very attractive Tulips. Joost van Vondel, crimson flaked with white, is a large, handsome, and very useful variety, well known to most British growers. One of the most distinct of the numerous varieties exhibited at Haarlem was Pink Beauty, white, deeply suffused at the edges with pink, flower of medium size and excellent form. Delicatissima, white, was also pleasing. La Belle Alliance, rich crimson, is, though one of the oldest and cheapest varieties, likewise one of the most effective and useful. Joost van Vondel, white variety, is similar in form and size to the other. Queen of the Netherlands, which was honoured as a deserving novelty, is an exquisitely beautiful Tulip with very large flowers, white, with a faint blush tinge. It was exhibited by the well-known firm of M. Van Waveren and Sons. Bride of Haarlem, crimson flaked with white, and Rosa Mundi, blush flaked, are, though small, extremely pretty. Vermilion Brilliant, bright scarlet, is a very useful and popular Tulip. Wouwermaans, claret, and Van der Neer, deep mauve, are both large and of good form, and these are amongst the cheapest varieties. Last may be mentioned Chrysolora, a bright yellow of medium size.

One of the most beautiful of the doubles is Salvator Rosa, delicate rose, very pleasing in colour and handsome in form. Couronne d'Or, canary yellow, large and of excellent shape, is the best of its colour, though Tournesol Yellow is large and effective, the red and yellow form of the latter being also good. Purple Crown is very fine in colour, but the flowers are somewhat small. La Candeur, white, is a cheap, useful, and very effective variety. Murillo, white, tinged with rose, is attractive, and very useful is the late variety, Mariage de Ma Fille, white, feathered with crimson. Le Blason, rose, and Raphael, fine light rose, are the last two to be mentioned, the latter being one of the most beautiful of all double Tulips. Both the double and single varieties named, as also the Hyacinths, have been carefully selected from a very large number of varieties, and those wishing to have a good collection of these beautiful spring bulbs will not err by choosing from amongst them.—W. P. WRIGHT.

(To be continued.)

THE CARNATION.

[PRIZES for essays on the Carnation having been offered through the Ealing Gardeners' Improvement Society, Mr. Charles Turner, the adjudicator, awarded the first prize to the following useful contribution of Mr. David Cooper, foreman, Gunnersbury House, Acton.]

AMONG the multiplicity of flowers now under cultivation, whether for beauty or fragrance, I do not hesitate to say that the Carnation stands pre-eminent. The immense number and strong contrast of its different shades and colour, the rich green hue of its "grass," or foliage, the stately habit of its growth, and the sweetness of its perfume, afford attractions to all its admirers. Combined with the above sterling qualities, the usefulness of the blooms when in a cut state, either for adornment of the drawing-room, or for bouquets and buttonholes, or when grown in pots for the decoration of the conservatory and greenhouse, or as a bedding plant, it would not be wrong to say that it should be prominently placed in the first rank of all decorative flowering plants. The Carnation has a decided advantage over almost all other flowers—namely, the length of time it is in bloom, and the easy mode of cultivation in an ordinary way; also by special care and treatment and judicious selection of varieties it can be brought into bloom all the year round. Its popularity is unrivalled, for we should hardly find one garden where the Carnation is not grown.

It is said to have been first introduced into England from Italy, the date being questionable, and to have derived its name in the English language from its colour, pink, Carnation, or flesh colour. It was also called Clove Gilliflower, from its flowering in July, then known under the name of Caryophyllum, or walnut leaf (*folium nucis*), but why I am unable to say. The Carnation was also called Coronarium, from its having been used for the dressing of the head. It was afterwards given the appellation of *Dianthus*, *flos nobilis*, fine or superior flower, but is now termed *Dianthus Caryophyllus*.

CLASSIFICATION.

The Carnation is usually divided into several classes—namely, Flake, Bizarre, and Selfs, besides Picotees, which are generally classed by themselves, each having varieties of its own. Flakes are distinguished by their having a pure ground flaked with any one colour, as scarlet, purple, and pink flaked; Bizarre meaning a mixture of colour, and having more or not less than three distinct colours, and is known by which shade predominates, as scarlet, crimson, and purple bizarre. Selfs are characterised by being one decided colour, of which there are several sorts. Picotee signifies picked or spotted, hence they are distinguished by the colour of their edge. In addition to the above there are the well-known tree, or perpetual-flowering varieties, undoubtedly the most useful on account of their free and constant flowering propensities, and coming into bloom in the dull time of the year when other flowers are more scarce. This variety I intend to treat upon specially, but as I have also to deal with cultivation I will proceed with these few remarks to describe it to the best of my ability.

PROPAGATION.

This can be done either by layering (pipings or cuttings) or from seed. I will now commence with the latter—seed. If not inclined to save seed it can be easily obtained from any respectable seedsmen, but to insure a good strain it should be purchased from one who makes it a specialty. Propagating by seed is very interesting, as sometimes good and distinct varieties are secured, but there is always a certain amount of disappointment as regards worthless blooms. Seeds may be sown as soon as they are ripe or in April (the latter is preferable, as the young plants can be grown on and planted out straight away) in pans well-drained. The compost should consist of light rich loam and leaf mould passed through a sieve and well mixed with a good proportion of sand. Press it down moderately firm and level to within an inch of the top.

then give it a good soaking through a fine rose, which should be done a few hours previous to sowing to allow the soil to settle. If these and the following instructions are carried out more water will hardly be required until the seeds are germinated. Scatter the seeds evenly and just cover with a little of the soil; give it another slight sprinkle, cover the pan with a piece of glass, plunge into heat of about 65°, and shade from the sun. As soon as the seedlings appear they should be taken out and placed in a warm greenhouse or pit near the glass, where they will get sufficient heat to prevent their becoming drawn. As soon as they are large enough to handle prick them out into pans or boxes, carefully water and shade for a few days. In about a week or ten days they will have made a little root; then gradually harden off and place in a cold frame fully exposed to the sun with plenty of air; look after them for water, and on no account should they be allowed to get dry. When fairly established, or when they have made about six or seven leaves, plant them out into well prepared nursery beds, or trial beds I should call them, in a sheltered situation. Make the soil very fine on the surface and plant them about 10 inches apart, where they should remain until they have flowered, which will be the following June or July, when they should be carefully looked over and special varieties marked (should you be fortunate enough to secure any), and anything worth keeping might then be propagated, and all useless sorts pulled up and thrown away. In the winter when the weather is sharp they will require protection; nothing would be better than box frames and lights, not only to protect them from frosts, but to keep off snow and heavy rains, of which if they get too much, which is the case during the present season, they will be liable to a disease known as the spot. If frames and lights are not available a skeleton frame might be made over them with quartering of wood and mats or canvas used when necessary.

Cuttings.—This mode of propagation ought to be commenced as soon as they can be taken, which in ordinary seasons would be about the beginning of July, before they get too hard and woody from exposure to the scorching sun, which renders them less liable to root so readily as when in a more tender state. This would apply more to named varieties and those of which the quality of the blooms is certain, as doubtless some will not be sufficiently expanded to decide by the time mentioned above, and besides some are apt to run in colour, and in that case it would be better to leave these for the more certain method of propagating by layering them. When taking the cuttings care should be exercised by getting them where they appear too thick or too high up the stem where they could not be easily got at for layering, and not to damage or disfigure the plant just as it is coming into bloom. The most certain method of propagating by cuttings, I consider, is by making up a slight hotbed in a pit, or a half-spent one would answer as well, where another crop had been previously taken from. If using the latter remove all the old soil from the surface and cover the bed to a depth of about 4 or 5 inches with the following compost—One part of loam, one part leaf mould, and a little horse dung (not from old Mushroom beds, as it is liable to cause fungus), then add about one part of river or well washed road sand where obtainable, if not use silver sand, well mix the whole and pass it through a fine sieve. The soil should be far enough away from the glass to admit handlights, which should be placed close together so that the cuttings will be enclosed in two separate cases. If this method is adopted the chances of success will be much greater, as the air will be excluded to a greater extent, consequently less water and less shade will be required, and not so likely to damp off. Press the surface evenly and sprinkle with water through a fine rose, then insert the cuttings in rows pressed in firmly and about an inch deep not too close together, say, about 2 inches apart according to their size, then give a good watering to settle the soil about them. Put the outside lights on and shade, leaving a little air on until they are quite dry; be careful on this point, or they will be almost sure to damp off, then place the tops of the handlights on, keep close and not remove for a fortnight at least if they are thriving all right. In preparing the cuttings they should be cut horizontally with a sharp knife close below the joint, and the sheath that covers the joint should be carefully peeled off with the knife—not pulled off with the thumb and finger. Should the weather be very hot and dry the handlights may be sprinkled outside occasionally. Here I might say the shading used should be of some light material, and only used when the sun is out. After the above mentioned time the lights may be taken off sometimes of a morning, to dry the glass and see if any of the cuttings appear to be rotten, if so pull them up, but I do not think any danger need be apprehended on that score. In about six weeks they should be fairly well rooted, then the handlights might be dispensed with altogether. In another week afterwards they will be ready for potting into 60's, one or two

in a pot. Place them back in the same pit and keep rather close for a week or so, gradually allowing more air afterwards, when they might be removed outside and fully exposed to the sun until they are taken to their winter quarters.

(To be continued.)

EVENTS OF THE WEEK.—The second of the Shows at the Royal Aquarium, Westminster, will be held on Tuesday, April 29th, and will be chiefly devoted to Auriculas. The Executive Committee of the British Fruit Growers' Association will meet in the Horticultural Club Room, Hotel Windsor, Victoria Street, S.W., on Thursday, May 1st, at 5 P.M. The following are the chief of the Society meetings: The Royal on Thursday, April 24th, at 4.30 P.M.; the Quekett Club at 8 P.M. on Friday, April 25th; the Royal Botanic Society at 3.45 P.M. on April 26th; the Royal Geographical Society at 8.30 P.M. on Monday, April 28th; and the Society of Arts on Wednesday, April 30th, at 8 P.M.

— **THE WEATHER IN THE SOUTH** was unpleasantly characterised for several days at the end of last week by keen easterly winds which, in some cases, seem to have damaged the fruit blossom far more than the recent frosts. Friday was exceedingly cold for the time of year, but the wind changed to a westerly direction with a little rain and a slightly higher temperature. Pears are showing fairly well in some cases, in others there is not half a crop. Apples and Plums are not very promising according to reports from several districts.

— **THE WEATHER IN THE NORTH.**—April 14th to 21st. The week has been marked by prevailing easterly winds, a hard ungenial atmosphere; no frost except 2° on morning of 15th, and in the latter part but little sunshine. This morning, with slightly falling barometer, we have promise of a welcome shower. A fine "tid" has been got for Potato planting, and garden and farm work is satisfactorily forward in all departments.—B. D., *S. Perthshire*.

— **THE WILDSMITH MEMORIAL ORPHAN FUND.**—We are glad to state that by a subscription of two guineas by the Horticultural Club the whole amount required for the election of the Wildsmith Orphan has been raised.

— **SELAGINELLA EMILIANA.**—As a dwarf, compact growing, dense green plant for decorating purposes, such as to hide larger pots in the front of groups of plants, or as an edging in the stove or warm fernery, capital plants can be grown in 3 and 4-inch pots. This Selaginella grows about 6 inches high. The edges are crested, and altogether it is very attractive. By dividing the roots a large stock may quickly be obtained.—S.

— **THE COMMITTEE OF THE INHABITANTS OF FINSBURY SQUARE** have accepted a design by Crompton & Fawkes, Horticultural Builders of Chelmsford, for a pavilion for the centre of the square. The building will be 24 feet by 18 feet, and about 40 feet high, cruciform on plan with ornamental gables facing four ways, surmounted by an octagon lantern, in which a four dial clock will probably be placed at a future time. The base will be red rubbed brickwork, and the sides will be glazed for the remainder of the height. The roof will be covered by red tiles. It is contemplated that the building will be opened the first week in June. All the details have been designed by Mr. Fawkes.

— **THE HORTICULTURAL EXHIBITION AT BERLIN, APRIL 25TH-MAY 5TH.**—On Friday, April 25th, the great horticultural Exhibition at Berlin will be opened. It is said there will be a great quantity of fine plants and products from Germany, Belgium, the Netherlands, Italy, Austria, England, &c.; but especial features will be the architectural and art display. The chief purpose is to show how horticulture may be united with architecture and art, therefore decorated rooms, balconies, verandahs, staircases, &c., will be shown. Nearly 600 exhibitors have entered, who require 7200 square metres of space, 5600 of which are covered; 29,000 mark prizes, and many honorary and governmental prizes are offered. The Emperor, who is patron of the Horticultural Society of Prussia, has given a grand gold medal; the Minister

of Agriculture, Honorary President of the Exhibition, 500 marks. Science will be represented in its connection with horticultural practice.

— **THE BROCKHAM ROSE ASSOCIATION** have accepted the invitation of Robert Barclay, Esq., to hold their Show on July 2nd at Bury Hill, near Dorking.

— **FRUIT AS FOOD AND DRINK.**—The Secretary of the Vegetarian Society, Memorial Hall, Farringdon Street, London, E.C., desires us to state that deputations will be sent on application, to gardeners' meetings and horticultural societies free of charge, at which it may be desirable to discuss the subject.

— **GARDENING APPOINTMENTS.**—Mr. John Justice, foreman, Witley Court Gardens, has been appointed head gardener to J. S. Howitt, Esq., The Firs, Norton, Worcester. Mr. A. J. Long has left Westwood Park, Droitwich, where he was head gardener for five years, and has been engaged by J. Spiller, Esq., Compton House, Stockbridge, Hants.

— **RAILWAY CHARGES FOR VEGETABLES.**—This day I sent in a basket to London, via North Wall, three heads of Broccoli, for which I paid charges 5s. This seems such an enormous price for a basket of vegetables containing only three heads as stated. I have often been to Market Lane to dine, and the quantity would be partaken of by three ordinary feeders. Surely the charges are extraordinary.—W. BAYLOR HARTLAND, *Cork*.

— **ROSE CATALOGUE COMMENTARY.**—I am very much obliged to "A. C." for his too favourable mention of my paper, which I hardly thought deserved an elaborate peroration. I meant it to have appeared earlier, in time to assist novices in the selection of varieties, and fear that it would be of little use published separately. Lists of Roses become quite out of date in a year or two, as it is of the newer sorts especially that the average Rose-grower desires information.—W. R. RAILLEM.

— **THE schedule of the BRIGHTON AND SUSSEX HORTICULTURAL SOCIETY** (thirty-eighth season) is just to hand, and announces that Shows will be held on July 9th and 10th (Roses), and on September 10th and 11th. The Exhibitions will be held in the Royal Pavilion, Brighton, and in conjunction with the last named on September 11th, at 4 P.M., a Conference will be held by the British Fruit Growers' Association, Grapes and Tomatoes being the special features. Eighty classes are provided, numerous prizes being offered for fruits.

— **SWEET PEAS IN SPRING.**—I have sent you a few Sweet Pea flowers to show how the season of these useful flowering things may be prolonged. We cut the first on the 10th of March. The pink variety is the Princess Beatrice, which is in great demand, and will ultimately prove valuable for cutting purposes.—J. T. EBBUTT, *Winslade Gardens, Exeter*. [The flowers received were extremely fresh, bright, varied, and fragrant, and their usefulness at this season cannot be over-estimated. We shall be glad if Mr. Ebbutt will describe his method of culture.]

— **PROSPECTS OF FRUIT IN THE BOURNEMOUTH DISTRICT.**—The soil of Bournemouth is not very favourable to the production of fruit, but some fair samples are grown in the neighbourhood. There is a fair amount of blossom on Cherries, Pears, and Apples, but on Plums it is scarce. Some of the trees are well covered, but the birds have been very destructive. The following are a few sorts which are showing best:—Pears, Jargone'lle, Beurré d'Amanlis, Marie Louise, Louise Bonne of Jersey, and Williams' Bon Chrétien; Apples, Ribston Pippin, King of the Pippins, Cocker's Pippin, Keswick Codlin, and Hawthornden. Small fruits are looking well.

— **VEGETATION GENERALLY.**—We have experienced a long spell of dry weather with north-east and easterly winds, and Euonymus which grows with us all winter have suffered in exposed places. A welcome change took place on April 15th—warm showers and rain all day Thursday. The beautiful pink Ribes will soon be over, but shrubberies are gay with Berberies. Forsythia viridissima, the white Andromedas, Laurustinus, Tulips, Wallflowers, Aubrietias, Arabis, Pansies, Polyanthus, and Myosotis are flowering well in the borders. Grass is growing freely, and the scythe and machines have been at work for some time.—J. B. S.

— **TWO GOOD OUTDOOR HYACINTHS.**—A Hyacinth seldom cultivated out of doors, yet most suitable for the purpose, is Grand Lilas, single-flowered, porcelain-lilac—an uncommon colour, and the spikes of bloom are almost self-supporting, a great point in the favour of this variety. We have it planted in the front of Rose borders and upon the

grass, in clumps of about five bulbs each. Another good variety is the pure white double flowered La Tour d'Auvergne. Seven years ago we planted in the herbaceous borders the bulbs which had previously flowered in pots. Every year since they have flowered well, and are as good this year as they were the first season in pots. I might also say that our soil is cold and wet in the winter, consequently not the most favourable for bulb culture. Beyond taking up the bulbs once when the border was trenched two years ago, they have not been disturbed.—E. M.

— **NARCISSUS BULBOCODIUM.**—Those who have not grown this yellow Hoop Petticoat Narcissus in pots would do well to procure a few bulbs, in the autumn potting half a dozen in a 4-inch pot, giving them the usual bulb treatment, and at this time next year reap the reward of the slight outlay in the possession of rich masses of yellow flowers which will be produced. For the front of the stages in the conservatory or as edgings to groups in any other structure, arranged on a base of small Maidenhair Ferns or Selaginella Kraussiana, the golden flowers show to the greatest advantage for cutting; intermixed with its own foliage in small vases a pleasing effect is produced.—E.

— **WHERE** ordinary varieties of HIPPEASTRUMS (AMARYLLISES) are simply grown for decorative work greater success may be obtained by allowing the bulbs to stay in the same pots for two or three years, or even four sometimes, without potting, than by annually disturbing their roots, which I know is the general plan of cultivation. Where 8 and 9-inch pots are employed the offsets, through not being disturbed or separated from the parent bulb, will throw up flower spikes. When plants in the pots named develop from two to half a dozen flower heads, such are valuable for conservatory or house decoration, giving a display of brightly coloured flowers, which contrast so well with white flowers such as Lilies, Spiraeas and Deutzias. One point in their cultivation is not to allow the roots to be dried too much. The foliage should never be allowed to wither. Those plants which carry some green leaves all through the winter succeed the best. Liberal feeding when growth is active is the main point to consider. Nothing is better than liquid manure from the cowhouse.—M.

— **A CAPITAL** plant is CHOISYA TERNATA for covering a bare wall in a cool house, or it will succeed in the south of England planted at the base of a south wall. In such a position it flowers amazingly where the growth is not allowed to become so thick as to prevent the shoots being thoroughly ripened. The flowers are somewhat like Orange flowers in their individual form. The perfume is pleasant without being too powerful. The foliage is particularly a glossy dark green, and when bruised with the hand emits an agreeable perfume. The leaves are often used instead of Fern fronds for the cut flower vases, and they last fresh some time. Cuttings strike readily if taken with a heel any time when the new growth is nearly ripened. A sandy soil, gentle bottom heat, and shade from bright sun are all that are needed to ensure success; the plants quickly grow into a good size. The roots at all times must be kept moist. While growth is being made abundance of water must be supplied both to the roots and over the foliage, or red spider will gain a hold.—S. P.

— **THE SPARROW PEST.**—I am afraid your correspondent "B." will only be wasting valuable time, and running a great risk of killing something he does not wish to lose, in trying to poison sparrows and other birds when they have attained to such numbers as to become a pest, which is no doubt the case in many places, especially near the homes of some of our great game preservers. The proper remedy is not far to seek, and to find it out we must look for the cause of the pest. Nature herself provides the requisite balance in all things, and if left to herself will not for any length of time trouble us with a pest, even of sparrows. The cause of the smaller birds increasing at such a rapid rate is the wanton manner in which gamekeepers and others shoot or otherwise destroy the hawk and the cuckoo and similar birds which prey either upon the eggs or bodies of the smaller birds, and thus Nature is deprived of the means most wisely provided for keeping down the numbers of those birds, which would otherwise increase too rapidly. The worst part of the matter is that such a course is purely a one-sided business, for whoever hear of the squire or nobleman who directs his gamekeeper to kill the larger birds of prey having any thought for the loss he is thus causing to the poor farmer or gardener from the absence of those birds of prey, which are actually the greatest protectors of his crops? All animal, bird, or insect pests may be traced more or less to the absence of their natural enemies, and if they can only be provided in sufficient numbers there is never any doubt as to what the result will

be. Would Australia have been visited with a rabbit pest if a couple of healthy weasels had been imported with the first few couples of rabbits?—A. T. MARSTON.

— THE fortnightly meeting of the BOURNEMOUTH GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION was held on Wednesday, April 16th. Mr. G. Peel, gardener, Studley, occupied the chair, and there was a good attendance of the members to hear Mr. J. B. Stevenson, the Secretary, read his paper entitled, "Notes on a Trip to Jersey." The reader briefly described the trip across the Channel, and also some of the most interesting places visited, notably the famed Bagot Vineyard of Mr. Bashford, where there are upwards of three miles of glass houses erected for the cultivation of Grapes, Tomatoes, Melons, and early Potatoes. The mode of producing young Vines for planting in the houses was described, and in referring to the skill of the Jersey Grape thinners, he mentioned that one man thinned a house of Black Hamburg Grapes in two and a quarter days, the crop weighing about 800 lbs., also a house of Gros Colmans, weighing between 600 and 700 lbs. in the same time; also in a contest where three men respectively thinned 365, 360, and 349 bunches each, the variety being Gros Colman, and the bunches averaging 1½ lb. each. Humorous reference was made to the great number of Jersey Cabbages, and it was mentioned that for a prize watch a Cabbage over 20 feet long was shown, and the reader produced for the members' inspection one about 10 feet long just coming into flower. Mr. Stevenson received a hearty vote of thanks for his paper. Mr. Ward, gardener, Kempsey, showed a specimen Gloxinia, and a fine plant of *Dendrobium thyrsiflorum*; and Mr. Share, gardener, Higham, some excellent Calceolarias. A hearty vote of thanks to the Chairman concluded the meeting.

— ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this Society was held on Wednesday evening, the 16th instant, at the Institution of Civil Engineers, 25, Great George Street, Westminster; Mr. Baldwin Latham, F.G.S., President, in the chair. The Marquis of Gallidoro and J. M. Veevers were elected Fellows of the Society. The following papers were read:—1, "The Cold Period at the Beginning of March, 1890," by Mr. C. Harding, F.R.Met.Soc. At the commencement of the month a rather heavy fall of snow was experienced in many parts of England, and very cold weather set in over the midland, eastern, and southern districts, the temperature on the 3rd and 4th falling to a lower point than at any in the previous winter. The lowest authentic thermometer readings, in approved screens, were 5° at Beddington, 6° at Kenley in Surrey and Hillington in Norfolk, 7° at Chelmsford and Beckenham, 8° at Addiscombe, 9° at Reigate and Brockham, and 10° in many part of Kent and Surrey. At Greenwich Observatory the thermometer registered 13°, which has only once been equalled in March during the last hundred years, the same reading having occurred on March 14th, 1845. During the last half century the temperature in March has only previously fallen below 20° in three years, whilst during the whole winter so low a temperature has only occurred in eight years. 2, "Note on the Whirlwind which Occurred at Fulford, near York, March 8th, 1890," by Mr. J. E. Clark, B.A., B.Sc. A sharp and heavy thunderstorm occurred at York about 2.30 p.m. At the same time, or shortly afterwards, a whirlwind passed a little to the south of the city from Bishopthorpe to Heslington, a distance of about four miles, its width varying from 3 or 4 to 250 yards. The author made a careful survey of the track of the whirlwind, and described the damage done by it to trees, buildings, &c. 3, "On the Possibility of Forecasting the Weather by Means of Monthly Averages," by Mr. A. E. Watson, B.A., F.R.Met.Soc. The author is of opinion that the average values of meteorological phenomena are constant quantities, and that any variation from them is sure to be met by a compensating variation in the opposite direction.

THE PROPOSED HALL OF HORTICULTURE.

A FEW weeks ago circulars were issued to nurserymen and others engaged in business connected with horticulture inviting their attendance at a meeting and their co-operation in raising the necessary amount of money for the purpose indicated. The meeting was held in the Council room of the Royal Horticultural Society on Tuesday last, the President, Sir Trevor Lawrence, Bart., M.P., in the chair.

THE PRESIDENT in opening the proceedings said, considering the large number of invitations posted he had hoped to see a more crowded meeting. As had been many times stated the present arrangements for holding the shows and meetings of the Society were temporary, and he freely admitted unsatisfactory. He believed that if the Show then being held in the Drill Hall were in a suitable building in a central position the public of London would flock to admire it. A central hall

had become a necessity, and one favourably situated would be appreciated by amateurs and prove of benefit to the trade in which many present were engaged. It was thought, and still hoped, that the project would be taken up by the trade and carried to a successful issue. He feared it was not fully understood. No money was asked to be given, but only lent for a time, with its ultimate and certain repayment. The names of the subscribers he thought guaranteed the stability of the undertaking, and not the Royal Horticultural Society but the trustees would be responsible for the repayments. They wanted a thoroughly satisfactory building in a commanding position, and he felt that with the earnest co-operation of all interested in horticulture the most desirable object would be achieved.

BARON SCHRÖDER, on rising, thanked those present for their attendance, which was not, however, so large as he wished to see. There were two main points to consider—first, the monetary; second, the site for operations. In respect to the former, the Royal Horticultural Society was incapable of extricating itself from the present hall, which, for the purpose of exhibitions, he could only compare to a dust-bin; but if horticulturists would join him, they might have a hall worthy of the Society and of horticulture. He did not ask for any money as a gift, nor for the payment of any money even as a loan till £40,000 were promised. He only asked the public, including the trade, to have confidence in the trustees, and offer to lend money for a time, and the greater the amount the quicker would be the repayments. It was a sound, genuine financial transaction, or it would not have his countenance and support. Amongst his friends who were not pecuniarily interested he had got promises of £6000. As soon as he explained the scheme to the Duke of Westminster he at once perceived its safety, and that it was of national importance, and immediately wrote himself down for £1000. That might reassure all who had any lurking doubt as to the thorough soundness of the principles on which they were acting. The best site for the hall was the Thames Embankment. It was an important public highway, and floral exhibitions there would be largely attended. Persons pent up in rooms and offices longed for the relief that flowers and gardens afforded. He believed that with a suitable building the income of the Society would be doubled, and a recognised centre for horticulturists and their products would be bound to give a great impetus to trade. The hall would not be for the Royal Horticultural Society alone, but would be of service to other societies associated therewith. In connection with the building he would like to see a permanent exhibition of implements, seeds, shrubs, &c., and supporters would have claims for positions. But he desired to say plainly that the requisite sum could not be had unless the trade joined heartily in the endeavour to obtain a good portion among themselves, their friends, and customers. When the plan was understood he believed many would give their help gladly. Then the question arose as to how lenders would get their money back. Bonds would be given for every penny, to be drawn annually, the Royal Horticultural Society having no power to interfere, the trustees being solely responsible; and a suitable site and building being obtained they would return the money in full to the lenders. Then, when all had been paid, the hall would belong to the Society, in which, he said, a good deal of life remained, and if better circumstanced it would increase in activity, do more in the promotion of horticulture, give advice on all subjects within its sphere, and become what it ought to be, a power in the country. The scheme was now before them, and he wanted them to feel as he felt, that it would be a disgrace for them to die without providing a hall of horticulture.

MR. W. BULL, in rising to propose a resolution, said they as horticulturists were certainly in an anomalous position, for in no country in Europe was gardening so well and extensively practised, yet in the first city in Europe they had no suitable place in which their work could be represented. A hall would enlist wider sympathy with their work and gain new supporters. He appealed to all to help on towards accomplishing the object in view, but without the cordial assistance of the trade the scheme would fail. He moved a resolution to the following effect:—"That the representatives of the trade here present cordially approve of the scheme, and pledge themselves to support it."

MR. BUNYARD, as a country nurseryman, seconded, and took occasion to ask if the whole of the £40,000 was not forthcoming, if a lesser sum could not be applied in providing such a building as the means would allow?

BARON SCHRÖDER gave an emphatic "no" to the proposition, and said it would be a great mistake to start with any less sum. If he got £50,000 all the better, and he could pay it back sooner. All might perhaps not quite understand that, but it was a fact; he would have nothing to do with unsound finance, and would rather abandon the scheme than "fiddle about" with money.

MR. GEORGE PAUL said he did not understand the scheme at first; indeed, it nearly took his breath away. But he understood it now, and saw it was sound and good. It was not for the Royal Horticultural Society alone, but such a building as they hoped to provide would be available for the transaction of the business of the Gardeners' Royal Benevolent Institution, the Gardeners' Orphan Fund, trade meetings, and all agencies connected with gardening; and he thought the trade might induce their friends and customers to help forward the movement materially.

MR. BRUCE FINDLAY believed the movement would end successfully because Baron Schröder was at the head of it. The effort was laudable, and he should have pleasure in doing all he could for it in the Manchester district. Place it on broad grounds of public service for

the public benefit, and the money ought to be forthcoming before the end of the year; for what, he asked, is a loan of £40,000 among so many?

MR. SHERWOOD said they could not too fully make known the real nature of the scheme. When he mentioned it to a friend he was offered a gift of £5, but when he explained it was not a gift that he sought, but a loan, his friend at once put down his name for £50.

The proceedings were animated throughout, the speakers frequently applauded, the resolution passed unanimously, and a Committee, composed mainly of provincial nurserymen and seedsmen, appointed to carry it out. The nomination of the Committee was proposed by Mr. H. Williams, and seconded by Mr. J. Cheal.

the late Dr. Horner, F.R.S., of Hull, also an ardent florist. He practised there for many years as a physician, and rose to high eminence in his profession, but always found time from his arduous duties to cultivate the Tulip, Auricula, Pink, Carnation, Ranunculus, &c., to lecture on botany, and write interesting articles for the gardening papers and magazines. The Rev. F. D. Horner was born in the same year as myself, 1837, but a few months earlier, on the day of the Carnation Show. In his early years, when a mere boy, he used to attend the flower shows with his father, and he has told us that Tulips and Auriculas took the place of the usual playthings

FIG. 50.—THE REV. F. D. HORNER.

THE REV. F. D. HORNER.

[WE have great pleasure in publishing the portrait, from a recent photograph, of this earnest, genial, and successful florist. He may be fairly regarded as the premier raiser and cultivator of Auriculas, and the moment seems opportune for the representation. The following appropriate references by Mr. Horner's friend and fellow-worker in the cause of floriculture will be acceptable to our readers.]

The Rev. F. D. Horner, whose portrait is published in the present number, is well fitted to be a leader of floriculture. He is a son of

of boys of his age, and he cannot remember the time when he had not some share in aiding his father to cultivate the floral treasures of that notable garden in Hull. Dr. Horner had also in his garden a choice collection of Cacti, Echinocacti, and other curious succulent plants; and thus there grew in the mind of our friend, with the love of Auriculas and Tulips, a longing to cultivate the quaint and curious productions of Nature. The time came for Mr. Horner to leave the home of his early years. He held various curacies in Yorkshire, and also for a short time in Liverpool, but never at any time losing his

regard for his favourite flowers. In 1870 he went as curate in charge of Kirkby Malzeard, a small country village about four or five miles from Ripon, and there I visited him for the first time in 1876. At that time a choice collection of Auriculas had been formed, also the choicest kinds of Tulips, Ranunculuses, Carnations, and other florists' flowers; the quaint and curious productions of Nature being there also; tubs and home-made tanks of various kinds being filled with water plants, a source of never-failing pleasure and instruction to their owner. He could truly say of his numerous garden treasures—

"My never-failing friends are they,
With whom I converse night and day."

The Auricula was the favourite flower; this could easily be seen. They had the best position in the garden, and the first place in the heart of the owner. All the finest varieties had been obtained. Mr. Campbell had raised Lord of Lorne and Duke of Argyle. Prince of Greens (Trail) was also in the collection, and another fine flower, William Lightbody, was superior to Lord Clyde of the same colour. Freedom (Booth), Colonel Taylor (Leigh), and Champion (Page) were the best green edges. George Lightbody (Headley) and Lancashire Hero (Lancashire) were the best grey edged flowers. In white edges I noted Smiling Beauty (Heap) and John Simonite (Walker) as far and away the best, but room was also found for Miss Arkley (McDonald), Earl Grosvenor (Lee), and even Ann Smith (Smith). In selfs, besides those named above, Pizarro (Campbell) was placed by Mr. Horner highest on the list. There were 600 named plants, and at least 2000 seedlings, but not many had flowered. Those that had done so were in many instances, as Mr. Horner expressed it, "amusing in their absurdity" their vagaries were remarkable. The fine white edged Smiling Beauty gave crimson and maroon selfs good for nothing. The pretty little quaker-like Ashworth's Regular gave fringed selfs like Sim's Vulcan. Even the poor green edged thing Highland Laddie was pressed in as a seed bearer, and produced goggle eyed dark selfs; but a good start was made, a few good things were found amongst the two thousand, and the work went on apace.

In the year 1881 I was again at Kirkby Malzeard, and could compare the plants I saw in that year with those in 1876, and what a change! Seedlings raised in the garden had ousted nearly all the old favourites of long ago. The only two really thought to be worth keeping were Lancashire Hero and George Lightbody. Heroine, a grand dark self, had been raised and went at once to the top of the list. The lovely blue self Sapphire was also plentiful. The green, grey, and white edged classes had also been improved, but the best of them have been annually exhibited in London at the national shows, and duly recorded in the *Journal of Horticulture*, when the first prize collections have been described. Now a larger and wider field has been opened, and at Lowfields, Burton-in-Lonsdale, thousands of seedling Auriculas are yet raised and proved year after year; and as we have recently read in the pages of the *Journal of Horticulture* Orchids have been added to the attractions of the florists' garden. In the culture of these I may say that Mr. Horner is ably seconded by Mrs. Horner; but indeed if the truth may be told the lady is first here, and it really ought to read that Mrs. Horner is ably seconded by her husband. There are no elaborately planned and expensively built houses, nor highly trained cultivators to attend to the wants of the occupants, but the results obtained would be creditable in the best conducted establishments.

The Auriculas and Tulips are not forgotten. Some remarkable varieties of the Tulips have been raised from seeds. Some, yet in the breeder state, are remarkable for form, purity, and brilliancy of colour; others in the rectified state are bound to take a high position when compared with the best yet produced. Seedling Orchids are also being produced in this quiet country garden, and those who find time hang heavy on their hands in the country would do well to remember that "the garden is the purest of human pleasures," and that time in the country may always be pleasantly and profitably occupied by the rearing of fruits, flowers, or vegetables. It is certainly the healthiest of all occupations. The lover of gardening is brought face to face with Nature, so to speak, and rightly interpreted the student of Nature must be made happier and better in his daily life. The many admirers of our friend, and who are also readers of the *Journal*, will be pleased to see his portrait, and all of us sincerely hope that both Mr. and Mrs. Horner may long be spared to continue the work so well begun, and that the garden at Lowfields may ever continue to be as it is now—an illustration of how much may be done by a moderate outlay well applied; but the greatest good such a garden can accomplish would be as an object lesson to country gentlemen and ladies with spare hours at their disposal. It shows them a good way of redeeming the time,

and also, which is of infinite importance to us as true-born Britons, those who engage in such work are aiding to an extent not measurable at present in raising the position of our common country amongst the nations of the world.—J. DOUGLAS.

NATIONAL AURICULA AND PRIMULA SOCIETY.

APRIL 22ND.

THOUGH it cannot be said that Auriculas extend rapidly in popular favour, or that the number of exhibitors increases in proportion to other show flowers, yet all admirers of the florists' types admit that the flowers possess a delicacy and refinement of beauty scarcely surpassed in others. The fine distinction between the show varieties render a close study necessary to appreciate them, and the "properties," from a florist's point of view, are not so apparent at first glance as in the case of many other flowers seen at exhibitions, consequently they do not appeal to the public with the same force as Roses or Chrysanthemums, or even Carnations. Still Auriculas have some qualities that all can understand, and these are perhaps more notably developed in the selfs and Alpines, in which rich shades of colour are supported in their claims for attention by a delightful fragrance, a primrose perfume, concentrated and enriched. As garden plants the Alpine Auriculas will always share with the Primroses and Polyanthus a deserved popularity for being easily grown, and amongst the earliest occupants of borders they are useful in no ordinary degree.

The Auricula Society did well when they amended their title so as to include Primulas, and though only a very small portion of the schedule is devoted to these charming plants, there is every probability that it will be found necessary to increase the encouragement provided for them. So many early flowering Primulas of much beauty are now grown, and becoming greater favourites every year, that a few more classes devoted to them would be likely to induce fresh exhibitors to enter.

The Society's Show of this year was held, in conjunction with the Royal Horticultural Society's Committee meetings, in the Drill Hall, James Street, Westminster, on Tuesday last, but the Hall is not one of the best places for a Show of this character, the deficiency of light being a serious defect where such minute characters have to be observed. With this exception there was little occasion to complain, for the plants were arranged upon the tables in the centre and at the side of the hall, and thus admitted of a ready inspection by the visitors; but there appeared to be some delay and confusion with the prize cards, and the winners in some classes could not be recorded with accuracy, therefore are omitted. In numbers the exhibition was probably the best yet held, as there were 139 entries. The quality was also generally satisfactory, though there were examples of roughness in some collections. Turning to the schedule, we will take the classes in the order of arrangement there, briefly noting the names of the successful competitors and of the best varieties shown.

SHOW AURICULAS.

Nine classes were appropriated to these, with six prizes in each, and the entries constituted a large portion of the Exhibition. All the leading green, grey, and white-edged varieties were there, together with the selfs and some seedlings, and they were examined and criticised by the experts with all the enthusiasm that florists can bring to bear upon their hobbies.

The leading class was that for twelve distinct varieties, which invariably affords the chief interest, and on this occasion there were four exhibitors, the premier award being secured by the Rev. F. D. Horner with strong plants of the following varieties:—Favourite, eight pips; Snowdrift, six pips; Laura, eight pips; Simonite's F. D. Horner, eight pips, a grand plant, the premier Auricula; Melainie, eight pips; Woodhead's Rachel, eight pips; Atalanta, four pips; Magpie, eight pips; Monarch, five pips; Desdemona, five pips; Iris, eight pips; and Headly's George Lightbody, five pips; all the others being Mr. Horner's own seedlings. The second prize was taken by Mr. T. E. Henwood, Hamilton Road, Reading, who had good plants. Woodhead's George Rudd had eleven pips, and some of the others were also large. Mr. J. Douglas, Great Gearies Gardens, Ilford, was third with an admirable collection; and Mr. A. J. Sanders, gardener to Viscountess Chewton, Bookham Lodge, Cobham, Surrey, was fourth.

With six varieties several competitors entered, and the prizes were adjudged as follows:—First to Mr. T. G. Henwood for Headly's George Lightbody, Mellor's Reliance, Woodhead's Mrs. Dodwell, Horner's Heroine, Barlow's Mrs. Potts, and Simonite's F. D. Horner. Messrs. Douglas, Horner, and Sanders were second, third, and fourth in the order named.

Four varieties were shown by ten exhibitors, Messrs. C. Phillips, Reading; G. M. Wheelwright, Reading; W. Badcock, Reading; C. Walker, Reading; and P. J. Worsley, Clifton, in the order named; and two varieties by Messrs. Phillips, Wheelwright, G. Barlow, Manchester; Walker, Badcock, and J. Worsley.

The single specimens constitute a large class, and at the Show under notice about fifty plants were entered, but there is always much difficulty in placing the whole of the twenty-four prizewinning plants in their correct order, and we can only give the names of the varieties. The names of the exhibitors were not obtainable.

Green-edged.—First, Horner's Emerald; second, Leigh's Colonel Taylor; third, Lancashire Hero; fourth, Horner's Monarch; fifth,

Simonite's F. D. Horner; sixth, no name; seventh, Horner's Monarch; eighth, Simonite's Talisman.

Grey-edged.—First, Mabel; second, G. Lightbody; third, Richard Headly; fourth, Lancashire Hero; fifth, G. Lightbody; sixth, Marmion; seventh, unnamed; eighth, Richard Headly.

White-edged.—First and second, Conservative; third and fourth, Read's Acme; fifth, Walker's John Simonite; sixth and seventh, Acme; eighth, Conservative.

Sels.—First, Mrs. Potts; second and third, Heroine; fourth, Black Bess; fifth, C. J. Perry; sixth and seventh, Black Bess; eighth, Topsy.

In the large class for fifty plants, not less than twenty varieties (including Alpines) it is seldom that much competition is induced. On Tuesday two entered, and the prizes went to Mr. J. Douglas for an excellent collection, chiefly show and self varieties, Mr. C. Turner being second with Alpines and some show and self varieties, all the plants were extremely healthy.

ALPINE AURICULAS.

In this section the classes are arranged in similar order to those for show Auriculas, and to the uneducated in the florists' code they appeared to be the most beautiful. As regards effectiveness from a decorative point of view there can be no question about their superiority if the sels in the other group are excepted. With twelve varieties the following exhibitors were successful:—Mr. Henwood first with an excellent dozen, comprising Chas. Turner, Defiance, Mrs. Martin, seedling, Edith, Philip Frost, Love Bird, Homer, Mongo McGeorge, Sunrise, Miss Blackburn, and Mary Francis, deep purple crimson, shaded centre (first class certificate). Mr. C. Turner was second, Mr. Douglas third, with Mr. Cragg, Crouch End, fourth. The best six came from Mr. Phillips, Reading, showy and well flowered plants. Mr. Douglas was second with smaller plants, Mr. Wheelwright third, and Mr. C. Turner fourth. Ferns were shown by Messrs. Wheelwright, Phillips, Walker, Kerr, and R. Dean.

Single Specimens (Gold centre).—First, Mr. Henwood with William Comber. Second, Mr. J. F. Kerr with J. J. Colman. Third, Mr. Wheelwright with Hotspur. Fourth, Mr. Turner with Sunrise; and fifth, Mr. Henwood with Miss Moon. (White or Cream Centre).—First, Mr. Turner with Miss Rae. Second, Mr. Henwood with a seedling. Third, unnamed. Fourth, Mr. Turner with Symmetry; and fifth with Tennyson.

POLYANTHUSES.

Notwithstanding the attractions of the handsome gold-laced Polyanthuses, they are never largely represented at the southern shows. They seem to be avoided for some reason by cultivators. Only three classes were appropriated to them, and the entries were not sufficiently numerous to make a large display. For six varieties the premier award was gained by Mr. S. Barlow, who had neat plants of John Bright, Cheshire Favourite, Lancer, Cox's Prince Regent, Exile, and George IV. Mr. R. Dean took the second place with several seedlings and Sir Sidney Smith; and Mr. J. Douglas was third. The best three were shown by Mr. S. Barlow, the varieties being George IV., Exile, and Cheshire Favourite. Messrs. J. Douglas and R. Dean were second and third. Single specimens of Cheshire Favourite, Cox's Prince Regent, Sir S. Smith, and John Bright gained the prizes for Messrs. Barlow and J. Douglas in the order named.

EXTRA CLASSES.

Fancy varieties of Auriculas, Polyanthuses, and Primroses formed the chief features. Of these classes but two were devoted to Primulas, one for a basket of Primroses, and eight prizes were offered for seedlings. In the class for twelve Fancy Auriculas the awards were secured by Mr. J. Douglas, first, with seedlings of a distinct character; Mr. G. Barlow was second, and Mr. R. Dean third. With a similar number of Fancy Polyanthuses Mr. R. Dean secured first honours for large plants well flowered; Mr. J. Douglas was second, and Mr. W. Harper, Guildford, was third, all very bright and pleasing. Single Primroses came from Mr. R. Dean, who was first for excellent varieties and plants; Mr. J. Douglas was second, and Mr. Harper third.

The Primula classes were for twelve and six respectively, and the exhibitors were Mr. Douglas, who had P. verticillata, P. oboeonica, P. nivea, and P. hortusoides varieties. Mr. W. Harper was second with smaller plants, and O. T. Hodges, Esq., Lachine, Chislehurst, third. For six Primulas Mr. G. Barlow was first, P. oboeonica being the most notable plant. Mr. R. Dean was second, a yellow duplex Primula being the best. Mr. R. Dean had the first prize for a basket of Primroses; Messrs. Paul & Son were second, and Mr. Harper third, the two former having very effective displays.

Seedling Auriculas.—In the white-edge class the first prize was awarded for *Miranda* (Horner), a neat flower of moderate size and good shape, narrow black body colour, clear edge, well defined thick paste, and rich tube. The second prize went to *Snowdrift* (Horner), a large flower, with broad deep maroon body colour, good paste, but somewhat pale tube. In the class for sels the prize was accorded to *Buttercup* (Horner), a bright yellow self, with pure white well defined but narrow paste. A very distinct and pretty variety. The second prize was awarded to *Dimple* (Horner), a deep purplish crimson self, with pure white dense paste; a well-formed handsome flower.

A first-class certificate was awarded to the following:

Jenny (Mr. T. S. Hedderley, Buleote, Notts).—A beautiful shaded Alpine, with rich velvety maroon body colour, and a gold centre. Flower large, and well proportioned.

The National Auricula Society may be congratulated upon the dis-

tinued advance in the number of competitors at this Show, but we cannot extend the congratulation to officials concerned with the management of the Exhibition. In this respect it has always been peculiar, and the present occasion was no exception to the rule. Until late in the afternoon it was impossible to ascertain who were the successful competitors in several of the classes, and in the single specimen classes the confusion was still worse. It is strange that some better system has not been adopted after so many years of experience in the matter.

ROYAL HORTICULTURAL SOCIETY.

APRIL 22ND.

TUESDAY was a busy day at the Society's headquarters, both in the Drill Hall, James Street, Westminster, and in the Lindley Library. Besides the attractions provided for the Fruit, Floral, and Orchid Committees there was an excellent Show by the members of the National Auricula Society, and the result was that the whole available space in the hall was occupied, four rows of tables extending the entire length of the building. This, however, was not the only satisfactory matter, for the attendance of visitors was much larger than on any previous occasion, and for the first time the hall was really crowded

FIG. 51.—NARCISSUS INCOMPARABILIS QUEEN SOPHIA (see page 338).

during the afternoon, amongst those present being the Baroness Burdett Coutts and the Rt. Hon. J. Chamberlain, M.P.

Then at 1.30 P.M. the meeting of members of the horticultural trade to consider and support the Horticultural Hall scheme was held in the Lindley Library, and the deliberations there occupied over an hour. Following closely upon this was the general meeting at 3 P.M., when the Veitch Memorial medals were presented to Messrs. David Thomson and Bruce Findlay, and a paper was read by the Rev. Wolley Dod on Primulas. All this business crowded into the space of one afternoon afforded abundant occupation for those immediately concerned. It was a highly successful meeting, and the appearance of activity was most welcome.

FRUIT COMMITTEE.—Present: Sir C. W. Strickland, Bart., in the chair, and Messrs. D. Thomson, J. T. Saltmarsh, P. Crowley, R. D. Blackmore, T. F. Rivers, G. Cliffe, J. Cheal, G. W. Cummins, A. H. Pearson, G. Bunyard, J. Smith, G. Wythes, J. Hudson, F. Q. Lane, H. Balderson, A. Watkins, and J. Wright. Mr. J. Baylor Hartland, Cork, sent very large heads of his new Broccoli, April Queen, but though large, the heads were very compact, and the Committee recommended that the variety be grown at Chiswick. Mr. F. Q. Lane sent fruits of Lane's Prince Albert Apple for showing its keeping properties. They were firm and in good condition. A vote of thanks was accorded. Mr. G. Wythes sent excellent fruits of a Strawberry described as a seedling from Keen's Seedling, raised by the late Mr. Woodbridge, with a plant in bearing; also one with fruits of the parent variety. The Committee were unanimously of opinion that this was not the true Keen's Seedling,

which the dwarfed and earlier new variety more closely resembled. A cultural commendation was recommended for the fruits.

Messrs. J. Cheal & Sons exhibited excellent and admirably kept samples of a number of Apples, among which the following were particularly noteworthy—Brabant Bellefleur (large), Norfolk Beefing, Norfolk Bearer, Alfriston, Wormsley Pippin, Dumelow's Seedling, Ribston Pippin, Hornead Pearmain (very good), Lane's Prince Albert (fine), Brownlee's Russet (excellent), and Dutch Mignonne. A silver Banksian medal was recommended for the collection. The Committee recommended for the consideration of the Council the question of holding an exhibition of jams and jellies of different fruits, also dried, bottled, and other preparations of British fruits, towards the end of October.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair, and Messrs. Shirley Hibberd, H. Herbst, Bruce Findlay, E. Molyneux, James Walker, F. W. Burbridge, F. Ross, W. C. Leach, H. B. May, C. T. Druery, T. Baines, C. Noble, H. Cannell, G. Paul, J. Fraser, H. Turner, W. Holmes, G. Nicholson, and Rev. H. H. D'Ombraim.

Messrs. Ryder & Son, Sale, Manchester, contributed an exceedingly interesting group of *Primula cortusoides*. Nearly fifty large pans of plants were staged in a great many varieties. Some of the best were Mrs. Geggie, purple; Rosy Morn, pale rose; Ruby Queen, rosy crimson; Queen of Whites, pure white; Harry Leigh, mauve; Miss Nellie Barnard, deep crimson, much frimbriated; Delicata, pale mauve; Bruce Findlay, bluish mauve, and Mrs. Ryder, delicate blush. Mr. J. Walker, Thame, Oxon, sent two boxes of *Maréchal Niel* Rose blooms extremely fine. Messrs. Barr & Son, King Street, Covent Garden, had a large group of *Daffodils* and hardy flowers. Mr. H. B. May, Edmonton, showed a collection of Ferns in pots, comprising some of the most distinct and useful for market purposes. Messrs. H. Lane & Son, Berkhamstead, had a group of *Rhododendrons* in pots, dwarf, compact, bushy specimens, well flowered, and the group was brightened by the plants of *Azalea mollis* associated with the others.

Messrs. B. S. Williams & Son, Upper Holloway, staged a handsome group of *Amaryllises*, including specimens of some of their best varieties; plants of the graceful *Rhododendron Williamsi*, with neat compact globular heads of small blush nearly white flowers. *Spiraea astilboides*, with long plume-like spikes of white flowers was also well represented, and a capital collection of *Clivias* bearing large trusses of their deep orange flowers completed an important group. Messrs. Paul & Son, Cheshunt, exhibited a small collection of hardy plants, amongst which was a box of *Doronicum plantagineum excelsum*, the flowers large and brilliant. *Fritillarias* also were noteworthy.

From the Royal Gardens, Kew, came a group of plants and flowers, as usual including many of great interest. *Streptocarpus Dunni*, a Natal plant, with peculiar dull reddish flowers, arising in dense clusters from the one enormous whitish deeply ribbed leaf was prominent; but perhaps the most remarkable was the flower of *Aristolochia Goldiana*, which is one of the largest in the genus, and was illustrated in this Journal on page 456, vol. xxxviii., second series, June 10th, 1880. Flowers of the peculiar and celebrated *Amherstia nobilis* were included in the collection, the long dense blue spikes of *Echium callithyrsus*, the red bud-like flowers of *Crinodendron Hookerianum* from Chili, the slender graceful blue-flowered *Tropeolum azureum*, several *Rhododendrons*, and a basket of *Primulas* completed the collection. T. H. Burroughes, Esq., 16, Lower Berkeley Street, W., showed a group of *Anemones*, comprising some handsome varieties of *A. hortensis*, *A. nemorosa*, *A. Pulsatilla*, and *A. ranunculoides* (vote of thanks).

Mrs. Grinling, Harrow Weald House, Stanmore, showed a plant of *Ochna multiflora*, bearing a large number of its curious bright red calyxes and small globular green and black fruits (vote of thanks). Mr. Wythes, Syon House Gardens, showed a group of *Pernettya mucronata*, flowering stems of *Ruscus androgynus*, the beautiful blue *Papilionaceous Clitoria ternatea*, and the white *Solanaceous Anthocercis viscosa*.

Messrs. J. Veitch & Sons, Chelsea, exhibited large plants of the white-flowered elegant shrub *Chionanthus virginica*, the rosy salmon double *Azalea roseiflora* (Rollissoni), and a *Paeony* named *Reine Elizabeth*, with very large deep rose-coloured flowers.

Medals were awarded as follows:—Silver-gilt Banksian to Messrs. Ryder & Son, silver Banksian to Messrs. B. S. Williams & Son, bronze Banksian to Messrs. J. Veitch & Sons and to Messrs. H. Lane & Sons.

ORCHID COMMITTEE.—Present: T. B. Haywood, Esq., in the chair, and Messrs. A. H. Smee, Sidney Courtauld, H. M. Pollett, H. Ballantine, James O'Brien, Lewis Castle, F. Moore, Henry Williams, E. Hill, J. Domy, A. Sander, D. B. Crawshaw, J. Douglas, and Dr. M. T. Masters.

The Orchids were not quite so numerous as at some of the previous meetings, but there were some notable plants, and certificates with awards of merit were adjudged in several cases. Mr. A. H. Smee, in exhibiting a yellow variety of *Odontoglossum triumphans*, read the following interesting note:—"Some years ago, when experimenting with flowers and plants placed in a weak solution of silicate of soda, I noticed that the plants and flowers were affected by the solution according to the colour. The colour, I found, disappeared in the following order—blue, lilac, red, brown, whilst yellow was the most persistent. Green behaved according to whether blue or yellow predominated in its composition. It has occurred to me whether the white varieties of flowers are not found amongst plants in a similar order. We have an example of the blanching of the old flowers of *Franciscas*. Then, again, in the poor varieties of the *Vanda cœrulea* the petals are almost

white, with very pale blue veining. In *Cattleyas* the colour of the petals and lips disappears, leaving the yellow throat and pale pink tint, which so often spoils a white *Cattleya* from a florist's point of view. Therefore as yellow is so persistent we cannot expect a *Cattleya citrina* to appear amongst our white varieties. The white *O. crispum* is due to disappearance of the brown blotches, leaving only the yellow markings on the column, and in the case of the yellow *O. triumphans*, which is a poor form of the ordinary type, the brown blotches are either absent or are in process of disappearance. The only pure white forms of Orchids are *Cœlogyne cristata alba* and *Dendrobium Kingianum album*."

Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, exhibited *Dendrobium sulcatum* with a short raceme of golden flowers; an excellent plant of *Oncidium phymatocilum*, having three large panicles of flowers, the long, narrow, twisted, pale yellow brown spotted sepals and petals and white lip brown at the base, having distinct appearance (cultural commendation), and an inflorescence of *Phalenopsis grandiflora* having thirteen uncommonly large flowers. R. J. Measures, Esq., Camberwell, sent a plant of *Cypripedium Apollo*, an interesting hybrid, but it was passed by the Committee. Malcome E. Cooke, Esq., Kingston Hill (gardener, Mr. Cullimore), had a small group of *Odontoglossums* and *Masdevallias*. Mr. Smee showed a plant of *Dendrobium thyrsiflorum* with three long racemes, and Messrs. J. Veitch & Sons sent plants of *Cattleya columnata* from C. Acklandiae and C. intermedia, the sepals and petals spotted with deep purple on a light ground, and with a crimson lip, also *Cypripedium Priapus* from C. philippinense and C. villosum.

CERTIFICATED PLANTS.

Odontoglossum triumphans aureum (A. H. Smee, Esq., The Grange, Wallington; gardener, Mr. Cummins).—An excellent variety with large flowers and of a deep yellow colour, with a few lighter markings. One of the best of the yellow-flowered forms of *O. triumphans* yet exhibited, and a decided acquisition. (First-class certificate).

Cattleya Lawrenceana Vincki (Baron Schröder).—Though remarkably distinct in colouring this could not be described as rivaling the typical form in attractions. The sepals and petals are tinted with a pale delicate mauve colour, the lip being a much deeper shade of a similar colour. Specimen flowers of a good variety of C. Lawrenceana as grown at The Dell were also shown for comparison, and the distinctness of the variety Vincki was very striking. (First-class certificate).

Odontoglossum verrillarium, Le Doux's variety (G. Le Doux, Esq., East Moulsey, Surrey).—A variety notable for the large size of the flowers, the lip being broad, rounded, and white, the sepals and petals faintly tinted with rose. (Award of merit).

Odontoglossum Pescatorei variety Mrs. G. W. Palmer (G. W. Palmer, Esq., Elmhurst, Reading; gardener, Mr. B. Dockerill).—A most beautiful variety with well formed flowers, the sepals and petals broad, white, with numerous bright purple spots towards the centre of the flower. (Award of merit).

Nephrolepis exaltata plumosa (H. B. May).—A dwarf compact growing variety with short divided fronds tufted or crested at the points, thus giving a plumose and elegant appearance. (Award of merit).

Rhododendron Williamsi (Messrs. B. S. Williams & Son, Upper Holloway).—A free and graceful *Rhododendron* with narrow leaves and abundant compact globular trusses of delicate blush nearly white flowers. The floriferous character of the plant will render it a favourite with all who have not grown it, and the moderate size of the flower heads render it lighter and more elegant in appearance than the majority of *Rhododendrons*. (Award of merit).

Primrose Red Gauntlet (G. F. Wilson, Esq., Weybridge).—An effective variety of the Scott Wilson group, the flowers very large, deep purplish blue, with a dark red centre. (Award of merit).

Primula cortusoides Distinction (Messrs. Ryder & Son).—A fine variety with large deeply fringed flowers, bright rose, lighter in the centre. (Award of merit).

Mignonette Garaway's Double White Improved (Messrs. Garaway and Son, Bristol).—Flowers large white and fragrant, in long close spikes.

PRESENTATION OF MEDALS.

At 3 P.M. the usual general meeting of the Fellows was held in the Drill Hall, Sir Trevor Lawrence, Bart., M.P., presiding. The ordinary business, such as reading the minutes of the last meeting and the election of Fellows, having been completed, the President introduced the principal object of the meeting—namely, the presentation of the Veitch Memorial medals to Mr. David Thomson, Drumlanrig Gardens, and Mr. Bruce Findlay, curator, Botanic Gardens, Manchester, for distinguished services to horticulture. After briefly reviewing the numerous claims to the honour possessed by Mr. Thomson as a practical and most successful gardener, and as the author of several useful works on horticulture, he handed the medal to that gentleman, who was received with loud applause when he rose to reply. His remarks were brief and to the point. He said how deeply he appreciated the honour that had been paid to him, and modestly urged that he could only claim to be a successful servant. Sir Trevor Lawrence then referred to the good work performed by Mr. Bruce Findlay in organising extensive shows at Manchester, and remarked that the award of the medal was only a just recognition of the ability he had displayed. Mr. Findlay was heartily cheered, and replied, also briefly, but owing to the noise in the Hall at the time his remarks could not be heard by many persons. Following this the Rev. Wolley Dodd gave a lecture on *Primulas*, in which he recounted his experience at

some length, and several Fellows joined in the discussion which followed.

[Mr. Thomson and Mr. Bruce Findlay were entertained in the evening at dinner by the Horticultural Club in the Hotel Windsor, when the chair was occupied by Dr. Robert Hogg.]

ROYAL BOTANIC SOCIETY.

APRIL 23RD.

IN its main features—the non-competing exhibits—the second Spring Show of the year in the Regent's Park Botanic Gardens on Wednesday last was a repetition of that held on the previous day in the Drill Hall at Westminster, therefore it is only necessary to say that the display was a good one as regards numbers and diversity, the whole of the corridor and a portion of the conservatory being devoted to the exhibits. The weather was changeable, but the attendance of visitors was satisfactory for a spring show, as, strangely enough, these earliest horticultural attractions rarely result in large gate receipts, either in the metropolis or the provinces.

Some of the chief exhibits apart from the trade collections may be briefly noted first. Six capital Azaleas gained Mr. H. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate, the premier award in the class, Roi d'Hollande, Charmer, and Reine de Pays Bas being exceptionally well flowered. Mr. R. Scott, gardener to Miss Foster, The Holmes, Regent's Park, was a good second. Mr. C. Turner was easily first in the nurserymen's class for six Azaleas with moderate sized but well flowered plants, Mr. H. James's third prize being of poor quality.

Mr. J. Douglas, Great Gearies Gardens, Ilford, was first for twelve Auriculas, excellent plants of good varieties. Mr. A. J. Sanders, gardener to Viscountess Chewton, Bookham Lodge, Cobham, was second. Mr. C. Turner, Slough, was first with twelve Alpine Auriculas, Messrs. Douglas and Sanders following in that order.

Messrs. Paul & Son, Cheshunt, were adjudged premier honours for nine Roses in pots, first-rate plants of Innocente Pirola, La France, William Warden, Magna Charta, and Alphonse Souper being notable. Mr. W. Rumsey was second with smaller plants. Messrs. H. Cannell and Sons, Swanley, Kent, won first honours for twelve tuberous Begonias with handsome double and single varieties of beautiful types. Mr. D. Phillips had the only nine Pelargoniums, healthy, well flowered plants, and was awarded the first prize. The same exhibitor took similar honours with twelve Cinerarias, followed by Mr. Douglas. Messrs. Paul and Son were first with a dozen excellent Amaryllises. Mr. Douglas was first with hardy Primulas, followed by Messrs. Paul & Son. Mr. T. S. Ware was first for a large collection of hardy herbaceous plants. Mignonette was excellent from Mr. W. Morte, Regent Street, Mrs. H. W. Morte, Fenchurch Street, and Mr. Phillips, Slough.

The non-competing exhibits included a grand bank of Primula cortusoides varieties from Messrs. Ryder & Son, Sale, Manchester, more tastefully arranged than on the previous day; an effective group of flowering and foliage plants from Messrs. Laing & Son, Forest Hill. Messrs. B. S. Williams & Son, Upper Holloway, had a group of Amaryllises, Spiræas, Rhododendrons, and Clivias; Messrs. Barr & Son, Covent Garden, a large collection of Daffodils; T. H. Burroughes, Esq., Ketton, showed a group of Anemones; Mr. W. Morte had a group of flowering and foliage plants. Mr. J. Douglas sent a collection of Auriculas and Primulas; Messrs. Paul & Son a group of hardy plants; Mr. T. S. Ware contributed a large group of Daffodils; Roses in pots came from Messrs. W. Rumsey & Son, Rhododendrons from Messrs. H. Lane and Son, and Maréchal Niel Rose blooms from Mr. J. Walker, Thame.

NEWCASTLE-UPON-TYNE HORTICULTURAL SOCIETY.

THE spring Show of the above Society was held on Wednesday and Thursday last in the Town Hall and Corn Exchange, Newcastle-on-Tyne. The spring Show of the above Society in the north of England is generally looked forward to most eagerly by the general public as well as the gardening world, and the past Exhibition was very satisfactory. The past season having been very mild gave great impetus to the development of the usual spring flowers, such as Hyacinths, Tulips, which were only on an equality with the exceptionally well-developed specimens of stove and greenhouse plants. The Azaleas in the latter class were very good, while the splendid plant of Rhododendron Veitchianum, exhibited by Mr. F. C. Ford, Pierremont, Darlington, along with Azaleas made that department most effective. A new feature this year in the Exhibition were the Trumpet Daffodils, which Mr. J. W. Watson, nurseryman, Fenham, exhibited in good style. The Staging Committee at Newcastle, with Mr. E. Wilson as their guide, generally endeavour to vary the arrangement every year, so as to cause a more pleasing effect in the blending of the various plants and flowers, and this year their efforts on all sides were considered most successful. The bouquets, buttonholes, and epergnes were, as usual, placed upstairs in the Town Hall on a long table occupying the centre of the Town Hall. These were excellent, which can be understood when it is stated that Messrs. Perkins of Coventry, and Mr. Armstrong, florist, Newcastle, were among the exhibitors.

Appended is the list of the Judges' awards. There are, generally speaking, three divisions; the A division open to all, the B to gentlemen's gardeners, and the C to amateurs only. In the A division, for four plants, Mr. F. C. Ford, gardener to Mrs. Pease, Pierremont Hall,

Darlington, was an easy first. The specimens were Erica Victoria Regina, 5 feet across, well and strongly flowered, and perfectly fresh; Imantophyllum miniatum superbum, sixteen trusses, very highly coloured and foliage in good condition; Tremandra verticillata, a mass of bloom. We have now only to mention Rhododendron Veitchii, which was in splendid condition, full of bloom; in fact, covered with its charming large white flowers. Mr. James Wood, gardener to T. Lange, Esq., Heathfield, Low Fell, Gateshead, was second. Mr. E. Adams, Swallow, was third. For four Azaleas Mr. F. C. Ford was also first, exhibiting Vesuvius, Roi d'Holland, Duc de Nassau, and Antonelli. All good examples of culture, and not too stiff as to tying down, but evenly furnished with foliage. Mr. John McIntyre, Darlington, was second with Apollon, a pure white, and Chas. Van Eckhaute, creamy white; Duc de Nassau and Madame Le Febvre, scarlet and crimson respectively. Mr. James Wood in this class was third. For three Orchids Mr. Ford followed up his former success, and was first with Coelogyne cristata, 4 feet across, profusely bloomed, and the flowers all lying neatly on the foliage; Dendrobium nobile, a very fine plant, the sepals darkly marked and very large; the other plant, Oncidium leucochilum, was also very fine. Mr. Wood was second with Dendrobium nobile Heathfieldianum, having nine spikes; also a Dendrobium Wardianum and nobile. These were the only exhibitors in Orchids.

Dielytras, Deutzias, Genistas, Spiræas, Cinerarias, Lily of the Valley (all in pots of six, save the Genistas, which are three), form a very strong feature in this Show, and were a marvellous display. The following were the chief prizewinners:—Mr. J. McIntyre, Mr. Jos. Puntun, Mr. Paul Blanchard, Mr. W. L. L. Thompson, Mr. George Brown. There were this year no Cyclamens. For six fine pots of Lily of the Valley Mr. W. J. Watson was first, and for six hardy Primulas, which are always well shown at Newcastle, Mr. W. L. Thompson was first with Primula nivalis, lutea plena, cortusoides amena, lutea alba, and lilacina. Table plants were capital from ten competitors. Mr. J. McIntyre was first with even examples of Cocos Weddelliana, Geonoma gracilis, Croton aigburthiensis, Dracæna angustifolia, and Aralia gracillima. The Society offered a prize for Strawberries, which only brought forth one competitor, Mr. J. McIntyre, who staged some specimens of what was apparently Kean's Seedling.

Auriculas are always a very important exhibition at Newcastle. This year for twelve Auriculas (nine varieties) Alpines excluded, Mr. R. Patterson, gardener to Mrs. Backhouse, Ashburton Hall, Sunderland, was first with Heatherbell, P. D. Horner, Frank Simonite (good), Heroine, John Simonite, Aeme (five pips)—this plant received the premier award of the Exhibition for one plant—Back Bess, George Lightbody, Headley, Campbell's green edge, and Chas. J. Perry. Mr. W. H. White, Killingworth, was second with Aeme (good), Frank Simonite, Prince of Greens, Heroine. For six Auriculas, same as above, Mr. W. Thompson was first with Trail's Beauty, George Lightbody, Chas. J. Perry, and Aeme (eight pips). Mr. Patterson followed with Competitor, General Neil, Frank Simonite, Magician, and Campbell's greenedge. For four Mr. Patterson and Mr. Thompson reversed positions with similar varieties; while for two distinct, one green edged and one grey, Mr. Patterson was again first. For one white edged Mr. Battensby was first with Frank Simonite. For twelve Alpines, not less than nine varieties, Mr. R. Patterson was again first, followed by Mr. White, Killingworth, the former showing in true Auricula style Llewellyn, Mrs. Dodwell, Reuben, Diadem, Queen Victoria, King of the Belgians, and George Lightbody, the latter unique. Mr. R. Patterson is a new Auricula exhibitor at Newcastle Show, and has done well, and it is hoped he may display the same success and energy in future exhibitions. In this class alone there were seven competitors, many of whom exhibited very good flowers. For six Polyanthus, gold laced, Mr. Stobbs was first with George the Fourth (Bucks), President, John Wright, Queen of the Tync, Prince Regent, Cheshire Favourite. Mr. Stobbs was also first for one gold laced variety.

Hyacinths, as usual, form a most important feature of the above Show, and this year as regards quality and quantity formed no exception to the rule, Mr. W. J. Watson being first again with very fine flowers, well developed, good colour, and foliage in excellent condition. The best flowers among blues were King of Blues; white, Mont Blanc; lilac, Lord Derby; red, Von Schiller; cream, Grandeur à Merveille. There were also of various shades Ida, Macaulay; La Grandesse Czar, Peter, and Blondin. Mr. Henry Dewar, nurseryman, Newcastle, was second with creditable specimens, the best being Lord Derby, Fabiola, La Grandesse, The Sultan, Czar Peter, and a fine violet blue Souvenir de J. H. Veen. Alexander Kerr & Sons, Kelso, were third. For twelve varieties of Hyacinths, single, not less than seven varieties, Mr. J. Watson was again first, flowers similar to those mentioned, but including fine flowers of Lord Derby, General Havelock (a fine violet blue), also Von Schiller and Grandeur à Merveille. Messrs. Henry Dewar were second, and Mr. Edward Laidlaw, Sunderland, third.

Single Tulips were very fine this year, and included the usual well known varieties, Messrs. Watson and Dewar occupying the same position in their former competition. To six pots of double Tulips Mr. James Ward was first with fine open flowers of Tournesol (scarlet and yellow), Duke of York, and Imperator Rubrorum. For six pots of Polyanthus Narcissus Mr. J. McIntyre, Darlington, was first, followed by Mr. J. W. Watson, and for six pots of Trumpet Narcissus, a new feature in the Exhibition, Mr. W. J. Watson was first. Although there were no other competitors the decision was most just, and gave great satisfaction for this a new feature at Newcastle. In the corresponding class B for Hyacinths Mr. James Wood was most successful, winning the first prize for twelve and six Hyacinths, and also first for Tulips. For Azaleas Mr.

F. C. Ford was again first for *Dielytra* and *Deutzias*. Messrs. F. C. Ford and Wood respectively took first, and for *Spiræas*, *Cincarias*, *Primula sinensis*, and six pots of *Lily of the Valley* Messrs. Paul Blanchard, W. B. Forsyth, Joseph Punton, and John Morris, Felling-on-Tyne, the latter a builder, and all through the Exhibition exhibited first-class plants, the *Lilies of the Valley* in this class being especially admired. In the amateur or C class, open to cottagers only, Messrs. E. Adams, Thomas Ruskham, John Battensby, Jos. Collinson, J. Birkinshaw, Wm. Muir, J. Morris, R. C. Hope, and Thomas Battensby were the most successful exhibitors.

Cut Flowers and Table Decorations.—For twelve *Camellias* Mr. James Wood was again first, and for twelve *Rhododendron* blooms Mr. F. C. Ford was as usual first. For twelve Rose blooms of *Maréchal Niel* Mr. Jas. Wood was first, and received the special certificate of the Royal Horticultural Society. For twelve Show and Fancy Pansies Mr. Thos. Battensby was respectively first. *Epergnes*.—These, as we have said before, form a most distinguished feature of the Spring Show at Newcastle, and the smallest epergne, arranged by Mr. O. Lamb, gardener, South Hill, Chester-le-Street, was a creditable example of what judicious taste can do combined with a *recherché* variety of stove and greenhouse flowers also arranged and displayed in faultless style. As regards colour and placement, this young exhibitor on all sides was awarded that the opinion of the Judges in premier prize was most deserved. To describe the epergne as best we can. *Lygodium scandens* was used in the upper tiers of the March stand most effectively, *Anthurium Schertzerianum* and *Andeanum* amongst bright coloured flowers were most effective, *Zygopetalum Mackayi*, *Phaius grandiflora*, and *Cypripedium Lawrenceanum*, *Lilium Harrisii*, white *Camellias*, *Roses*, *Eucharis amazonica*, were all used with good effect, as well as varieties of *Amaryllis*, all worked in with due regard to colour and effect. Mr. F. E. Edmondson, Newcastle, was second with a very fine epergne. *Marguerites* were used with much effect, as well as many other choice flowers, and the whole was evenly draped with *Asparagus plumosus*.

Bridal bouquets were tasteful. Messrs. Perkins & Son, Coventry, were first with a marvellous bouquet, including many choice flowers. Amongst Orchids were *Odontoglossum grande*, *Ceologyne cristata*, *Pan-cratiun*, *Eucharis*, and some marvellous *Roses* of *Niphetos*, *Stephanotis*, *Lily of the Valley*, and white *Lapageria*. Amongst foliage *Caladium argyrites* was deftly worked in. Miss Emily Armstrong, Neville Street, Newcastle, was second with flowers similar to those mentioned, except the favourite *Tabernaemontana cymosa flore-pleno* was used. *Cymbidium aloifolium* was also very useful. Mrs. John Jennings was third. In this class there were five competitors. For a hand bouquet Miss Emily Armstrong was most deservedly first. Many choice flowers were used, including *Cattleya Mossiae*, *Sophranitis grandiflora*, employed so as to have a most telling effect, and *Roses*, all being dispersed over with *Adiantum gracillimum*. Messrs. Perkins & Sons were second with a very fine bouquet.

For a lady's spray Messrs. Perkins were again first, employing *Odontoglossum grande* and *Alexandra*, *Oncidium*, other choice flowers, *Caladium argyrites*, and *Asparagus* were also entwined gracefully amongst the flowers. For a buttonhole bouquet there were numerous competitors; Miss Emily Handyside, Newcastle, was first, including *Odontoglossum Alexandra*, *Bouvardia* (scarlet), *Lily of the Valley*, and *Adiantum gracillimum*, this was first amongst twenty competitors. In the corresponding class for an epergne Mr. J. Battensby was first, and for a hand bouquet Miss Emily Armstrong was first with similar to her first prize in the other class, and with the addition of *Catherine Mermet* *Roses*, and *Dendrobium nobile*. Mrs. John Jennings was second; *Odontoglossum Alexandra* and a fine specimen flower of *Cattleya Mossiae aurea*, the sepals of a charming primrose colour, were much admired.

Several local nurserymen contributed stove and greenhouse plants, which added much to the attractiveness of the Exhibition, including Messrs. J. W. Tait, W. R. Armstrong, John Jennings, Newcastle; Wm. Fell & Co., Hexham; Kent & Brydon, Darlington; John Morris, Park Road, Felling; W. Smout, Trinity Street, Leeds, exhibited a fine stand of dried seaweeds. The receipts for the two days were a few pounds short of last year. The Committee were, as usual, indefatigable in their exertions to render the Show a great success, and aided by their accomplished Secretary, Mr. Jas. J. Gillespie, the visitors were well looked after, and the indispensable attention to exhibitors was not forgotten.

THE BIRMINGHAM SPRING SHOW.

APRIL 16TH AND 17TH.

In the tenth annual Exhibition, regarded as the best the Society has held, Orchids were a great feature, and in an extra group Mr. Charles Winn of Selly Oak exhibited, was a plant of the beautiful *Cypripedium Lathamianum*, raised by Mr. Latham of the Birmingham Botanical Gardens, the result of a cross between *C. villosum* and *C. Spicerianum*. In the class for twelve Orchids the first prize was won by the Right Hon. Joseph Chamberlain, M.P., amongst which were notable examples of *Dendrobiums Wardianum*, *Freemani*, and *crassinode Barberianum*, *Oncidium Marshallianum*, *Cattleya Mendelli*, a well flowered plant of the bright *Ada aurantiaca*, and *Cattleya Lawrenceana*. Mr. C. Winn was second with good specimens of *Masdevallia Harryana*, and *Cypripediums Schroederae*, *Warnerianum*, and *villosum*. Third, Mr. G. H. Kenrick, who staged *Odontoglossum citrosum*, *Dendrobiums Wardianum* and

thyrsoflorum, and *Cymbidium Lowianum* with others. In the class for six Orchids Mr. C. Winn was second with capital examples, including *Cypripediums villosum* and *venustum*, and a good plant of a grand *Cattleya Trianae formosa*, the labellum large and very rich in colour, with a bright yellow throat. The Right Hon. J. Chamberlain, M.P., securing the first prize with some good plants, which included handsome specimens of *Odontoglossum Andersonianum*, *Cattleyas Schroederi* and *Lawrenciana*, and *Dendrobium Wardianum*.

Sir Thomas Martineau's first prize six stove and greenhouse plants were well done specimens, all flowering plants. *Azaleas* were very good, not monster specimens, but clean, well-grown, and flowered. *Hyacinths* were well represented, considering that so many collections grown in the district were over. Mr. Charles Showell took the first prize for well-grown specimens, which included some new varieties. Other successful exhibitors were Mr. G. Newell, gardener to Mr. G. H. Kenrick; Mr. J. Beesley, gardener to Mr. N. Thwaite; and Mr. W. H. Dyer, gardener to Mrs. Marigold.

Tulips were numerous and good. Mr. Cooper, gardener to the Right Hon. Joseph Chamberlain, M.P., was first with stove and greenhouse flowers, and was throughout a very successful exhibitor. A few *Auriculas* were staged, but were not up to the mark generally. The best were Duke of Wellington, Frank Simonite, General Niel, John Simonite, Robert Trail, and Alpinis, John Leech, Mrs. Ball, Sailor Prince, Rival, Mrs. Thompson, and Mrs. Dodwell. Mr. Cooper, The Gardens, High-bury, obtained the first prize for six superb *Cyclamens*. Mr. Brasiere had some grand specimen plants of *Hydrangea Thomas Hogg*. Plants of *Azalea mollis* in variety were excellent. *Deutzias*, *Spiræas*, and *Dielytras* are always shown well here.

Several non-competing exhibits were staged, and *Narcissi* in a cut state were conspicuous. Mr. Thomas Ware, Tottenham, set up an extensive collection. Messrs. Dickson & Co. Limited, Chester, also staged a collection of about fifty varieties. Messrs. Cutbush & Son, Highgate, Nurseries, London, sent some very fine *Cyclamens*, *Boronia heterophylla*, a gem amongst hardwooded plants, cut *Narcissi* and *Crown Imperials*, and other plants. Messrs. Richard Smith & Co., nurserymen, Worcester, contributed a large group of forced *Rhododendrons*, *Azalea mollis*, berried *Aucubas*, *Clematises*, and Japanese Maples. Messrs. Pope and Sons, nurserymen, exhibited some new *Clematises*, the double *Pelargonium Le Buant*, a group of *Primula marginata*, and other plants, and a stand of very fine fancy Pansies, as well as artistic floral arrangements. Messrs. Thomson, nurserymen, set up an exquisitely arranged group of plants, in which a circle of *Primula obconica* was conspicuous, and also a massive and handsome memorial anchor of flowers of great beauty. Messrs. Pope & Son took the first prize for bouquets with a splendid example of artistic work. Messrs. Hewitt & Co., nurserymen, had a small but charming group, in which were two patches of the old Hoop Petticoat *Narcissus* and fine *Lilium Harrisii*, also a group of hardy spring flowers. Mr. Shuttleworth had a large assortment of rustic garden adornments, lightly and artistically made.

FRUIT FORCING.

VINES.—*Early Forced.*—In the earliest house red spider may be expected. Paint the return hot-water pipes with sulphur mixed with milk so as to form a thin paste. Give the border a thorough watering, mulching afterwards. This refers to the inside border. Apply the water early in the day, so that surplus moisture may pass off before closing time. Early Grapes do not always colour well, the defect arising from overcropping or continued hard forcing. It is only avoided by a constant supply of dry warm air and a low night temperature. Where Grapes are fully ripe a reduction in temperature is advisable, yet moderate moisture should be maintained for the benefit of the foliage. The moisture will not do the Grapes any harm provided the air is changed by free ventilation. Afford a temperature of 60°.

Succession Houses.—Attend to stopping and tying the shoots. Where the space is restricted stop the shoots two joints beyond the fruit, and as foliage is necessary leave the laterals on the shoots both above and below the bunch, or at least those from the two lowest eyes, and those level with and above the bunch. Pinch those at the first joint, especially those from the basal leaves, also those above unless there is space for extending the laterals, when they may be allowed to make two or three leaves, but no more growth should be encouraged than can have exposure to light and air. After the space is fairly furnished keep the growths closely pinched to one joint as made. Where there is more space stopping will not take place until growth has extended four or more joints beyond the fruit. The great evil is overcrowding, which deprives the foliage of the light and air, and restricting the growth is intended to avoid that.

Tying the Shoots.—Securing the shoots into the places where they are to remain during the summer is an operation which commands much attention. It is a common practice to begin to tie down the shoots as soon as they are long enough to bend. This is not advisable

except as a precaution against injury from frost, as the shoots at this stage are so tender that the slightest twist the wrong way breaks them. It is a better plan to defer tying down until the shoots are less sappy, which may be when the fruit is formed, but a better plan still is to so dispose the rod that the shoots, instead of being brought down to a nearly horizontal position, will have a good incline upward, yet sufficiently outward or oblique to admit light to the basal leaves of the shoots.

Muscats in Flower.—Afford a free circulation of air rather dry, and a temperature of 80° to 85° or 90° by day, falling to 70° or 65° at night, raising the points of the bunches to the light, and liberate the pollen at midday by gently rapping the footstalks of the bunches. If there is a deficiency of pollen take it from those that afford it plentifully, such as Black Hamburgs, and apply it to the shy-setting varieties with a camel-hair brush.

Thinning.—Where there is a quantity of Grapes to be thinned commence as soon as they are out of flower with the free-setting varieties, such as Black Hamburgs; and some, like Gros Colman, Gros Guillaume, and Trebbiano may be thinned whilst they are flowering. Follow it up early and late and on dull days. Surplus bunches may be removed, as overcropping proves fatal to colour and finish.

Young Vines.—Those planted last year are breaking naturally, and may be assisted with gentle fire heat in cold weather. The canes will have been fully depressed, so as to cause them to break regularly down to the basal buds, when they can be tied in position. Dishud, leaving the best shoots about 18 inches apart on both sides of the canes. Crop very lightly, one or two bunches being the maximum. Any extra Vines planted to fruit early and afterwards to be cut out may carry a bunch on each, six or eight bunches, or even more, according to the vigour of the Vines.

Planting Vines.—This is the best time for planting young canes. We prefer the borders partly within and partly outside, planting the Vines inside the house. For very early forcing the borders are preferably inside, otherwise we do not advocate confining the roots in this way. The border should be concreted at the bottom unless it has a substratum of gravel or other porous substance; rubble 1 foot thick must be placed on the concrete, and proper drains and outlets provided. Thirty inches depth of soil is ample. Turf 3 inches thick taken off loam friable rather than tenacious, broken up roughly and mixed with a tenth of old mortar rubbish, charcoal, and some crushed bones, form a suitable compost; but well-drained and fertile garden soil will grow serviceable Grapes. The Vines, it is assumed, were cut back in early winter and have been kept in a cool house, the eyes now having grown 2 or 3 inches long. Turn them out of the pots, remove every particle of soil, carefully preserving the fibres. Spread the roots out straight and flat, the soil of the border having been brought to the required level, covering the roots to the depth of about 4 inches, working the soil well amongst them with the hand, and giving a good supply of water at a temperature of 90°, mulching with a little short litter. If the canes have not been shortened do not cut them now, but remove the buds from the upper portion down to where fresh growth is desired to issue, and cut away the disbudded part when the Vines have made some leaves, as there is then no danger of bleeding. Six feet width of border will be sufficient to commence with. Sprinkle the Vines and house twice a day, but avoid sharp forcing. Temperatures of 55° at night, 65° by day artificially, and 70° to 75° with sun are suitable. If the weather be bright and the panes of glass large, shade lightly from 10 A.M. to 2 P.M., when the house should be closed, damping all available surfaces. If the temperature run up to 85° or more it will be an advantage. When the Vines have started into growth give every encouragement, increasing the temperature to 60° to 65° at night, 70° to 75° by day, and 80° to 85° from sun heat.

CUCUMBERS.—Despite the cold winds these have made good progress lately, and require attention in tying out the growth, stopping one or two joints beyond the fruit, removing bad leaves and exhausted growths, so as to maintain a succession of healthy fruitful shoots. Water plants in houses abundantly, and with weak liquid manure about twice a week, syringing the foliage and walls daily about 3.30 P.M., when the house can be closed. Preserve a night temperature of 70°, 70° to 75° by day artificially, 80° to 85° from sun heat, ventilating from 75°, being careful to avoid cold and drying currents of air, and close sufficiently early to run up to 90° or more with plenty of moisture in the house. Sprinkle available surfaces in the evening occasionally with liquid manure, or fresh horse manure on the surface of the bed will answer the twofold purpose of evolving ammonia to the benefit of the foliage, and supply nutriment to the soil as well as encouraging surface roots.

Pits and Frames.—Plants in those will hardly need shading as yet, but they must not be allowed to flag. Use tepid water through a rose watering pot at about 3 P.M., closing the lights at the same time, but as the nights are as yet cold be careful that the foliage becomes dry before night. Close early, employing a good thick night covering. Maintain a good bottom by linings, renewing them as necessary. Pot or sow ridge varieties if not already done, keeping these and other young plants near the glass.

MELONS.—The fruits of the earliest plants are growing large, they must have the supports lowered. Frequently stop the laterals, or thin them where they are crowded. Supply water or liquid manure liberally to plants on which the fruit is growing fast, but avoid excess of liquid manure, which may injure the roots, and the fruit in consequence will not finish satisfactorily. Plants coming into flower should not have

very copious supplies of water, only affording sufficient to prevent flagging, and a drier condition of the atmosphere is essential to a good set, especially so in the case of very vigorous plants. Attend regularly to the setting of the blossoms. Stop the shoots, however, one joint beyond the blossom when impregnated, but after the fruit is set remove all superfluous growths. Avoid giving stimulants to plants until the fruit is swelling, when liquid manure may be afforded liberally, especially to plants carrying heavy crops, until they are well advanced towards ripening. Maintain a night temperature of 70°, 70° to 75° by day, and 80° or 90° with sun heat, when the plants may be syringed lightly, except such as are in flower. Watch for canker at the collar, and rub it out with fresh slaked lime when it makes its appearance.

THE FLOWER GARDEN.

Shrubby Calceolarias.—There have been very few losses among these this season, and all are now growing strongly. Left much longer in the cutting beds the greater portion will be spoilt, and the sooner, therefore, they are temporarily bedded out the better. If there are only a few dozen plants these may be transferred to shallow boxes of rich soil in preference to potting off singly into 5-inch pots, as there are often many failures in the case of the latter after they are finally hedged out. For larger quantities a rough frame or turf pit ought to be prepared, placing in this, on a hard bottom, 4 inches or rather more of old hotbed material, making this quite firm, and placing on the top of it 2 inches of loamy soil. In this the Calceolarias may be planted about 6 inches apart each way, and if duly protected with either lights or mats and otherwise attended to, extra strong plants will be available for bedding out, and which will move with a good ball of soil about the roots. Top the plants once only, and that a few days prior to moving them from the cutting beds.

Lobelias.—Evidently the seed was well matured last season, for it never germinated more quickly and surely. The seedlings being much crowded ought first to be pricked out 2 inches apart each way in shallow boxes of good fine soil and kept in gentle heat. They must be topped early, and when neat little plants are formed these may well be transferred to beds of fairly rich soil in frames or pits, disposing them not less than 4 inches apart each way. If there is a little bottom heat so much the better, and in any case they ought to be kept somewhat close and warm till all are growing strongly. Being kept from flowering, strong stocky plants altogether superior to anything in pots or crowded in boxes will be ready by the end of May. Divisions and cutting-raised plants may be similarly treated.

Perennial or Herbaceous Lobelias are very fine for either flower beds or borders, well repaying for any little trouble needed in their cultivation. Plants from seed sown in gentle heat would be too late to flower this season, but they might prove most serviceable next spring. Seedlings now well advanced in growth to be pricked out either in boxes or pans of good soil or potted off singly, and if kept in gentle heat till well established, then duly hardened and planted out, the greater portion will flower late in the summer. Old plants wintered under glass ought ere this to have pushed up numerous strong suckers, and each of the latter that may be separated, with a few roots attached, from the old stem will make a good flowering plant this season. Either place these divisions in boxes or pot off singly into 3-inch pots. Plant out early. Seedlings varying in character considerably should first be planted in mixed borders, the divisions obtained from named or selected varieties being the best for beds.

Tuberous Begonias.—Those intended for bedding out ought never to be placed in pots, this remark applying both in the case of seedlings and old bulbs. Prick out the former first rather thickly in pans of light fine soil, and from these transfer to larger boxes or pans, arranging them about 4 inches apart each way. They grow more strongly in and move more readily out of boxes of fairly rich compost, and if kept in gentle heat till they are nearly large enough to put out, being then properly hardened off, an early and continuous display of bloom may reasonably be anticipated. Old bulbs to be also started in boxes or frames of rich but not heavy compost, from which all can eventually be transplanted with good balls of soil and roots, the latter soon taking possession of the soil in the beds. Little or no heat is needed for these old bulbs, but care must be taken not to sour the fresh soil by over-watering at the outset.

Zonal Pelargoniums.—It is a great mistake to cut down autumn struck plants for the purpose of obtaining cuttings, as they seldom make good progress afterwards. Top them once or twice if dwarf bushy plants are needed, but if all are put out in a slanting direction and perhaps pegged down it is not advisable to stop them, spreading plants filling up best. It is the old plants stored thickly in pots and boxes that should be freely cut up, every shoot from these striking readily, and can be grown to a good size by the end of May. Spring struck plants of the variegated forms are in some respects superior to those raised in the autumn, and cuttings of these may be taken up to the end of April, or even later. A rather dry position, such as an old flue or a staging over the hot-water pipes in a vinery, is what suits Pelargonium cuttings, water being given rather sparingly at the outset. All experience the least check when planted out from small pots, but if the latter are not sufficiently plentiful let the more delicate variegated varieties have the benefit of them.

Annuals.—The present is a good time to sow Asters, Stocks, Zinnias, and Helichrysums in gentle heat, but Marigolds, which germinate quickly and grow rapidly, ought not to be sown for another fortnight.

THE BEE-KEEPER.

NOTES ON BEES.

THE WEATHER.

FROM April the 6th to the 11th the weather was raw and frosty, 2° being registered every night until the last-named date the thermometer sank to 19½° Fahr. Slight showers fell, but not so much as in any way to retard outdoor labour; but the foliage of trees and bushes have a sickly hue, and it is to be feared fruit blossoms may suffer. Bees are still advancing, but have been for a week kept well within doors, and although honey gathering ceased there has been no loss of bees. Everywhere I go bees are in a forward state, the result of favourable weather, and being put up for winter with ample provisions. To all appearance swarming will be general in May.

FEEDING.

This must not be neglected, as the numerous young bees now creeping out of the cells daily demand large supplies of food, more than is generally gathered until May is out, and even then must not be neglected unless the weather is fine. Hives allowed to go back from now till honey comes in plenty will remain unprofitable throughout the year.

DRONE COMB.

The health and laying condition of the queen regulate worker combs, but it is not always safe to trust entirely to this. Queens have laid eggs long already, and when Nature demands a rest the bees fill up all gaps with drone combs. To avoid this the bee-keeper should fill all spaces with comb or comb foundation that may be considered unnecessary to be filled with drone comb.

QUEEN REARING.

This may be begun earlier than in former years, and as youthful, fertile, and healthy queens are the foundation of profitable bee-keeping, care and attention should be paid to have these in sufficient numbers to meet all requirements, and raised in the most natural way possible. Never raise queens for stock from a hive that has been queenless for a length of time, as the bees are liable in such cases to bring forward imperfect queens. Always select a good and strong hive. The queen may be simply removed, but it is better that a swarm should issue or be taken artificially, thereby removing the older and leaving mostly young bees behind, which are Nature's queen rearers.

SIZE OF THE HIVES.

Where common-sense bee-keepers have wintered the bees in full-sized hives, except when two swarms are united, it is unnecessary to put a single swarm into a hive of similar dimensions at the first, especially where super comb is wanted, two divisions of the Lancashire divisioned hive being sufficient, but it should be enlarged to its full size on the introduction of a young queen. Then it is in the best of condition for late and abundant honey gathering.

EXTRACTING.

Where extracted honey is wanted, full sized supers are the best to employ, as the combs being shallow the bees fill and seal them more quickly than they do deeper frames, and honey should on no account be extracted until the combs are sealed.

JARRING HONEY.

Although the screw cap has a neater appearance than the tie-over jars, they are not so well adapted for keeping preserves unless hermetically sealed. A simple and effective way of doing this is to cut pieces of foundation or plain and perfect sheets of wax into proper sizes, laying one upon a board previously steeped in water and heated a little. Press it firmly to the top of the jar and it adheres, making a complete air-tight seal. Tie-over jars should be treated in the same manner before the parchment is tied. A gentle-

man who had some of our wild Thyme honey a few years ago, kept it in an air-tight jar for some years, and every time it was opened he informed me the dining room was highly perfumed from its fragrance. The new fangled methods of treating honey has done much to lessen the demand.

SHEETING SUPERS.

Filling sections and supers with full-sized sheets of foundation too has had a similar effect, and has tended more to the reduction in price than increase of production has done. With all the points as a standard for judging honey put forth by our savants, the most important one of rejecting comb showing the midrib of foundation has been omitted!—A LANARKSHIRE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Fungus (*Fungi*).—What you send appears to be a malformed example of the Morel, *Morchella esculenta*, and if so it is, as its specific name indicates, edible. We are, however, not positive on the identity of the imperfect specimen. You should have stated the conditions under which it was found growing.

Warts on Vine Leaves (*R. B.*).—The granulated appearance of the leaves sent is the result of sap extravasation through the epidermis. The warts are injurious as impeding respiration. The affection may be caused by too much moisture in the atmosphere with heat. Mr. William Thomson, in his practical essay on the Vine, says he can produce or prevent the affection by a close, warm, and too moist atmosphere in the former case, and a free circulation of air with moderate moisture as a preventive.

Dandelions in a Lawn (*H. E.*).—It is useless cutting out the plants and leaving a good portion of the roots in the ground, as fresh growths will be sure to push from them. Two or three drops of sulphuric acid (oil of vitriol), kept in a stone blacking bottle, and drawn out in notches cut in the end of a stick, and placed quite in the hearts of the plants will burn out the roots, but the acid must not touch boots, clothes, or hands, or it will burn them too. We have seen thousands of Dandelions destroyed in the manner described. The work should not be entrusted to women or boys.

Pruning Marechal Niel Rose (*J. R. N.*).—You may not only cut back what may be termed the lateral growths, or shoots which have produced flowers, to good buds nearly close to the main stem, but you may cut back the stem to any desired extent in case the upper part is not so strong and healthy as you may wish. By syringing freely twice a day in dry weather, and maintaining a genial atmosphere, fresh growths will soon start, and the plants being healthy and kept clean the shoots will become strong enough and firm enough for producing flowers in abundance next year. As a rule, the closer the pruning the better the resulting growth.

Stephanotis Flower not Lasting (*J. T. W., Deal*).—When the plant is grown in a hot moist house and the flowers are cut and taken direct to a cold or dry room it is not surprising that they fade quickly, and this is often the cause of Stephanotis lasting so short a time. If the flowers are cut in the morning with the sun shining upon them they are not so likely to last well as if cut in the evening, or at least when the sun is off the house. They might be cut and placed for a time in a slightly cooler place before being used, and you cannot have anything better as packing material than clean fresh moss. This may be covered with tissue paper if there is danger of soiling the flowers. If the plant is healthy as you say and flowers freely do not remove it, for you would find it difficult to secure a substitute as useful.

Vines from Cuttings (*A. C.*).—If the cuttings you inserted in the spring of 1888 have made no growth we should think they are dead.

Cuttings inserted too late in the spring, and then not deep enough, often fail. Well ripened portions of young wood should be chosen for cuttings, and inserted immediately the leaves fall. They may be 8 or 9 inches long, removing all the buds but two at the top, and only this portion should be above ground, the longer portion in it in a slanting position, with sandy soil pressed firmly round them. When a trench is made for the cuttings it is a good plan to place a quantity of sand in it and press the cuttings down in it. You may try some now, and if only one or two buds are above ground some of the cuttings may perhaps grow. The wood must be firm, and if secured with a heel of last year's wood they will not be less likely to emit roots.

Fungus on Vine Roots and Leaves (T. E. H.).—The roots sent are infested with a fungus. This is the result mainly of too rich soil. The root appears to have been taken from a mass of wet humus. Firmer, stronger soil is needed by Vines. Perhaps the best thing you can do now is to give the border a heavy dressing of newly slaked lime, spreading it on a quarter of an inch thick, and lightly pointing it in. Then when the surface is dry, not otherwise, tread it firmly. The leaves sent are much deficient in texture and unable to purify the crude sap and secrete nutrient matter, hence the exudations which have been taken possession of by another fungus. Employ less moisture both in the border and atmosphere, discontinue the use of liquid manure, and maintain a buoyant atmosphere by judicious ventilation. Possibly the Vines may be too heavily cropped, and it is certain they are in a very unsatisfactory condition.

Destroying Woodlice (G. H.).—The most wholesale mode of riddance is to place some boiled Potato round the inside of the frame or pit on the surface, and cover with a little hay loosely. Do this as a bait for a couple of nights, and in the morning of the second night have some boiling water in a watering pot, and pour it through the spout on the hay around the sides of the pit or frame. This will not do any harm to the plants provided it is not used upon them, or even to their roots, unless used in excessive quantity. It may be necessary to repeat it in the course of a week, which the presence or otherwise of the pests will determine. Some baits formed by placing a boiled Potato wrapped loosely in a little hay in a small flower pot laying on its side near the haunts of the woodlice in the evening, and in the morning shaking the vermin into a bucket of scalding water from the hay in which they will be secreted after or still feeding on the Potato. This persisted in will eradicate them. A toad introduced will devour great numbers, and is an aid in the destruction of woodlice too seldom called into requisition.

Culture of Justicia calytricha (T. S. C.).—You are right, it is one of the most beautiful plants that can be grown for the decoration of the conservatory or intermediate structures from December until the end of March. The beautiful light feathery plumes of this plant last a long time, and after the first flowers fade a second crop is produced. This plant must be grown on from cuttings annually, for old plants seldom grow with such vigour or produce such large plumes of flowers as young plants. Old plants from their slow stunted growth often become a prey to scale, which is not the case where plants are raised from cuttings every year, provided they are not grown too warm. Old plants that have flowered should be pushed into growth in a warm house, for the sooner cuttings can be obtained the better. When strong cuttings have been produced they should be inserted singly in small pots, and if kept close in the propagating frame every one will root. They should be grown warm until they are established in 8-inch pots, and from this stage an intermediate temperature should be given them. After the middle of July they should be grown in cold frames.

Culture of Nertera depressa (J. R. W.).—The following is the note you require:—"I have grown it for the last few years as follows:—The plants were kept in a greenhouse until the berries died away, when some plants were started for the succeeding year. This would be in autumn about the end of August. Pans about a foot in diameter were well drained and filled up with soil, the soil being put in firmly and slightly raised above the level of the pots, small pieces of the Nertera being pricked in like seedling plants or cuttings. The pans were then set on a shady shelf in a stove, keeping the plants moist at the root, and syringing over the tops. After the plants had filled the pans they were removed to a coolinery, only supplying sufficient water to keep the plants moist and in a fresh condition. The soil I used was similar to what young Cinerarias will thrive in—a mixture of loam, leaf mould, decayed manure, and sand. In spring to start the plants into growth they were put on a shelf near the glass of a Peach house, and watered overhead sometimes three or four times a day, according to the weather. On this shelf the pans remained until the berries began to colour, when they were removed to the greenhouse. With this treatment as fine specimens were produced as could be desired, and they were particularly noticed by visitors."

Bed for Carnations (J. B. N.).—As the position on the south side of a wall will, perhaps, be hot and dry in the summer, you must provide a depth of at least 2 feet of good soil for the plants. It does not follow that the present soil need be excavated to that depth, as it may probably suffice to clear out the stones and rubbish down to the heavy loam, then break this up well and enrich it with manure, also spreading on a good thickness of manure before filling up with fresh compost. This should be 18 inches in depth. There is no better soil than turfy loam, inclining to heavy rather than light, that has been in a heap for six months or more, and perfectly free from wireworms that are not infrequently present in loam recently dug from a pasture. To five barrowfuls of loam add one of decayed manure—that from a cow

stable preferably—dry enough to be broken into small particles for mixing, half a barrowful of wood ashes and the same of vegetable refuse, with an 8-inch potful of soot and the same quantity of bonemeal. Turn the whole a few times, or till the ingredients are uniformly incorporated. Provided the compost is neither very wet nor very dry when placed in the bed, and is pressed down rather firmly, it should grow Carnations well. It may be desirable to cover the surface of the bed between the plants 2 inches thick with very short manure, or if you prefer something that may be deemed more presentable, with cocoa-nut fibre refuse. The sooner Carnations are planted the better, and they should be strong, and now established in pots for flowering well this year. They can then be planted without any material disturbance of the roots, and great care must be taken that the balls of soil from the pots are not by any means dry, neither excessively wet, when inserted.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*H. S. Easty*).—*Ornithogalum nutans*. (*B. B. K.*).—*Aucuba japonica*, var. *longifolia*. The seeds appear to be sufficiently ripe for sowing. (*J. J.*).—*Begonia peltifolia*. (*B. C.*).—A variety of *Anemone hortensia*. (*G. R. S.*).—1, *Asplenium Ruta-muraria*; 2, *Asplenium viride*. (*E. C.*).—The plant of which you send a drawing is probably *Tillandsia setacea*.

SHEEP.

Now that the lambing is ended once more even among the latest flocks special attention may usefully be drawn to points of practice which are always important, and which go far to ensure successful results both with lambing and general flock management. Sheep are hardy animals—able to endure much exposure, to bear much neglect; but there is a limit even to the powers of endurance in a sheep, and it has been proved beyond question that losses to a very serious extent have been caused solely by mismanagement.

Let every flockmaster, and every shepherd too, ask himself, How has the lambing gone this season? If there were cases of abortion, was the reason known or was it doubtful? An occasional case of abortion may occur in any flock, but it is when abortion becomes rampant and dozens of lambs are lost that it becomes evident the management is at fault. One safeguard against abortion is to mark every doubtful or faulty animal during the lambing, or immediately after it is over, for drafting from the flock when the lambs are weaned. Mark also all full mouth four-shear ewes, and do not be tempted to keep them for that other lamb, as has so often been done, for the result is to say the least decidedly speculative. Rather resolve to draft all ewes at the proper age, and to keep up the number by annual selections of the best ewe lambs. Were this a fixed rule in all established flocks there would be much less risk of loss, and results generally would be altogether better.

When Professor Axe went into Lincolnshire to inquire into the cause of the outbreak of abortion before and during the lambing season of 1883, he found foot-rot rampant in the flocks of that county, and in his report he says, "That animals should give up the fruits of conception when tortured by the pain and suffering which extensive and unprotected ulcers of the feet entails, is no matter for surprise," and he adds, "especially when, as in the present case, they are worn down by exposure, fatigue, and the pernicious influence of a cold ungenerous diet." That exposure and low diet was mentioned to mark the evils of folding pregnant ewes on Turnips. In this instance, of 7800 ewes fed exclusively on Turnips, 22 per cent. aborted, and of 13,800 others receiving more substantial food, only 6 per cent. were so affected. Of the 51,475 ewes comprised in this inquiry, 6234, or about 12 per cent., aborted, and 1494 died. Foot-rot may be kept down by incessant watchfulness and care, so that the general health of the sheep is not seriously affected, and in so mild a form it will not cause abortion. But at the date of the inquiry the practice among the Lincoln flocks was of a very rough-and-ready description. The report says that the soil of the folds was worked up into a veritable puddle, or, what is worse, an impassable slough, rendering the recumbent posture all but impossible, and the poor beasts, with their heavy burden of young, stood in mud over their hocks and knees for many successive days, and some are stated to have got down in the mud and were obliged to be killed in the last stage of exhaustion.

Most lamentable was the mismanagement, the misery, and sufferings of the poor animals, and the heavy losses it caused. Really, one would suppose flockmasters who could suffer such a state of things to exist must not only be blind to their own interests, but also sadly deficient in practical knowledge, to say nothing of common prudence and the dictates of humanity. In his "Recommendations" Professor Axe placed much stress upon the importance of shelter against cold winds and driving rains. He was right, and we repeat here that every field or meadow used for sheep should have shelter in the guise of open commodious

edges, and we know no better structures for this purpose than the modern ones, with sides and roofs of corrugated iron sheets.

The sowing of root crops has begun again in view of the provision of food for another winter. If the roots can be consumed upon the land it is altogether best, but do let us try so to manage that there shall be no compulsory folding in unfavourable weather, and no use of roots for pregnant ewes. With draft ewes, store hoggets, and ewes with the lambs we may surely manage to get through our folding and root consumption. The old plan of following hoggets with pregnant ewes to consume Turnip shells left by the hoggets must be abandoned. Much better is it to cut up the "shells" with hoes as the hoggets are withdrawn and plough them in, for they are excellent manure. Instead of sowing so many roots that the ewes must be fed with them, rather let us resolve to reduce the root crops within reasonable limits, to have more Cabbages and Kale, and to make as much silage as possible, for in it we certainly have sound wholesome food good for ewes or any other animals.

WORK ON THE HOME FARM.

The two-year-old colts intended for use are gradually being broken to work. This enables us to keep mares with foals from being worked too early. Colts require gentle handling and much patience. Leading is taught early. They are placed singly in a team of steady horses with equally steady men out upon the land first of all, and are fairly settled to work before they even leave the farm for road work. Many colts prove troublesome when first shod, and by way of precaution we usually have this done when a colt is tired from a long day's work. Very seldom indeed is it that we have any trouble with a mare in foaling. Our favourite arrangement for brood mares is to let each of them have a commodious lodge with a sliding door on small wheels or runners, so that when the lodge is open the door cannot blow-to or become partly closed, and so become an obstruction, and perhaps cause injury to mare or foal. When closed the lodge is practically an admirable loose box, with just a manger, rack, water trough, roof ventilator, and window for the admission of light only, either well protected with iron bars or else high up out of reach. The lodge opens into a small yard enclosed by posts, rails, and stout boards resting upon brick footings. This sort of enclosure answers better than brick walls or corrugated iron, both so liable to injury from horses. In front of the yard is a paddock, so that by this arrangement we have the lodge, yard, and paddock always available, and the mare may foal in either place according to the state of the weather. When a mare is exhausted by foaling it has a gallon of gruel with a pint or two of ale; bran mash and corn are given for about a week after foaling, and then the ordinary diet is resumed.

A certain number of new hurdles are required each year, and we like to have our supply now, so as to use them for sheep folding of roots now and green crops later on. As corn and other crops spring up sheep will break out if there is a weak or badly set hurdle in a fold, and a few acres of corn are soon spoilt. We allow the shepherd to use no old hurdles where it is possible for sheep to do harm, and take care to see that his folds are well set.

Winter Beans, on heavy land especially, have lost plant since the severe weather of the first week in March, in some parts to such an extent that Oats are being drilled to fill up the vacant places. This is all the more provoking as the Beans were exceptionally promising, but after a mild moist winter there is always considerable risk of loss from a sudden change to colder weather. We shall revert to this flaw in the Bean crop next week, as we have heard doubts expressed as to the cause.

REMARKS.

13th.—Bright and cold.
 14th.—Bright day; slight showers in evening and night.
 15th.—Cloudy early; bright, mild morning; a little cloud in the afternoon; wet night.
 16th.—Cloudy and mild, with slight showers in morning.
 17th.—Overcast all day; damp evening.
 18th.—Drizzle all the morning and in the evening; overcast afternoon.
 19th.—Dull and damp early; cloudy morning; fair afternoon, but no bright sunshine.
 The average range of temperature has been less than usual, the maximum on two days being below 50°. There was a sharp grass frost on the 13th. Barometer rather low, but with easterly winds.—G. J. SYMONS.

WHATEVER the ultimate results may be no one can venture to question the endeavours of the Directors of the Society to make its influence felt in the horticultural world. Its policy is distinctly progressive, and the most active workers on the Council do not spare themselves in seeking to provide the Fellows with the best that can be given in return for their support. Whether it is actually the "best" that could be produced is perhaps a debateable question, but the intention is not the less apparent. Not only has there been a considerable increase of Fellows of late, but not a few of the horticulturists now enrolled are evidently ready and willing to render service to the Society in any way they can. The Committees are earnest in the discharge of their duties, although now and then incidents are said to arise that are not the most conducive to harmonious co-operation. It may be that humble workers who do their best to aid are over-sensitive, and there is always the possibility of activity being misinterpreted for mere interference. Be that as it may, it is to be hoped that pushing and peddling in high positions or low will never interfere with the smooth working of the component parts of which this, in common with all societies, are constituted.

The increased support that has been given to the Royal Horticultural Society by the press and the public has been based on the assumption that, in the discharge of its functions, action would be taken on broad lines, and that something more than an ever recurring series of small shows, attended by a miserably small number of visitors, would be provided. Periodical meetings, as such, and held for distinctly technical purposes, are desirable, useful, and even essential, but to magnify these meetings into "shows" in the hope of attracting the *élite* of London society cannot be regarded as other than delusive. Nothing is more quickly determined by the educated portion of the community than the difference between the general competitive gatherings of the best men and best produce in furtherance of good objects and mere trade bazaars. It is no fault of business men that they avail themselves of such facilities as they find for presenting their wares to each other, and where their character will reach the ears of the outer world. They would be very remiss if they did not, but the fact remains that neither bunting nor board men can compel the public to rush to the Westminster Drill Hall to admire "shows" of that character. The "genial faddists" to slightly alter a Blackmorean phrase, convinced themselves that such would be the result of a spirited Hall policy, but the hope, as some of the quiet observers anticipated, has proved futile. The difference between a legitimate exhibition and ordinary fortnightly "shows," as estimated by the public, was apparent last week on the occasion of the National Auricula Show, when for the first time during the season the attendance was satisfactory. It was a pleasure to see such a gathering; also encouraging, for if the public will flock to see a real show of flowers in a back street, what may we not expect if a hall for horticulture becomes established in a commanding position? But mere "banks" of flowers and collections of fruit of a non-competitive character, and distinguished by the name of "shows," are not what the public expect in these days, and it is well known that visitors to these "shows" have gone away disappointed, and have not induced their friends to give their patronage to such gatherings.

Yielding to none in the intensity of our desire for the prosperity and usefulness of the Royal Horticultural Society, we have not been able to acquiesce in what may be termed the Drill Hall policy; and though some of our references to the building at one time did not meet with the unanimous applause of all our friends, we stopped very far short of Baron Schröder's comparison of the building to a "dust-bin." We thought from the first acquisition of the volunteers' rendezvous that it would cost more than it was worth, and we suspect such is the fact, and we shall be heartily glad if the requisite support is given to Baron Schröder to enable him to carry out his project.

We have not seen any statement of accounts in which the costs and revenue of the Drill Hall are clearly set forth. In the revenue account "cleaning" is connected with rent, but no allusion is made to labour, though this must be a considerable item. Is it included in the Chiswick Garden expenses, and if so, why? This question has been suggested by a gentleman of a somewhat high position in the horticultural world, and he is of opinion that Chiswick has been made to appear as costly as possible, and he thinks the "&c." attached to the extraordinary amount charged for implements, considerably more than £100 during the year, is not so clear as it should be. He asks, "What are those implements?" and the question appears to be a perfectly legitimate one.

Rightly or wrongly, the feeling is not obliterated that the Council of the Society are not in deep sympathy with Chiswick. In the report it is specially singled out for its cost, though nothing whatever is said about the cost of the Drill Hall, yet it is not beyond the bounds of probability that Chiswick has helped the Hall materially, and is accorded no credit for it. Again, attention is markedly called in the Report to the unsatisfactory attendances at the Chiswick conferences, though no correlative allusion is made to the greater paucity of the visitors to the fortnightly "shows" at Westminster; and it would be interesting to know what the payments have been to these meetings by the visiting public. With all its cost it is a question if the "return" to Chiswick is not greater in proportion than that to the Drill Hall in relation to the outlay, including the medals so generously "recommended" there, though perhaps they are not all granted; and beyond all doubt a large number of the Fellows, and especially those who have become so during the past two years, consider Chiswick the backbone of the Royal Horticultural Society.

They would like to see the London expenses reduced rather than the gardens should suffer, and they will not think that the great cost of the new *Journal* of the Society will be justified if the maintenance of the gardens is likely to be imperilled. The production of the series is a well-meant effort, but there is room for a compression in bulk and improvement in quality; and a change in both those respects would reduce the cost and enhance the acceptability of the issues. The last issue contains a great deal of worthless matter on Chrysanthemums, while several of the "papers," though good, are no better than nor different from articles which appear in the weekly gardening press; only two or three, of which Mr. Burbidge's may be taken as a type, are distinct from ordinary garden literature. It is the same in the vegetable department, and with the exception of Mr. Veitch's address, and perhaps Mr. Laxton's contribution on Peas, the remainder might have been either dispensed with or materially condensed—not because, as we have said, the matter is not good, but because the Society is not rich enough to indulge in the luxury of circulating matter of a kind which ninety out of a hundred of its supporters can and do find when they want it in weekly periodicals.

The *Journal* of the Society as now issued is not sufficiently distinct in character, nor by any means such a well finished production from a scientific, literary, and editorial point of view as it ought to be, and unless it improves in all those respects it cannot be long considered as worth the money it costs. A copy has been sent to us in which several errors are pointed out, including the

thrice mentioned name of Monsieur Henry de Vilmorin, in each case differently and in all inaccurately; and that *Hortus Kewiensis* was allowed to "pass" is at least surprising, while the name of Mr. Donald Munro given as Mr. *Douglas* Munro is more surprising still.

It would be tedious to point out all the imperfections. The reference to their existence is needed, and that may perhaps suffice. We give all credit for good intentions, but good judgment and good workmanship are essentials in the successful conduct of a Royal Society, or there is danger of too much being done in one direction and too little in another, for the true interests of the Society, which we desire to see prosperous and strong.

FORM

THERE is a sense in which form is employed which will not be touched on in the present article. I refer to the "form" which florists and plant growers strive for respectively in their flowers and specimens. Possibly the tone of what follows might be thought to condemn the work of both, and it may therefore be as well to say here that the point of view from which the subject is regarded precludes either praise or condemnation. The extraordinary strides which gardening is taking towards the purely decorative in conjunction with the artistic tastes of present everyday life brings the question of form increasingly to the front. We all have to study it, though no doubt there are those who do so without giving it the position which it is its right to occupy. Colour alone for a long period occupied the mind of the gardener, and he massed colours in blocks, or in contrasting lines in the garden beds and borders, and under the same principle, though with necessary modifications, employed flowers in greenhouses, and in vases and bouquets. But colour has been slowly and surely losing its supremacy, and in few gardens I should imagine occupies the absorbing position it did. We shall never expel bright and cheerful colours from our gardens and homes, but they must come to occupy the position of handmaids to form.

It is indisputable that to-day we have a greater range of plants to select from than at any other period in the history of gardening. Hardy plants themselves form a host, which the worst equipped garden can freely employ: and where wealth abounds taste may in addition call in the help of tender plants almost without limit in their variety. If we first of all take into consideration the decorative plants of the garden we find them roughly divided into two sections, the one like the purple Heather spread over broad moors and upland ranges, distinctly carpeting plants; the other, like Daffodils, rising in clumps from the daisied turf, the representative of form in plants. There is space enough and to spare for both sections. For broad masses of single Snowdrops and Winter Aconites in earliest spring; for Primroses, Polyanthus, Squills; for dwarf Bellflowers, Pansies, Sedums, Saxifrages; for Lobelias, Calceolarias, Pelargoniums, Paris Daisies, and Dahlias; for these and many more. But besides these there are noble plants which must be seen standing clear of all others, or springing from an undergrowth of spreading living green. Such we find in the numerous bulbous plants which flower in summer and autumn; the commoner Lilies, Hyacinthus candicans, Gladiolus, Montbretias, Irises; also Chrysanthemums, tall Carnations, Hollyhocks, Japanese Anemones, Spiræa Aruncus, Sunflowers, tall Ceanothus, Lupines, Tritomas, Golden Rods, and many others. All these have a beauty of form apart altogether from the colour of their flowers, and to crush them into borders in graduated order from front to back is not the happiest method of treating them. The most glorious of all hardy flowering plants is the Hollyhock when allowed to carry five or six main spikes with branching side shoots, but if crushed up and tied together to allow other three or four tall growing plants room to perform their restricted duty the whole of its beauty is destroyed. Then how distinct in habit is the common Tiger Lily when allowed to grow in its own way, and a clear space left to see it all round. Among Irises, too, there is an infinite variety, from the grass-like ruthenica to the broad-leaved pallida. To hide the beauty of form in any way is to lose one of their greatest charms. What charming plants are the Montbretias! Even without flowers they would be worth showing off, but with the flowers how beautiful their "form." Take the vast group of Gladiolus. How graceful the tall byzantinus! And almost the whole of Lemoine's earlier hybrids are most distinct in form. Then take the common Solomon's Seal set in a prominent position with nothing but dwarf plants round it, and what can excel for beauty of form its bending wreath of flowers in early summer or of beaded fruits in autumn? We have no need to call in the aid of tender exotics when these

and so many other plants with leaf and flower are ready at hand if properly arranged to yield a new form of beauty.

To hothouse plants very much the same remarks apply. We can pinch and train the Fuchsia, and make beautiful specimens; but a freely grown young specimen allowed its natural bent will not yield for beauty of form. Then, what so graceful as well-grown pyramidal Celosias? And Carnations, especially the strong-growing kinds, such as Comtesse de Paris and the Malmaisons grown naturally and without pinching, are most beautiful in form and adapted for decorative work. Or if we select Crotons, what a wonderful amount of beauty of form in this one family. Tall single-stemmed plants of the Wiesmanni or Warreni class and branched examples of the angustifolius group are not to be surpassed alike for richness of colouring and for beauty of form. But in the case of these and of all other plants which have "form" every portion of each individual should be clearly shown. It should never be forgotten that one perfect plant surpasses any number that are imperfect, and that it is wasteful to crush up good plants for the sake of getting just so many into a group or decorative arrangement. This is one of the clearest principles.

Touching now on "form" as applied to cut flowers, exactly the same remark applies here. If a gardener selects flowers which have colour alone to recommend them he will always, no matter how tasteful his arranging may be, fail in making a striking effect. A few plumes of Pampas Grass, with leaves from the same plants or with a few common Rushes intermixed, will make a most graceful centrepiece. A large vase will be nobly decorated with six or seven Arum spathes and a few Arum leaves. Small glasses will be amply furnished with a few sprays of Lily of the Valley, and a leaf or two of the same. Or what more charming than any of the Narcissus? three or four flowers if set in a wealth of their own leaves making a most beautiful picture; and these are so amenable to forcing that a very great variety can be grown all through the winter and spring. Every one of these examples are noteworthy, because they place "form" far in advance of colour. This is one great reason why Orchids are so vastly ahead of all other flowers for cut decorative purposes. A few Orchids judiciously used have an effect in rooms which no other flowers can compete with. But a great deal can be done with the less attractively formed flowers. A round globular Dahlia or Chrysanthemum can be made to either spoil the effect of a large room or to enhance the effect of the other flowers. Supposing we take a tall vase filled with Pampas Grasses in the way already noted, now select three, five, or more Dahlias or Chrysanthemums (no matter how large the blooms), cutting in either case long stems with foliage, and set these round the outer rim of the vase, letting them stand quite clear, and drooping if they will, and if properly managed we secure a massive arrangement, and quite as beautiful in form as it was previous to the addition of these lumpy flowers.

It may be noted here that vases should receive the finishing touches after they have been set in their places. Sometimes a very slight change in the position of the flowers makes a vast difference on the effect of the whole. When very large masses of flowers are wanted there is almost sure to be a tendency of what is termed heaviness. A good plan is to put in all heavy flowers first, then lighten the arrangement by adding those which have beauty of form, adding any graceful or beautiful foliage at the same time. Here again I have seen the addition of a few flowers, insignificant looking in themselves, be the making of one of these big groups of cut flowers. But, to reiterate what has been already said, "form" is the great thing to study, perhaps more in cut flowers than in any other part of the gardener's work.—B.

NOTES ON FRUIT TREES—APPLES.

(Continued from page 336.)

SHELTER.

WHILST it is necessary to have an open exposure so that the trees may enjoy the full benefit of the morning and evening sun, as well as an inclination of the ground to admit of the sun's rays acting with greater effect, and be the more sheltered from northerly winds, it is rare that the situation is sufficiently sheltered naturally as to not require artificial shelter; but there are many slopes crowned by a wood or copse, and not infrequently these extend round to the north-east and on the opposite point to the north-west, and down the slope to the full east and west quarters respectively in a sort of amphitheatre-like shelter, leaving the points from east to west open to the sun, while the soil being good, as it generally is from the washing down of the richer parts of the higher ground, we have an ideal fruit ground already made. These already formed shelters are infinitely superior to any that can be formed by planting trees for shelter simultaneously with the fruit trees, as the latter

will derive little benefit from the screen trees until they have arrived at or passed the meridian of their profitable period. Nor is this all, for where no natural shelter exists it is a question whether forming artificial shelter will not so detract from the results as to render the affair unprofitable. This is a matter for serious consideration. It is one thing to have a slope of ten, twenty, or more acres with the shelter above indicated, for which there is no rent to pay, and having shelter to provide on ground that is rented equally with that occupied with fruit trees; indeed it is a moot question whether ground not already sheltered should not be rejected, or if sheltered at all, it ought to yield a profitable return for the ground on which rent has to be paid. The landlord might, of course, see that by planting the ground undesired by the fruit grower with forest trees, the fruit growing portion would be rendered more valuable, and bring a higher rental, such as would compensate him for the loss that must accrue on outlay in planting and loss of rent until the plantation came into profit, but unless the land was unsuitable for arable or grazing purposes it is problematical, if he would fall in with such a plan for seeking profit by letting land for fruit growing. Clearly any expense incurred in sheltering would have to be borne by the person for whose benefit it was provided, and to recoup that it must be profitable.

The progress made by vegetation on southern exposures requires protection so as to moderate the effects of cold winds. The points where protection is required are on the north, north-east, and north-west sides, as from these the winds are the coldest, and the north and north-east worst of all, therefore the shelter should approach nearest on those sides, for what is lost in light will be compensated in warmth, and the north-west, though it may be less important, should not be much further removed. On the east and west sides the shelter should be at such distance as not to deprive the site of the morning and evening sun. On the north and north-east the screen should not be nearer than 20 yards, as the sheltering trees to be of use must be larger and stronger than the fruit trees, and the shelter must be brought round similarly on the north-west. On the east side the shelter should be fully double the distance off, as on the north, north-east, and north-west sides, and it is preferable to have the shelter on the east and west in copse or clump order, and widening out to the south-east and south-west respectively, so as to leave the fruit garden or orchard quite open to the south-east, south, and south-west. In planting in clumps it is necessary to have double lines, so that the further off shall be opposite the inner intervals or openings. These will break the force of winds effectually, and letting in more light are decidedly preferable to an unbroken closer screen. In situations much exposed to the south-west it may be desirable to offer protection in the shape of outpost clumps, so as to break the force of wind before it reach the fruit trees; but they must be a considerable distance (not less than 200 yards), or they may interfere with the free access of light, which it is imperative must be afforded unobstructed between east and west. In very exposed locations the outpost system of shelter has great advantage, as with clumps of trees at 200 to 300 yards distance, an outer one at the latter and an inner one at the first, and so that they come alternate and to some extent overlapping, the force of wind is so broken that it falls very much weaker on the inner screen and makes a considerable difference in the temperature. In many, if not most, localities where suitable sites offer for fruit gardens and orchards there is generally a large amount of plantation, natural or other copse, particularly in undulating lands, along with hedgerow timber, which independently of woods that collectively so break and modify the force of winds as to render artificial shelter unnecessary, or it may be necessary to fell some of the existing trees so as to let in more of the forenoon and afternoon sun. This, however, can only be determined by ocular proof on the spot, and requires to be done with consummate judgment and knowledge of the locality.

Tall and quick growing trees should be chosen. None excels in these aspects the Larch, Corsican Pine and Scotch Fir, with the Austrian Pine for the outer and inner lines of the belt, as the Austrian Pine is very dense in growth and does not become so bare at the bottom after a few years as the other. These answer admirably on the north, north-east and north-west, and will thrive at elevations and on ground where quick growing deciduous trees could not. Poplars and Limes are much employed for shelter of this kind, to which there is no objection if the site be in a level country or where there is plenty of moisture with a good depth of soil, but they are not suitable for sheltering on high ground where the soil may be too poor from elevation, although the site to be sheltered may possess a good depth of rich soil through the washing down of the finer and richer parts from the higher ground. The belt should not be less than nine rows deep, the centre one Corsican Pine alternate with Larch, next Larch entirely, then Scotch Fir, every other plant Larch, another entire row of Larch, and an outside one of Austrian Pine alternating with Larch, repeating the

lines on the other side of the line of Corsican Pine. In the lines of Scotch Fir introduce Elm and Sycamore, or Beech if chalky, at every 16 feet, and at similar distance in the lines of Austrian Pine Mountain Ash may be planted, but Holly is preferable on the inner line. This belt would be profitable from the thinnings after a few years, and being planted 4 feet apart the trees would get up quickly, so that by the time the orchard or fruit garden was in full profit it would be materially augmented by the timber, indeed, it is questionable which of the two would upon the capital afford the best results. On low and damp soil Poplars would be most suitable, the Black Italian perhaps best, and for evergreen Norway Spruce might answer if not too much exposed, otherwise it is about one of the worst sheltering trees. For soils of medium texture Limes do very well, but they are useless in heavy clay soils, though they thrive well enough in moist and light, and they may be trained and cut so as to form a close screen from the ground upwards. It is certain that if we need screens of the deciduous character and have to pay rent or own the ground on which they stand, that it would be more rational to plant sheltering belts of the stronger freer growing kinds of Apples or Pears (and Damsons or hardier kinds of Plums for dwarf culture), for it is patent that if the soil is good enough for a Poplar, a Sycamore, or a Lime, which have little value as timber, it will grow equally free examples in fruit trees. Therefore if shelter is provided in such cases it will only need to be of a temporary nature, and the trees should be planted closely so as to grow quickly, for which there is nothing better than Poplars and Willows. Where but a low screen is wanted, as in the case of trees under dwarf culture, nothing surpasses the common Elder, and it will stand sea breezes, evidently relishing the salty air. To enable the screening trees to advance quickly, the ground should be well trenched and liberally manured, keeping it free of weeds so as to let them have full possession of the soil.—G. ABBEY.

(To be continued.)

VARIATION IN PLANTS.

(Continued from page 335.)

NATURAL ADAPTATIONS FAVOURING CROSS-FERTILISATION.

WHAT is commonly understood by the term cross-fertilisation or hybridisation is the transference of the pollen of one plant to the flower of another, and though in garden nomenclature a distinction is made between the two terms, no such distinction can occur in regard to wild plants. The fertilisation of one species by another we term hybridisation; and crossing, cross-breeding, or cross-fertilisation is usually restricted to the same process between varieties of one species. It is more convenient to employ cross-fertilisation in its broadest signification, and there are so many different grades of fertilisation, that it is not desirable to attempt a division of the subject by the use of terms so nearly synonymous.

For example, self-fertilisation pure and simple takes place when a flower is fertilised by pollen from its own anthers; if pollen from another flower on the same stem or plant is employed, we have the first form of cross-fertilisation, and the results may be quite different from those in the first named case.

The next grade is when the flower of a plant is fertilised with pollen from another plant growing in the same soil and situation, and of the same variety or species. The third grade is the fertilisation of a flower with pollen from the same species or variety, but furnished by a plant growing some distance away and under different conditions. Within the limit of one variety we thus have three degrees of cross-fertilisation, and it has been proved repeatedly that the benefit in greater fertility, better seeds, or stronger seedlings, usually increases with the divergence of one parent from the other. Thus there turns are least in the self-fertilised flower. An advantage is gained in the case of fertilisation by pollen from another flower on the same plant; this is increased when the pollen is from another plant, and still more when the plant is grown elsewhere, provided in every case they be equally healthy.

Following the grades already named, we have cross-fertilisation of one variety by another in the same species, then between two species in one genus, and lastly between two species of different genera. These six degrees represent the whole range of the combinations that can be distinguished, though there are other minor differences that have an effect though they may not always be immediately appreciable. For instance, the plants raised from a self-fertilised seed-pod might be regarded as more nearly related than any others, but there would be a slight difference between them and those from other seed pods on the same or different plants, and so on.

It is beyond all question that with many plants cross-fertilisation is a distinct advantage, and the fact that some plants are habitually self-fertilised in a wild state does not in any way dis-

prove this assertion. Nor does the occasional occurrence on plants that are normally adapted for cross-fertilisation, of flowers that specially and solely self-fertilised interfere with it in the slightest; it is only an additional method, perhaps serving some purpose which we cannot perceive. In some of the *Violas* these cleistogamous flowers are found, and it is strange that they are invariably without the brightly coloured corollas that distinguish the ordinary flowers, and they are often unobserved until the seed pods are swelling.

This most extraordinary disappearance of the floral attraction furnished by coloured corollas upon the same plant, where in other flowers they are still being displayed, brings us to a consideration of the most general adaptation to favour cross fertilisation—floral colour. A few years ago if the question had been put to a young amateur or professional horticulturist, "Why have so many flowers brightly coloured corollas?" the answer in nine cases out of ten would probably have been, "For our benefit and pleasure." But this rather selfish and narrow view is only partially true. We do undoubtedly derive much pleasure from those brought into our gardens and our houses, or those wildlings which we see in our country rambles, but it can scarcely be claimed that the millions "born to blush unseen" in tropical forests and unexplored lands afford us any pleasure. Our benefit, great though it be, is a secondary one; the primary purpose has been indisputably proved to be far more intimately connected with the plant itself.

The modern view, supported by the best authorities and by common observation, is that these richly coloured, strangely varied corollas, flaunting on the air, are simply attractions to insect visitors which unconsciously assist in cross-fertilisation by conveying the pollen to other flowers, thus contributing to a more certain production of fertile seeds, and in many cases to an increasing diversity of floral form and colouring. The odours of flowers, pleasant or otherwise, and the nectar, are simply means to the same end—namely, they serve to attract bees with other insects and gain an indirect advantage themselves. It has always seemed very pleasant to imagine that all the fragrant flowers existed alone for our delectation, but rather difficult to account for the fetid flowers. When, however, we understand that there are insects whose tastes evidently differ materially from ours, and which probably derive as much satisfaction from a well developed *Stapelia* or some of the powerful *Arums* as we do from a *Rose*, it is very much better than having to regard such flowers as wasted because we are incapable of enjoying them.

In the forms of flowers countless devices and adaptations are seen, obviously calculated to attract insects, to guide them, or in some way to make them the means of securing cross-fertilisation. This is usually more evident in the case of flowers with monopetalous and irregular corollas than in those with the petals distinct, but there are some exceptions to the rule. Still, if we look amongst the members of that large division of flowering plants, the *Monopetalæ*, which includes some of the most ornamental of our garden plants, we shall find abundant examples of floral forms especially adapted for insect fertilisation. Take, for instance, the *Salvias*, the *Antirrhinums*, or almost any of their numerous relatives, and the structure of the flowers at once suggests adaptation for some particular purpose, and a little observation will soon teach what that purpose is. Whenever flowers possess a remarkable form, a want of correspondence in the parts, an irregularity in any degree, it is worthy of special attention, for in most instances some curious adaptation will be discovered, and some particular insects are the favoured guests.

Often in the families comprising the plants with "two-lipped" corollas as those just mentioned, there are lines and markings which seem to serve as guides to insect visitors, tending in the direction of the stamens or the pistil. It is very strange that even the disposition of the colouring should seem to be in accordance with a method, and to be directed to the accomplishment of a specific object. There are, indeed, "more wonders in heaven and earth than are dreamt of in our philosophy," and the more closely the vegetable kingdom is studied the more we become impressed with this idea. No better restorative to a healthy reason could be advised for the thoughtless, and those who treat in a frivolous manner with things far beyond their comprehension, than a course of study in the plant world.—LEWIS CASTLE.

(To be continued.)

TOMATO DISEASE.

THE article on the above which appeared on page 325 by "W. S.," recalls vividly to my mind our battles with *Cladisporium fulvum* during the past three years. The year 1887 was, as all interested in growing fruits will remember, one of very hot sun-

shine. For weeks not a drop of rain fell, and but little dew, even the trees in the open being attacked by red spider. In the Channel Islands *Cladisporium fulvum* made its first appearance during the latter part of May, and from that time onward spread rapidly until I doubt if there was a single Tomato plant unaffected by this most terrible disease by the end of June. Whether in forcing or cool houses, all suffered alike, the latter coming off second best. Having had some eight years' experience at that time in growing Tomatoes for market, I was acquainted with a few remedies and antidotes for the then known diseases, but in common with most others, the fungus which followed the advent of the yellow spots threw all my efforts and experience of mildew quite out of the running. At that time no name had been found for this new form of disease, and, so far as I know, no remedy has yet been discovered that will destroy or check it effectually. As to the remedies I tried they were various. In a small house, a span 60 feet by 25 feet, heated with hot-water pipes on each side in the usual way, the plants were the least affected, and as they were carrying a heavy crop I determined at any cost to either save them or make a vigorous attempt to do so. The first notion was that the plants were suffering from insufficient moisture and nourishment, and consequently root action had been checked. To remedy this, a dressing of a celebrated plant manure was given, the whole of the loam lightly forked over, and a good soaking of clear rain water was applied. The pipes were kept pretty hot all night, and a small amount of ventilation to let out moisture arising from the heavy watering. After a few days I found the disease worse than ever and spreading to the young growths. Flowers of sulphur and air-slaked quicklime were then applied with the sulphur bellows to the under part of leaves. This, instead of checking, really appeared to assist the fungus to spread more rapidly and completely, and at this juncture I must confess I was at my wit's end. However, I decided to let them take their chance, allowing all lateral growths to push on without check, supplying a moderate amount of water to the roots, and constant ventilation. The pipes were heavily coated with sulphur and kept hot, and the glass lightly shaded with a sprinkling of limewash on the west side. The result of this treatment was a partial recovery, and eventually the plants set a late crop, which made up in some measures for the loss in midseason. In 1888, however, this remedy proved utterly useless, and all our plants were completely ruined for the early crop, and the second plants fared but little better. Last year the disease was not so fatal, so that I am in hopes we may soon see the end of it.

With regard to clubbing at the roots, my experience has been that this takes place when plants have been too tenderly nursed in the first instance while in the small pots, and then being planted out in a border, the soil of which has not been warmed by starting the fire two or three days before planting the house. The same will take place if potted in sixes, unless the soil and surroundings are previously warmed. I would advise "W. S." to procure Mr. Wm. Iggulden's last work on "The Tomato," and he will there find the matter he refers to exhaustively treated.—SARNIAN.

PHALÆNOPSES.

LARGE panicles of flowers certainly injure the plants if allowed to remain upon them until the whole fade. Where the well-being of the plants is considered the flowers should be removed before they shrivel. It is a mistake to remove the flowering portion and then allow the spike to branch and flower again. Continuous flowering over some months results in decreased vigour of the plants, but we have found no harm result from moderate sized spikes remaining on the plants until they are past their best.

COOL TREATMENT FOR PHALÆNOPSES.

Those who adopted a cool system of treatment for these plants are struggling to recruit the remains of what were once fine healthy specimens. We have seen good collections rendered worthless by changing the treatment from a warm to a cool system. If *Phalænopses* are reduced to an unhealthy condition it is difficult to restore them again to health and luxuriance. When a place is found where they do well it is unwise to remove them, for they are liable to deteriorate. During the flowering stage too

much attention cannot be paid to keeping the plants free from thrips, which attack them during the strain of flowering.

DENDROBIUM THYRSIFLORUM.

Growths will soon issue from the base in a close moist atmosphere after the plants have flowered. Be careful not to overwater

good peat the lower portion that is decomposed can be picked away and the plants repotted without the slightest decrease in their pseudo-bulbs the first season. It is necessary to break the pots, for the roots often cling firmly to them. Charcoal in fair sized lumps may be freely used amongst the peat. The plants should be fairly elevated, the peat being pressed firm and the pots

FIG. 52.—MR. BRUCE FINDLAY (see page 362).

them or the roots will perish. The supply of water must be gradually increased as the growth extends and new roots are formed. The plants may be kept in a healthy condition for a long time after they are established in fair sized pots by merely removing the surface and supplying good fibry peat. When potting is necessary all decayed matter should be carefully removed, and this may often be done without disturbing the plants to any great extent. When they have had a top-dressing of

not quite filled, so that two or three good top-dressings can be applied annually afterwards. This Orchid succeeds in a basket, but requires more attention in watering during the season of growth. A well grown plant in a basket, when in flower, is very conspicuous suspended from the roof. Where stage room is limited it may be suspended from the roof. We have frequently employed it in 6-inch pots for room decoration while in flower, and find that no harm results, provided the plants are not stood where

cold draughts will strike upon them. While in these positions they should be kept moderately dry at their roots.—ORCHID GROWER.

NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 192)

IN my last article I referred to the increased cultivation of Asparagus near London during the reign of William III., and in the eighteenth century many acres more about Battersea, Mortlake, and Deptford were occupied by this vegetable; 70 acres near Mortlake alone 'tis said. Gravesend and Reading were other localities where much was produced, the red-tipped variety, brought from Holland, superseding the smaller green-tipped, on account of its superior flavour. Scarcely any is grown at Gravesend now (I cannot speak for Reading), and of course but little in the suburbs of London. A friend is astonished that, considering the difference between our London and the metropolis of Georgian days, there should have been a demand for the vegetable calling for such extensive cultivation; but I expect that some of it was sent from London to distant places. We know for a fact that at one time the market gardens of Middlesex supplied a variety of vegetables to the midlands, and even the north of England, and Asparagus was probably amongst them.

Seakale, so familiar now as the pioneer of Asparagus, was scarcely grown at all in the reign of Anne. It had been for centuries gathered by the residents on some of our coasts, where it is found wild, and by L'Obel and Turner plants from Kent or Essex were sent to the continent, where it was soon brought under cultivation and became popular. Miller seems to have been the first English gardener who formed an idea of its capabilities as a vegetable, but the Rev. John Freeman, vicar of Sidbury between 1707 and 1713, was the first to send samples of Seakale to any metropolitan market, but the price of 2s. 6d. a root was prohibitive. A prejudice existed against this vegetable in the minds of some persons, and one somewhat similar was not in favour of Celery, which had been known as a weed, and then called Smallage. It was with the hope of improving this reputed weed, I suppose, that the early gardeners put the plants in frames to begin with, afterwards removing them when of some size to the open ground.

It is surprising that London and Wise in their "Complete Gardener" take no heed of the Potato, and Bradley in 1719 remarks slightly that he must name it, but it was of less note than most vegetables. These southerners, however, did not probably know that it was then coming largely into cultivation in Lancashire, and about 1728 a stimulus to its growth in Scotland was given by Thomas Prentice of Kilsyth, Stirlingshire, who having successfully cropped a small plot of ground with Potatoes, and being aware of the value of the vegetable, did not cook them, but distributed the first year's yield amongst the farmers and cottagers of his neighbourhood. He lived till 1792 to see the Potato a common vegetable, though some Scotch folk repudiated it because it was not mentioned in the Bible. It made way but slowly in the West of England for many years.

Bradley's many books, ranging in size from folio to octavo, and dealing chiefly with botany, gardening, and agriculture, had no doubt a considerable influence in diffusing practical information, but he was rather entitled to the credit of being a clever compiler than a man who made valuable original observations. He made some researches into the nature of circulation amongst plants, and the growth of mould in fruit, also he experimented in the production of double flowers and hybrids. He was acquainted with a large circle of gardeners whose practical knowledge he turned to good account, correcting misstatements of previous authors by their aid, and also throwing out suggestions for new methods of culture, particularly in grafting, forcing, and in transplanting saplings or trees so as to form new plantations speedily. His first publication was a book on bulbs or succulent plants, as he called them, the Tulip receiving special notice. A peculiarity of his books was that most of them had abundant illustrations drawn on copper or wood, many of the early books on horticulture being sadly deficient in this respect. His work on "Improvements in Planting and Gardening," published in 1720, contained numerous and curious designs for novelties in parterres and plots, a variety of notes on greenhouse plants; appended to this was a calendar of his own devising. To the Vine he devoted considerable space in another "Treatise on Gardening," which appeared three years later, in which he incidentally mentions that the two finest vineyards near London were Fairchild's at Hoxton, and Warner's at Rotherhithe, so that the vineyard nursery of Hammersmith had not then come into fame. In 1728 he published a small volume entirely devoted to the Vine. It was only a few years before this that the practice of forcing Vines was commenced by the Duke of Rutland at Belvoir Castle, where heat being applied from spring

to autumn a large and early yield of Grapes was obtained. At first they began by giving artificial warmth to Vines on sloped walls, but Switzer advised that this should be done under glass, and much sooner, commencing to force in December at latest.

At the beginning of last century walls were a frequent subject of experiment amongst fruit growers, and as people are apt to go from one extreme to the other, instead of the low walls common fifty or sixty years before, many had walls built of excessive height, say to 18 or 20 feet, disadvantageous for several reasons. Another alteration was that of erecting a wall on arches or piers, so that the roots of the trees might extend beneath; and also they sometimes discarded the coping, which had been general, and this enabled a tree to be trained over a wall. Moreover, it was found that the coping offered at its angle a convenient shelter for insects. In 1700 Facio de Doulier had published his work, recommending that the fruit walls should be inclined to the horizon, and his proposal was taken up by noblemen and other amateurs of the time, though gardeners mostly did not agree with his opinion. Switzer declared that sloped walls harboured damp and made the trees liable to be injured by frosts. Some German gardeners thought they gave the fruit more benefit from the sun, and they particularised the Peach and Nectarine as species that were advantaged by being placed on an incline. Another innovation of this date was the wavy or serpentine wall, one built at a less expenditure of bricks, and said to shelter the trees from the winds. It was originated in Holland, but had brief popularity. There is a sample of this style of wall at a garden near Betsom in Kent, which looks about 150 years old, and another at Ketton Hall, near Stamford. Boarded or wooden walls were also tried, the supports of stone or iron. It was usual to tar the wood very thoroughly. These, too, were put on an incline towards the north, but the practical objections to them were numerous.

Some of the private gardens formed during the reign of Anne were occasionally accessible to visitors, and helped to encourage the pursuit of horticulture. That owned by Dr. Sherard, situated at Eltham, was believed in its day to have the largest collection of exotics anywhere. Knowlton was head gardener, a man of some scientific knowledge. After Dr. Sherard's death in 1737 the establishment gradually declined. North of London the garden of Collinson, near Mill Hill, attracted many, and he in turn was a visitor to most of the nurseries then existing. Nearer to the centre of the metropolis lived Mark Catesby, on the border of Hoxton. He started for America in 1712, learnt how to etch, and drew figures of the most interesting and valuable trees he saw on that continent. Towards the end of his life he moved to Fulham, having long had an attachment to its nursery, and died there in 1749. The Duke of Argyle, contemptuously called a "tree-monger" by Walpole, had a seat near Hounslow called Whitton Place, where he planted extensive shrubberies and raised from seed a variety of exotic plants. About the middle of this century many of his plants and shrubs were removed to Kew.—J. R. S. C.

FERNS AND FERNERIES.

[Prize essay by Mr. E. Booker, Chiswick Gardeners' Mutual Improvement Association.]

CULTIVATION AND MANAGEMENT.

IN selecting the cultivation of Ferns as my subject for this essay, it is not because I have anything of importance to add to what has already been written by exceptionally able and experienced authorities on this class of plants, but they are favourites with all lovers of plants, from the richest to the poorest. They may be grown in a variety of ways—in the stove and greenhouse for decoration, or as specimens for exhibition, in Wardian cases, in the cottage window, and last, but not least, in the open garden, both in sun and shade, the shady place where many good things will not grow being especially well adapted for hardy Ferns. These plants, provided they are given their proper situations, and their several requirements are attended to, are not the most difficult plants we as gardeners have to cultivate. It will be impossible for me in one paper to treat the subject as I should wish, but I will endeavour to give a few practical remarks in what I consider to be important points in their cultivation.

Where Ferns are wanted in large quantities the best plan is to sow the spores in pans or boxes nearly three parts filled with crocks. The compost should consist of good fibrous peat, with crocks and charcoal broken up finely and some coarse silver sand all mixed thoroughly together. Fill the pans or boxes with the compost, pressing it firmly, then water and allow it to thoroughly drain. On this sow the spores, and water carefully with a fine rose. If a large quantity are sown at the same time they will be better placed under a handlight or frame, then they can be more easily attended to in the matter of shading and watering, or else they must be covered with sheets of glass. Place them in a temperature of 50° at night with an increase of temperature by day. March I consider the best month to sow, as then they will have a longer season of growth before them, although they will grow well if sown later.

In about two months or so they will begin to vegetate in the shape

of little green circular bodies on the surface, from which ultimately will spring small fronds. From this time they should be gradually brought to the light, and when large enough to handle they should be pricked off into boxes, using soil similar to that in which they were sown. Keep the soil moist, and shade from bright sunshine. After they are established they may be potted singly into thumb pots or 60's, according to their strength and the amount of roots they have. As they become established report them as they require it; never let them get pot-bound when young. Most Ferns may be kept comparatively healthy for some time by being confined in small pots, but plants so treated in their early stages are some time before they grow again freely. Another method of raising Ferns, and one requiring less time and labour where the convenience is at hand, is by standing mature plants on a strong wire trellis, under which we can have a bed of ashes; then as the spores ripen Nature will cause them to drop among the ashes, where they will germinate readily in endless numbers. If it is desirable to increase any other variety the fronds when matured must be gathered and shaken on the ashes, where the spores will readily germinate as previously mentioned.

GENERAL TREATMENT IN POTS.—About the middle of February any of the varieties of *Adiantums*, especially *Adiantum cuneatum*, should be cut down entirely, especially if at all shabby, a process I have found not to be at all detrimental, but rather beneficial. All dead or shabby fronds of the other varieties should be cut off, and as soon as they have fairly started into growth, any that require potting should be potted as carefully as possible, so as not to injure the young fronds; and any that are too large, or that you desire to increase, should be carefully cut with a sharp knife into as many pieces as circumstances may demand. Be careful not to use too large pots for small or weak growing varieties; it is far better to give them another shift, or even two, during the growing season, but for the larger plants and strong growing varieties two sizes larger pots may be used with advantage. The pots and crocks should be thoroughly clean. If new pots are used they must be previously soaked, and allowed to dry. The compost should consist of two parts good fibrous peat (broken to pieces by the hand), one part good fibrous loam, a little leaf soil and silver sand, and some powdered charcoal. This should be sifted, and the coarse used to put over the drainage, as perfect drainage is an important matter. The charcoal will keep the soil open and sweet, which is also another important point in the cultivation of Ferns. Water should be applied sparingly until the plants have commenced to root into the new soil, but when fairly established they should, when growing, never know the want of it. In fact any of the large plants which have not been repotted, especially Tree Ferns, will require water twice a day during the summer, for it is marvellous how quickly a Fern will collapse when neglected in the matter of watering. Tree Ferns are benefited by syringing the stems once or even twice a day during the summer, and occasionally overhead; but for all Ferns that are of a soft nature, such as *Adiantum farleyense*, *A. Paotii*, *A. Legrandi*, and the *Gymnogrammas*, I would not advocate syringing overhead daily; a sufficiently moist atmosphere can be obtained by sprinkling the floors and slabs two or three times daily.

SHADING.—Ferns require to be shaded from brilliant sunshine, and it is desirable to have moveable blinds, so as to use them only when necessary. They are far preferable to a permanent shading, for although Ferns like a certain amount of shade, to grow them in a densely shaded house will do them more harm than good. They will not look so well, nor their fronds keep so well when excessively shaded, for with proper light we secure a firm texture. They are of necessity subjected to a lower temperature during winter, so as to give them that one thing needful—rest, as on the little word “rest” depends our future success. To keep Ferns growing all the year round is a mistake and contrary to Nature. In speaking of rest, I do not advocate the drying off of the Ferns, or placing of them in any out-of-the-way corner, but that they should have a lower temperature, and have the water given them more sparingly, as they will not require it so often during winter.

TEMPERATURE.—Most of the Ferns I shall name in my selection are those from tropical countries requiring a stove temperature during winter of 60° at night to 65° and 70° in the day, rising as the days lengthen to 70° at night, and from 80° to 90° in the day during the summer, again declining as the days shorten.

SELECTION.—In giving a selection of Ferns I shall mention only those I have successfully grown. Of *Adiantums*, *farleyense*, *Bausei*, *concinnum latum*, *delabrilforme*, *trapeziforme*, *Williamsi*, *Lathomi*; of *Aspleniums*, *nidus*, *alatum*, *viviparum*, *Cheilanthes elegans*, *Davallia fijiensis*, *Gleichenia dichotoma*; *Gymnogramma peruviana argyrophylla*, *G. decomposita*, *G. schizophylla gloriosa*; *Nephrolepis davallioides*, *N. d. furcans*, *N. Duffi*, *Pteris tricolor*. Some of the varieties I have mentioned will grow in a greenhouse temperature, but I have found them to grow more freely in a stove temperature. *Gymnogrammas* will require to be placed at the warmest end of the house during winter, as they do not thrive in a low temperature, and they must also be carefully attended to in the matter of watering.

INSECTS that infest Ferns are aphides, scale, and thrips. I have found for aphides and thrips nothing better in the way of destruction than occasionally slightly fumigating with tobacco paper. If the Ferns have not been grown in too high a temperature, and not too densely shaded, the fronds will be better able to stand slight fumigation without injury. Scale must be destroyed by lightly sponging with warm water in which a little Fir tree oil has been mixed. I have found this safe and effectual.

THE NATURAL FERNERY.—Having given a brief outline of Fern

culture in pots I will pass on to what I will call the natural fernery, meaning, of course, a house that is (with one or two exceptions) planted with Ferns. For if we have a house with a north or north-western aspect, which could be devoted to a fernery or indoor rockery, a more natural and interesting structure it is difficult to find. The best material to be used in building a fernery of this description is what is called tufa, or Derbyshire stone. Although more expensive than burrs or cork, it is far preferable, looking more natural, and the Ferns luxuriate in it. I have found some of them to root into it so strongly as to make it a difficult task to remove them. It would be impossible for me here to give any ideas or plans of the way the rockwork should be built, but suffice it to say that it should not be made too uniform, but as irregular as possible, here projecting and there receding. The practice of employing a great number of arches and masses of overhanging rockwork should be avoided as far as possible, as it prevents the light reaching the lower parts of the fernery. Ferns so placed as to have all the light excluded from them, instead of growing luxuriantly, and becoming objects of interest, dwindle away and die, leaving bare those parts which ought to be most amply furnished with verdure, because of being below the eye of the spectator. For a fernery of this description to become effective the foliage in the lower part ought to be as luxuriant as that above, and this can only be done when we make arrangements for abundance of light. It will greatly add to the appearance of a fernery if we can have a shallow pond of water within the house, and also if in building the rockwork we let in one or two small pipes with holes pierced in them, so as to penetrate through the stone, greatly assisting to keep the stone cool and moist during the summer.

COMPOST.—The compost should be the same as previously mentioned, but it may with advantage be used a little coarser. Care should be exercised in the planting and making the plants firm, especially at the back. Commence by planting at the bottom, close to the pond, all Ferns of a water-loving nature, such as the *Polypodiums*, *Osmundas*, such as *Osmunda gracilis*, *O. cinnamomea*, and *O. Claytoniana*, *Scelopendrium vulgare*, and its beautiful crested varieties. If any other plants than Ferns are required for the sake of giving relief, there is nothing better than *Aspidistra lurida variegata*, and also that good old plant *Farfugium grande*. Both these are very partial to water, consequently should be planted close to the pond. I shall not attempt to give a long list of Ferns, but shall mention a few varieties that I have found to do well planted out. Nearly all the varieties of *Pteris*, both green and variegated, will do well. Of the green forms *Pteris serrulata*, *P. serrulata cristata*, *P. hastata*, and *P. umbrosa*; while of the coloured varieties are *Pteris argyrea*, a good variety for this purpose; *P. cretica albo-lineata*, *cristata*, and *cristata Mayi*, and *P. tricolor*. The *Davallias* are also exceedingly useful; the best for this purpose are *Davallia bullata*, *D. canariensis*, *D. Tyermani*, *D. hemiptera*, very dwarf and handsome. These should be elevated a little above the level of the pockets, as they will then turn over the sides, and will root into the tufa more easily and readily. In fact, all Ferns having surface rhizomes should be kept above or on the surface, the rhizomes should never be buried. *Nephrolepis exaltata* will be found suitable for planting close to the wall, where it will soon cover the wall and have a pleasing effect. *Nephrolepis davallioides* is another good variety, if we can give it sufficient space so as to show off its long graceful fronds. It certainly should have a place found for it, as I have seen this variety so planted with its fronds nearly 5 feet in length, and hanging gracefully. I might here state that I consider when Ferns are planted out their true and proper characteristics are better produced than when grown in pots. Amongst the *Adiantums* that may be used are *cuneatum*, *decorum*, *formosum*, and *Capillus-Veneris*; the last named is very useful for planting out, as the spores will grow readily on the tufa if kept moist, looking very pretty and effective.

Unless the house is a large one I would not advise the planting of Tree Ferns, for unless there is room for them to develop their handsome fronds they soon get spoiled. A few pieces of lichen may, if desirable, be placed here and there on the tufa, with the object of improving the appearance.

When all are planted, water carefully with a fine rose, so as to prevent the soil being washed out of the pockets. When fairly established they must have a liberal supply, and it will be necessary to damp the floors and syringe the walls at least twice a day during hot, bright weather. The Ferns I have selected being of a somewhat harder nature than those recommended for pots, will not be injured by being occasionally syringed, as the tufa must be kept moist, so as to make it become green, for the sooner it does become green the more natural will it look.

The temperature should be kept nearer to a greenhouse standard than that of a stove. In winter a temperature of 45° at night to 50° or 55° in the day will suffice, gradually rising as the days lengthen and the light increases to 60° or 65° at night, and from 75° to 80° in the day during the summer. No harm will be done if the temperature rises even 10° higher than I have stated, if caused by the sun, and if the temperature should rise to this degree, attend well to the damping of the floors. If such a house is glazed with Hartley's patent glass so much the better, as little or no shading will then be required. If shading must of necessity be used, in this case also have removeable blinds if possible. I would not advocate the use of coloured glass, as I have found Ferns do not seem to do well when placed under it.

FERNs FOR DECORATION AND CUTTING.—If Ferns are wanted for house decoration during the winter months the best plan is early in the summer to break up or divide any large plants that are at disposal

of the varieties required, or any of the seedlings that can be spared, and grow them on in heated frames, as after they are established the heat may be dispensed with. Give them plenty of light, and admit air night and day on all favourable occasions. Ferns so grown will last much longer when cut, and the plants will stand the dry atmosphere of rooms and the effects of gas much better, giving pleasure and credit to all concerned.

BLOCKS OF CORK, BARK, AND WOOD.—Ferns planted on cork, bark, or pieces of wood are both useful and interesting for hanging in the stove, fernery, or greenhouse. Some of the *Davallias* may be used for this purpose, and likewise *Stenochlena scandens*, but I do not think anything can surpass the *Platyceriums* for placing on blocks, as they display their peculiar fronds to much greater advantage on blocks than in pots. *Platycerium alcinorne* is the most free-growing variety, while *P. Willincki* and *P. grande* are, perhaps, the most beautiful and interesting. I do not advocate the planting of Ferns on blocks in moss alone, but prefer to use some rough peat; on this place the Ferns, keeping them secure by carefully passing some copper wire behind the sterile fronds. The Ferns will soon root into the peat and grow much better than they would in moss alone. They must be soaked in water when they require it, as it is impossible to water them properly with a can. My objection to the use of moss is that with the continual dipping the moss decays, and likewise the roots of the Ferns.

HANGING BASKETS.—These make beautiful ornaments, and many Ferns do well in them and show their beauty. They should be suspended, or their long, drooping, and graceful fronds are not seen to advantage. The baskets must be lined with moss or sphagnum to prevent the soil from washing out. The compost should be the same as previously mentioned. If possible when planting use those Ferns that are rather root-bound or with plenty of roots, and if planted firmly they will soon commence to grow, and at once become effective. We have numerous varieties of Ferns suitable for this purpose that will grow either in stove or greenhouse. I shall in this case also select those I have found to do well:—*Platycerium alcinorne* (greenhouse), *Adiantum ciliatum* (g), *A. cuneatum grandiceps* (g), *A. assimile* (g), *A. Capillus-Veneris* (g), *Davallia bullata* (g), *D. hemiptera* (g), *Pteris scaberula*, impatient of heat (g), *Asplenium alatum* (stove), *Adiantum dolabriforme* (s), *Davallia Tyermani* (s), *D. pentaphylla*, *Nephrolepis davallioides* (s), *N. davallioides furcans* (s), *N. Duffi* (s), *Gymnogramma schizophylla gloriosa* (s), a handsome Fern.

These will require careful attention in the matter of watering. Never allow them to get thoroughly dry during the growing season, for if so neglected they are often spoiled beyond recovery. The best plan is to take them down when dry and soak them in water, so as to ensure thorough saturation of both the soil and the moss, and allow them to drain before re-hanging, especially if there are any plants of a delicate character placed underneath them.

(To be continued.)

EVENTS OF THE WEEK—The meetings of the week include the following—Royal Society to-day (Thursday) at 4.30 P.M., also the Linnean Society at 8 P.M. The Society of Arts meet on Wednesday, May 7th, at 8 P.M. The usual sales at King Street, Covent Garden, and Cheapside will take place.

— **THE WEATHER IN THE SOUTH** has been generally spring-like, though still rather unsettled. Considerable rain has fallen, and the effects are seen in a rapid growth of outdoor vegetation. Slight frosts have occurred in some districts, but no serious damage to fruit tree flowers seems to have resulted so far. We hear from one grower who has between eighty and ninety acres of Plums, that the prospects of a satisfactory crop are encouraging. On Saturday in the metropolis a remarkable darkness following a very bright early morning lasted until past midday with heavy and continuous rain. Tuesday was very bright.

— **THE WEATHER IN THE NORTH.**—April 21st-23th. The week has been cold throughout; dull and showery for the first few days, brighter and with cold N.E. winds latterly. Some heavy hail showers occurred on the 25th; the hailstones in the north of Perthshire are reported to have been of unusual size. Heavy rain fell on the evening of the same day for several hours. This has done much good: 1½° of frost registered last night.—B.D., *S. Perthshire*.

— **WEATHER AND FLOWERS AT SHEFFIELD.**—Mr. B. Simonite writes laconically:—"The weather is most vile here, cold and dark. The flowers cannot open. Ten minutes' sun in a fortnight."

— **WE** are informed that MR. STUART H. LOW, the principal member of the firm of Messrs. Hugh Low & Co., nurserymen, Upper Clapton, died on April 22nd, aged sixty-three, after a short illness. The deceased gentleman has long been widely known in the horticultural world, and assisted greatly in the development of a large business.

— **THE BRITISH FRUIT GROWERS' ASSOCIATION.**—The Duke of Bedford has contributed £25 to the British Fruit Growers' Association to open a fund for the purpose of preparing and publishing an official report upon the present condition and prospects of fruit culture in Great Britain and Ireland.

— **NOBLE STRAWBERRY.**—This Strawberry is simply not to be surpassed as a forcing variety to ripen now (April 21st). I have a shelf which would be hard to beat for crop and size of fruit, and another year I shall rely principally upon it. Sir J. Paxton put into the same house a month earlier is ripening at the same time a much lighter crop. I have not tried Noble for early work.—H. S. EASTY.

— **THE SPARROW PEST.**—I am made to say under the above (page 327), heading, "Of course it is always necessary to net small birds." It should have been "to net small seeds" as a protection against sparrows and the finch tribe, for the reason that some persons complain of the ravages of birds, and at the same time take no trouble to prevent them, as apart from the damage done to seed beds most of the finches destroy large quantities of caterpillars, as well as innumerable weed seeds, such as Charlock, Thistles, Docks, Dandelion, &c.—R. MAHER, *Yattendon Court*.

— **GRAND YORKSHIRE GALA.**—The thirty-second Exhibition takes place in York, June 18th, 19th, and 20th, when about £600 in prizes are again offered; £42 are devoted to sixteen stove and greenhouse plants, nearly £50 to groups, £48 to Orchids, £100 to Pelargoniums in various classes, £44 to Roses in pots, £55 for cut Roses, £60 for fruits, and many other objects are invited. The York Show is always a grand display, and brings together an enormous number of midland and northern horticulturists.

— **THE EDINBURGH EXHIBITION.**—In connection with the opening of the above Exhibition the Duke and Duchess of Edinburgh left King's Cross on Wednesday morning in the new Royal Saloon for the north. The suite in attendance was Lady Emma Osborne, Colonel the Hon. W. J. Colville, Captain the Hon. D. J. Monson, and Colonel Walker. Sir George Chubb, Chairman of the London Committee of the Edinburgh Exhibition, together with Sir Saul Samuel, Sir John Pender, Mr. Thomas Archer, C.M.G., Mr. E. N. C. Braddon, Professor Forbes, Dr. Robert Hogg of the *Journal of Horticulture*, and other members of the London Committee travelled by the same train.

— **RENOVATING OLD FRUIT TREES.**—In a recent article I advised planting young trees rather than attempt renovating old ones by grafting. My reason for doing so was that many trees on thirty acres of ground were regrafted, but in less than twenty years nearly every tree was dead. The opinion of some was that where the branches had been cut to receive the grafts, the rain entered and caused decay. My opinion is that when a branch is cut the ascending sap is not assimilated, and fermentation takes place, which causes decay. Whether any of us are right or wrong, the trees operated on died, while in a young plantation made later the trees are in a healthy and profitable state, as are some resuscitated by deluging the ground with sewage in winter.—W. T.

— **HORTICULTURAL CLUB.**—A complimentary dinner of welcome was given by the Club on Tuesday evening, 22nd ult., at the rooms, Hotel Windsor, to Messrs. David Thomson of Drunlanrig and Bruce Findlay of Manchester on the occasion of their receiving the Veitch Memorial medal. In the absence of Mr. John Lee the chair was taken by Dr. Hogg, and there were present besides, the Rev. W. Wilks, Messrs. D. Morris, Bunyard, H. J. Veitch, J. H. Veitch, Cheal, Dismoor, Walker, Druery, Hore, Bull, G. Paul, Crowley, A. F. Barron, H. J. Pearson, A. H. Pearson, Turner, &c. Amongst the guests were also Mr. F. W. Burbidge and Mr. S. Barlow. The toast of the evening was proposed by the Chairman, and responded to by Messrs. D. Thomson and B. Findlay. During the evening a selection of vocal and instrumental music was given, under the kind superintendence of Mr. Bunyard. The health of the other visitors was proposed by the Secretary and responded to by Mr. F. W. Burbidge, whom the Secretary claimed as a fellow graduate of the same University. Mr. Morris replied on behalf of the Royal Horticultural Society. Mr. Shirley Hibberd in kindly terms proposed the health of the Chairman, and the meeting

was altogether one of the most successful gatherings the Club has ever held.

— **THE GARDENERS' ORPHAN FUND.**—The Executive Committee of the above Fund met in the Caledonian Hotel on Friday last, April 25th, at 6 P.M., C. H. Sharman, Esq., in the chair. Mr. A. F. Barron stated that he had received a letter from their Chairman, Mr. G. Deal, who was still too unwell to attend, but he was recovering slowly. Much regret was expressed by the members, and the Secretary was instructed to convey to Mr. Deal the sympathy of the Committee, with a hearty wish for his speedy restoration to health. The principal business was to consider the nominations for the eleven vacancies at the next election. After careful examination of the respective cases, the Committee admitted eleven fresh nominations in addition to the six unsuccessful at the last election. The distribution of the voting papers was discussed, the Secretary remarking that many subscriptions were still unpaid, and it was resolved to send notices to all who are in arrears. Mr. Barron was instructed to make the necessary arrangements for the acceptance of the completed Wildsmith Memorial Fund, and the election of the child nominated by the local committee. At 8 P.M. a joint meeting of Covent Garden Market representatives and members of the Orphan Fund Committee was held, to consider the arrangements for the evening fête to be held in the market on May 21st.

— **THE WEATHER AND FRUIT PROSPECTS IN THE NORTH.**—Since the thunderstorm on April 6th the weather has been variable and unsatisfactory. Severe frosts, high winds, accompanied with heavy rain and hail showers, have prevailed. Where the birds have not injured the blossoms the Plums are covered, but the hail on the ground is not cheering, and from the severity of the weather not a bee can reach the blossoms. Apples and Pears have a scarcity of blossom, and some are greatly under the average, but with finer weather an average crop might set, but it is too early to be able to form an opinion. Fine weather is much needed in the orchards of Clydeside.—BLANTYRE.

— **SUCCESSFUL MUSHROOM BEDS.**—At Thames Ditton House, Thames Ditton, the residence of W. F. Hume-Dick, Esq., we lately saw two beds of Mushrooms that are worthy of note. The top bed, 9 feet by 2 feet, was spawned on January 24th; first Mushrooms cut March 8th. Since that time the bed has averaged quite 8 lbs. per week, being at times covered with splendid Mushrooms of a good useful size, and often with from twenty to thirty in a cluster. The under bed was spawned on March 1st; Mushrooms cut April 18th. A grand lot of rather larger size than in the top bed, one example measuring 6 inches across. Temperature kept 58° to 60°. Mr. W. Palmer, the gardener, said he obtained the spawn from Reading, and he has certainly made good use of it.—J. B.

— I HAVE posted to you this evening a rather interesting specimen of the WHITE-FLOWERED NATIVE FRITILLARY. Fasciation is frequent in this genus, notably in *F. imperialis*, but in this particular case there is exhibited in a floral freak a singularly pretty arrangement of the four blossoms and foliage that terminates the stem. Monstrosities are not usually of a pleasing form, but this one may be considered an exception, and has been gathered from a cultivated clump of them, the remainder producing normal flowers.—J. E. JEFFERIES. [If the variety prove constant it will be well worth increasing. There is a fasciated variety of *F. imperialis*, sold by Dutch growers under the name of *Slagzwaard* (Sword-stemmed) said to be quite constant.]

— **STAPHYLEA COLCHICA.**—This plant, so useful for flowering during March and April, succeeds well on its own roots. Cuttings can be taken when the growths are half ripe, inserted in sandy soil and plunged in gentle bottom heat. In two years' time capital little plants will be available if their treatment is liberal during growth, and when in flower they will be useful for filling small vases. Plants which are grafted upon some stock are often much too tall to look well. Those grown from cuttings and "pinched" occasionally, make compact bushes. Much root space is not needed; 7 and 8-inch pots are large enough for good sized plants for several years, provided they are assisted during growth with weak liquid manure. Its freedom from insects is a special mark in the favour of this plant. I have only seen red spider on the leaves caused by allowing the soil to become too dry.—E. M.

— **WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.**—This Society continues to flourish and grow larger. Two meetings have been held during the past month, which were both well attended. On the 9th inst., R. Walters, Esq., in the chair, a

capital paper was submitted to the meeting by Mr. W. Osborne on "Potatoes." The essayist dealt with his subject in a plain and practical manner. It was highly appreciated by the members present. A good collection of Potatoes were staged by Messrs. Fulford and Adams. The usual vote of thanks terminated the meeting. On the 22nd inst. Mr. G. Fulford occupied the chair. There was a very good muster of members and visitors present to hear a paper on "The Greenhouse and its Occupants," by Mr. W. King. A lengthy discussion arose, to which Mr. King replied. A group of *Azalea mollis* and *Spiraea* was staged by Mr. Riding. Some Pansies were also exhibited by Mr. Gull of immense size. The vote of thanks to the essayist, and a similar compliment to the Chairman, ended the meeting.

— **TASMANIAN APPLES.**—Mr. James Webber, Central Avenue Covent Garden, has sent us samples of Ribston Pippin and King of the Pippin Apples. The former are of full size, fresh, firm, and of the first quality, reminding in tenderness and flavour of orchard house grown fruits. The King of the Pippins are of fair size for the variety, very clear, juicy, and sugary. We have to note, however, that this is not the variety usually grown under the name in this country, but is the true old King of the Pippins, or King Apple of Rea, now rarely seen; and it is singular that it should come to us from the antipodes. It is a smaller, earlier, and richer Apple than the Golden Winter Pearmain, which is the correct name of the free and useful variety generally grown as King of the Pippins. This is of continental origin, and was invested with the name which adheres to it, by a nurseryman, long since deceased, for trade purposes. Good Tasmanian Apples such as those referred will be acceptable to many persons at this season of the year.

— **LATHYRUS SIBTHORPI.**—You will be interested in knowing that I have just lighted on a communication written in 1836 by William Baxter, in the "Gardeners' Magazine," relating to *Lathyrus Sibthorpi*. It appears to have been cultivated in the Oxford Botanic Garden prior to 1795, singularly enough under the name of *L. rotundifolius*, yet the plant introduced and cultivated under this name since 1822 is alleged to be its parent. The "Annals of Botany" (König and Sims, vol. ii., page 451) contains an account of it, but I have not yet had an opportunity of referring to it. Bieberstein it is supposed introduced it, presumably during the time of the second Sibthorp, the author of the "Flora Græca." Vexation and sorrow flow with the ink here, for much of the voluminous correspondence of Dr. John Sibthorp was, after his death, disposed of by his "friends" as waste paper. The *Rosa ferox* now in the garden is that of Bieberstein, and is perhaps the only one in this country of the kind, and I think very probably were sent as seeds with the *Fritillaria racemosa* and the *Lathyrus*, from the coast of the Caspian by him to Dr. Jno. Sibthorp, but this is speculation.—JNO. E. JEFFERIES. [The "account" in the "Annals of Botany" is a mere fragmentary allusion, and imparts no fresh information on the subject.]

— "VISITOR'S" note respecting *LACHENALIA PENDULA* being so beautiful when growing in a basket at Childwall Hall Gardens leads me to say that *L. tricolor*, with smaller flowers, also forms a capital basket plant. The three colours in the flower—green, red, and yellow—are exceedingly distinct when a good base of its foliage is provided, which droops in a naturally graceful manner. When baskets of the size named by "Visitor" are used it is not necessary to disturb the bulbs every year if fairly good soil be used at first. They will succeed for the second season's flowering with the assistance of some stimulant when growth is well on the way, especially when the flower spikes are forming. I do not know a better plan to show the blooms of *Lachenalia* than growing the plants in baskets. From the time the foliage turns yellow after flowering is past no water should be given until the following August. If the baskets are hung in a cool shed, say one with a northern aspect, the mass of soil in baskets of the size named will retain sufficient moisture to carry them through the resting period.—H.

— **DOUBLE PRIMROSES.**—These are very useful for producing an early display out of doors either in the beds by themselves or in the front of herbaceous or shrubby borders. In the latter they are perhaps the more useful. They do not require replanting so often as when in beds, and they succeed much better when the roots are left undisturbed for two or three years. When they are employed in the beds along with other spring flowering plants the fault of double Primroses is that they flower too soon. Much depends upon the natural soil of the beds or borders. A cold wet position does not suit them. A warm sandy soil made rich with manure produces robust growth and insures

freedom of flowering. The earliest variety to flower is the mauve purple *platypetala plena*, which does not grow more than 6 inches high, opens its flowers early in March, and continues to do so for nearly three months. *Lilacina fl.-pl.* produces deep lilac double flowers in great profusion. This is more robust than any other. The old *alba plena* needs no praise to recommend its qualities, which are well known. Where the yellow sort thrives it is a desirable plant to encourage, because there are few flowers of its colour to be had then. The best time to increase the stock is in May, when flowering is over. Every single crown with a root attached will grow if planted in a suitable position. A north border answers well, where they will obtain shade for a time until new roots are formed.—E.

— EFFECTS OF FROSTS UPON BROCCOLI.—It is a curious fact but which I have frequently noted, that the youngest Broccoli plants are usually the least affected by frosts. Last year we prepared an exceptionally strong yet most sturdy lot of plants from which great things were expected. All were given abundance of room, and the ground being firm and fairly rich, extra stout stems resulted, or such as only unusually severe frosts would cripple. Apparently these stems are quite uninjured, but not so the leaves. First very severe hoar frosts much injured the young central leaves, and subsequently the older leaves also gave signs of collapse, very little green being left in them. At the present time the greater portion of the plants look much as if they had been scorched by fire, and rustle in the wind like leaves on trees in the autumn. Not more than a dozen plants were killed, and we shall have hearts from all that survived, but they are or will be less than half their usual size. Not many yards from this quarter a number of plants were put out a month later on ground just previously cleared of Strawberries. These made but poor progress at first, but grew considerably in the autumn. They are not nearly so sturdy as the older plants, being taller when put out, but not one has been killed, and only a very few leaves lost, the majority being quite green and healthy, while the hearts we have already cut have been of a useful if somewhat small size, and of excellent quality. I do not profess to be fully able to explain why the young, and what we might reasonably assume the most tender, Broccoli plants should escape while the apparently most matured plants suffered badly, but merely chronicle the fact that such is really the case.—W. IGGULDEN.

— THE ANCIENT SOCIETY OF YORK FLORISTS recently held its first show of the season at the Guildhall, York, the public being as usual admitted free, a privilege of which a large number of people availed themselves. The arrangements were admirably made by the members of the Committee. Over 500 specimens were staged by some twenty exhibitors. The display of Hyacinths was exceptionally fine. All the blooms were of good quality. There was a fair average collection of varieties of Auriculas, good Tulips (in pots), and excellent specimens of Polyanthus Narcissus. The new rules of the Society for restricting Auriculas and Polyanthus to pots not exceeding 4 inches lent uniformity to the exhibition. In cut flowers the hand bouquets, gentlemen's buttonholes, ladies' spray bouquets and bunches of flowers were much admired. The chief winner in the classes for Auriculas and Polyanthus was Miss Steward, other awards being gained by Dr. Baker, Mr. T. Smith, Mr. G. Cooper, and Mr. G. Hudson. Mr. S. Hardcastle, Mr. J. Nicholson, Mr. B. Pannett, Mr. Fielden, Mr. W. Douglas were also winners in these classes. Dr. Baker took all the first prizes for Tulips and most of the premier honours for Hyacinths, including a prize given by Messrs. Clues Bros., of 23, Market Street, for six Hyacinths dissimilar, Miss Steward and Mr. E. Gray being second and third. Miss Steward, Mr. W. Douglas, Mr. Fielden, and Mr. Leadley took prizes in Hyacinths. Mr. S. Hardcastle, Dr. Baker, Mr. W. Heppell, Miss Barstow, Miss Steward, Mr. B. Pannett, and Mr. J. Nicholson shared honours in the classes for Primulas, Cyclamens, Cinerarias, Spiræa, stove plants, &c. Other awards went to Mr. M. Dyson, Mr. H. E. Wilkinson, Mr. G. Horner, Miss Kirlew, and Mr. W. Heppell. The next show will be held at the Guildhall on May 28th.

— MR. RICHARD DEAN AND THE EALING HORTICULTURAL SOCIETY.—A copy of the *Middlesex County Times* has been sent to us containing the report of a presentation of a gold watch and a purse of gold to Mr. Dean in recognition of his services rendered to the Society during a period of upwards of twenty years. In another column of the above paper he gives a short lecture to the members of the Gardeners' Improvement Society, and makes a suggestion worthy of their consideration. He says:—"The Gardeners' Society professes to be an organisation for mutual improvement; yet but very few of its members contribute information for the benefit of their fellow members; they

prefer to compete for prizes rather than writing and reading papers at their ordinary meetings—doing for gain what I think they should do for the love of knowledge, and a desire to impart it to others. The readers of papers at the weekly meetings are mainly from the outside—gentlemen who put themselves to some expense and trouble to undertake what is asked of them. The best educational test would be, when a paper is read—such a one, for instance, as that by Mr. Hudson, on the culture of Grapes—the members should prepare an abstract of the paper, and send it in on the second day after. This would require close attention to the reader, the practice of note-taking, and the exercise of the useful power of condensation in compiling an abstract, which should set forth the main argument and method of the reader. This would encourage mental concentration, cultivate the memory, impart the faculty of summarising, and lead up to the capacity of writing for the Press—all solid educational advantages of a very high order and value. If the young members could be induced to keep a common-place book, in which to set down under appropriate headings, and arranged for ready reference, such scraps of information as they can gather up at the meetings of the Society, they will have much reason to rejoice in after life. It is by such means as I have indicated that so many gardeners have risen to foremost positions on the horticultural Press."

HONOURS TO HORTICULTURISTS.

SUGGESTIONS have been repeatedly published in this Journal during recent years with regard to the desirability of bestowing a proportion of the medals at the disposal of societies and others upon general horticulturists of note outside the ranks of the exhibitors. The Veitch Memorial Trustees gave some attention to this matter last year, with the result that one of their medals was awarded to Mr. A. F. Barron, who well merited the public recognition of his services. This year the Trustees selected for similar honours two northern representatives of horticulture—namely, Mr. David Thomson of Drumlanrig Gardens, and Mr. Bruce Findlay, Curator of the Manchester Botanic Gardens. As recorded in our last issue, the presentation to these gentlemen was made by Sir Trevor Lawrence, Bart., M.P., at the meeting of the Royal Horticultural Society on April 22nd, and the hearty applause with which the recipients were greeted proved convincingly the general opinion as to the honours being correctly bestowed. The awards have, in fact, given much satisfaction, and the action taken by the Trustees in departing from conventional methods has secured general approval.

MR. BRUCE FINDLAY.

As the occasion is a suitable one, we reproduce a portrait of Mr. Bruce Findlay, published in this Journal nine years ago on the occasion of the great International Horticultural Exhibition in Manchester. It is still, however, a faithful likeness, as the lapse of time has but little altered Mr. Findlay's appearance, and certainly does not seem to have decreased his characteristic energy in the slightest degree. The following is an abstract of what previously appeared in these pages regarding Mr. Findlay and the garden over which he presides.

The original proposal to establish botanical gardens in Manchester appeared in 1822. There were then very few establishments of the kind in England, but there was one at Liverpool, and it was in order to be on a par with the last-named that the proposal for a Manchester garden was issued. But the project was mooted before its time. Nobody cared to take it up, and not until about 1829 was it started anew. A Botanical and Horticultural Society was then established. Dr. Dalton went all round the suburbs of the town testing the comparative cleanliness of the leaves of the trees with a cambric handkerchief, so as to be sure of the purest atmosphere, and this being found at Old Trafford, the existing site was chosen. In 1831 the gardens were ready, and about midsummer that year there was a grand procession and an opening exhibition. With the original Curators we need not here concern ourselves. They were estimable men—Mr. Findlay's immediate predecessor, the late Mr. Campbell, was one of the most genial gardeners that ever lived. Mr. Findlay himself came upon the scene in 1858. He was born at Streatham in Surrey. Some of his earliest experience, we believe, was gained in Rollisson's nurseries at Tooting. When he received the appointment he has now held with so much credit he was only twenty-three years of age. Flower shows, when Mr. Findlay came to Manchester, were for the select few, the connoisseurs in plants, the fashionable and the wealthy. Taking up with his accustomed promptitude the capital idea set forth in the Great International Show at South Kensington in 1866, he determined that

with proper support Manchester, through his personal effort, should be the first to follow suit. In Whitsun week 1867 began, accordingly, those splendid flower festivals we now look forward to as an integral part of the year's enjoyment. Mr. Findlay has been instrumental in promoting public enjoyment in a rational manner to a degree it would

had permitted, to be one of the foremost horticulturists of the day, and one of the best cultivators in Great Britain. Frequent testimony to his skill has appeared in these pages from visitors to the establishments under his charge, but more particularly during the past twenty years, to the princely and beautiful-situated Drumlanrig. It has

FIG. 53.—MR. DAVID THOMSON.

be difficult to over-estimate. That he does his work in the calm and business-like way that best commends a man to his friends is proved by the way in which they constantly and uniformly rally round him.

MR. DAVID THOMSON.

In his brief, pithy speech when returning thanks for the presentation of the medal, Mr. D. Thomson said he could only claim to have been "a successful servant;" but he might also have claimed, if his modesty

evidently been the rule with Mr. Thomson to strive for the best possible results with everything he has undertaken, and his efforts have been rewarded by a very large measure of success.

We can only give a brief review of Mr. Thomson's career as a gardener and author, but it will suffice to show his activity and constant application to work. He was born in 1824 in the Island of Mull, to which place Sir Walter Scott had sent Mr. Thomson's father as land steward in 1816. He was apprenticed at Carstairs House, and soon gave

evidence of his ability, for he was promoted as journeyman some time before the expiration of his apprenticeship. From there he went to Bothwell Castle, under the veteran Mr. Turnbull, where he remained about four years, and then came to Regent's Park under Mr. Marnock, chiefly with the object of seeing horticulture as practised in and around London. He next removed to Wrotham Park, Barnet, then under the management of his brother Mr. William Thomson, and Mr. D. Thomson attributes much of his after success to the experience he gained at Bothwell Castle and Wrotham Park. His first charge was as gardener and general manager to Mr. Drummond, then head of the banking firm at Charing Cross. After two years' service there he left, much to the disappointment of his employer, and took charge of the gardens at Dyrham Park. It was there that such important work was performed in transforming a strong yellow clay into a fertile soil by an elaborate process of burning which has been described in this Journal. After eight years' residence at Dyrham he left, again with great reluctance on the part of his employer, and took charge at Archerfield, near Drem in East Lothian. These gardens he rendered celebrated for flower gardening and fruit culture, Pines and Grapes were admirably produced, and his ten years' work added materially to his fame as a cultivator. Leaving there he entered on his duties as head gardener at Drumlanrig Castle in 1868, under the late Duke of Buccleuch, and there he has performed most valuable services, remodelling the glass, and proving in every department his skill and experience as a gardener.

Mr. D. Thomson has also done good work as a writer and author, his treatises on "The Pine Apple," "Fruit Culture under Glass," and the "Handy Book of the Flower Garden" being standard works in a horticultural library. He also began writing for the Press when twenty years of age, and for twenty-five years he was a constant contributor to "The Scottish Gardener" and "The Gardener," and for some years he edited the latter. For a considerable period he has been a contributor to the *Journal of Horticulture*, and his writings are always appreciated for their practical useful character.

There is little to add except that a public recognition of Mr. Thomson's merits was accorded him a few years since in the award of the Niel prize in the north, and the Veitch Memorial medal may therefore be said to be a corresponding testimonial from his southern friends and admirers.

THE REVISION AND CLASSIFICATION OF THE PICOTEE CLASSES.

BY THE REV. F. D. HORNER AND MR. E. S. DODWELL.

IN my paper on pages 34, 35 of our Annual Report, I have given my reasons for the note appended to the yellow ground section in our last schedule of prizes, and the objections, as they appear to me, lying against the existing system followed in the case of the white ground Picotee. "Colour being the rule of selection, we reject arbitrarily and barbarously, in the case of the Picotee, every hue or combination of hues not distinctly either a red, or purple, or salmon, pink, or rose. And, subdividing the colours into heavy edged and light edged sections, we leave out, and make of no account, the whole of the medium or feather edged varieties;" that is, in the case of the single bloom classes.

It appears to me that this is most unsatisfactory, and to threaten, as it is extended, yet more undesirable results. Fifty years since we had two classes in Picotees for single blooms. We now have six, and I observe, from the copy of the schedule of prizes sent me, our friends of the National Carnation Society extend it to eight, without, however, covering the objection I have referred to as the medium edged class, or including every hue or combination of hues developed in the flower. Resting upon colour it is exclusive, and unless we are to set up classes for every shade, a *reductio ad absurdum*, will ever remain so.

I propose, therefore, in the case of the white ground Picotees, to rest the division upon the breadth of the marginal colour—an easily understood and perfectly feasible arrangement in the case of the curvilinear edged flowers, and dropping all requirement as to colour—to offer prizes in three divisions: (1) broad edged, (2) medium edged, (3) light edged. We may thus do away with the reproach of hard and fast lines of exclusion, sometimes, and in this case justly as it appears to me, laid against us, and adopt a rule which, whilst allowing every hue or combination of hues in the flower to be brought forward, would require the selection, not to depend upon the preference of individuals for particular colours or shades of colour—a subject upon which tastes may legitimately differ—but upon well defined and well understood intrinsic merits. Of course this proposition touches only the curvilinear edged flowers. Longitudinal markings rest upon a very different principle; therefore, in place of the regularity of marking so harmonious in the curve, we have the marvellous variety of Nature for our guide.

I shall be glad to hear from you at an early date, and to be advised of any point you may think germane to the subject.—E. S. DODWELL.

MANY thanks for your leaflet on the "Revision and Redivision of the Picotee Classes in Single Blooms." At present, there is to the

medium edge, no *locus standi*, except among the heavies, where it is practically a weaker vessel—a light heavy, so to say—and, therefore, of short weight. As things are, we cannot give this style of Picotee its fair expression, and so I think the main divisions in single blooms might well and happily be heavy, medium, and light. But I would certainly, by no means whatever, run all the edge colours together. It would, I think, be too much centralisation; and single blooms, classed only by depth of edge, would be unwieldly, perplexing masses, incapable of sufficient gradation and recognition in awards, except by some such inordinate length of class prizes, that all attempts at comprehending the magnitude of the prizes at planetary distances from the first, would be vain. The colours of the edges are great natural divisions, forming very easy bases of distinction on the whole. Some tints, indeed, so verge and merge that two descriptive names are better than one—*c.g.*, "rose or salmon edge"—but this, I think, would be less confusing than mixing up one type of marginal breadth in "compôte" of all the colours that edges come. I think that your resting "division upon the breadth of the marginal colour" would rather give scope for, than put restriction upon, "the preference of individuals for particular shades of colour." In a mixture of all the colours in a class constituted alone by depth of edge, there would simply be the fullest opportunity for a judge to side with his favourite edge colour. Whereas, with each type of colour separate in its own type of depth in edge, there is none but the safe choice of "Hobson" possible, so far as colour goes. If we get a new colour—say, blue (!)—let us have heavy, medium, and light-edged blues if they arise. I do not take you for one to be frightened by the "arf-a-brick" charges of exclusivism heaved at us as florists. Never mind what the outer critics say. What they call exclusive, we term distinctive. I think decided edge colours in Picotees are more satisfying than nameless blends, just as in the Auricula we disfavour the "undecided edge," and in the Tulip the "rosy bybloemen," as being variably between two classes, and weak flowers in either. The Ranunculus, I know, is hardly ever wrong in colours; but she has peculiar class colours in her 'roans' and 'olives,' capable of wide classification. (I don't know, how "roan-edged" Picotee would sound or look!) Far am I behind you in familiarity with varieties of the Picotee—past and present, new and old. But I fancy there are not many that could not be classed under the existing types of colour: and that, if these were given a triple expression by depth of edge, as heavy, medium, and light edged flowers, in purple, red, and rose edges, we could adequately classify the Picotee as we have it. As for myself, I grow only more and more "hard and fast" in many florist ways. I would, and do seek new developments, and none would more warmly appreciate some new type of beauty, "on well understood intrinsic merits." Only I cannot away with un-florist forms of florist flowers, as ranking with and among florist flowers. That is the point. They are right and pretty among themselves; and in "a flower show," as generally understood, they would be a legitimate feature. But in special shows of a special society, for the development of a flower in special lines of its beauty, it seems to me to be idling with our time and space to introduce flowers that are beside the mark, or simply represent the shortcomings in our efforts. In this light they irritate my eyes as would an ill-spelt word, or a piece of execrable grammar! I fear and feel I don't quite "pan" with you and Brother Barlow on this point. Well, never mind me! I will go and be "hard and fast." It may be sterner work, but the opposite would be more melancholy to me, even from the impression I have never forgotten of seeing an old florist so enamoured and lost amid the bewilderment of keeping nearly everything he raised, for the sake of some point of beauty, that he did not know at last when he had a bad one, and saw nothing better in the best flowers at the National Show than he had in many a hundred truly weak sorts. But here is a long yarn—let me wind it up!—F. D. HORNER.

THE SPARROW PEST.

You ask on page 300 if anyone can say how to get rid of the sparrows, and one asks if they can be poisoned. In dealing with the matter, it cannot be too strictly borne in mind that it is felony to lay poison, to destroy any wild bird or wild animal outside a covered building. The reason of this law will be apparent when it is remembered that the poison might be eaten by a stray dog, fowl, pigeon, hare, rabbit, &c., and might lead to a family of persons being poisoned.

The main reason sparrows have increased so enormously in the past few years is on account of the "Wild Birds Protection Act," of which the public are annually reminded by a certain Society, on all the walls of the country, and the penalties persons are liable to who take or kill, or attempt to take or kill, or have wild birds in their possession; but they do not say what birds are protected and what are not, therefore let it be remembered that sparrows are not included, and, moreover, any person can take or kill any protected wild bird on land in his own occupation, or instruct anyone else to do so.

Now, whatever may be said in favour of sparrows, they certainly are not insect eating birds; they live entirely on seeds and vegetables. It is against their nature to do otherwise, as may be seen by the shape of their bills. They do some good in eating a quantity of weed seeds, but this is about all, and as a natural result of their feeding they are about the most toothsome article I know of, and this brings me to the "key" for their extermination. In London we find in every part eel pies, lark pies, and pork pies, in fact pies made of everything but sparrows. I believe that if sparrow pies were included there would soon be such a

demand for sparrows the British supply would soon be exhausted. To begin, make some arrangement with a London pie shop to take the sparrows. They might be sent ready dressed, which is a very simple and easy matter. A conspicuous card asking customers to "try sparrow pie" would soon work wonders and cause other shops to demand sparrows. Then when once there is a demand for them, and money to be made in supplying that demand, sparrows will begin to have a bad time of it. It is no use trying to exterminate them single-handed, the stoutest heart would soon faint with "all work and no pay," but when they are worth so much per score and the price pays to catch them, the case is quite different, then there will be no lack of catchers.

To capture sparrows I know of no plan to equal putting up boxes in the trees or gable ends of buildings, with a perch in front of a little round hole. In summer they will nest in these boxes and roost in them in winter. Over these holes trap wires can be arranged, so that birds may enter but not get out again. These wires should be so contrived that they may be fixed securely, so that the birds may go in and out freely until sufficient are using the boxes to make a good haul to fill an order. When nesting leave the old nest, other birds will quickly take to it; in fact no other bird so readily takes to or appropriates another's nest.

Another way to take sparrows is by means of a net stretched on a light square frame, with a lot of "pockets" in the net, *i.e.*—baggy places in the net for the birds to drop in; this is fixed to a light pole, and is taken at night, and "clapped" on a stack side, or the Ivy on the walls of a building, and raked down. The least touch on the Ivy or the stack side causes the birds to bolt out against the net; a little to and fro movement causes them all to lodge in the pockets in which they are caught, when a fresh place is tried. If horizontal bars are run across the frame the net may be drawn up in folds and attached to them, forming very good "pockets." I have caught very many sparrows by means of a riddle fastened to the prongs of a hay fork. This works fairly well on a stack side but is practically useless on Ivy. Netting them at night is the easiest and quickest way to catch them, and if well followed up would soon exterminate them. One winter's day, when the ground was covered with light frozen snow, I tried some wire mouse traps, they cost 1d. each, two similar jaws of semicircular wire sprung together by means of a coiled brass spring, a piece of wire stood up for the bait. I could thus bury the traps in the snow, leaving the bait, a bit of bread crust, just on the top of the snow. I then placed a large crust of bread close to it on purpose to attract sparrows flying over at a distance. I caught about sixty in this way in two hours, not one of which touched the large piece of bread, but every one took a fancy to the piece he could fly away with; the trap broke the necks of every one, and they were dead in an instant. At last a robin came and was caught, then I dropped that mode of catching. If the traps had large jaws, and the sides covered with a light net, I think the birds could all be caught alive, then if a robin or other bird got in it could be liberated. There is one fault about the traps I refer to—namely, if the brass springs get wet they break, rendering the trap worthless.

There are people who will not believe a word against sparrows. One farmer I once spoke to would have it that the flock of some 10,000 sparrows that were picking out the half-ripe grains from the ear were only picking off the insects. He would have it that the "filth" had taken the corn. Another one I know does all he can to protect them. His houses are covered with Ivy, in which they nest in summer and roost in winter; but even these would have little chance if captured sparrows had any value.—J. HEWITT.

ROSES IN 1889.

WHAT a perennial fountain is the Rose! What streams of enjoyment, of gossip, instruction, and—twaddle flow from it, and yet there is always something we like to hear about. Perhaps, as Montesquieu says, we are not a little gratified at the failures of our friends, although we do not allow that we indulge so unaimable a thought, and we only are glad that we are not the only instances of failure, while the peculiar behaviour of some old friend somewhat astonishes us.

I commence with failure, because I had a most conspicuous instance of it in a few, very few, Roses that I grew, or attempted to grow, in pots, so as to give me blooms in the house before those on the walls favoured me with their flowers. I think I almost deserved failure for making the attempt. My house is a small one, in which I grow all manner of things, and consequently was too crowded for the plants. Moreover, as I was obliged to keep up fires at night on account of frost, and did not wish to keep them going during the day, there was too great a difference between the day and night temperature, and, as a consequence, the plants got smothered with mildew, and hardly a bloom came to any good. They were Teas, of course, and therefore my failure was the more conspicuous. That I am right in attributing it to this cause is to me pretty clear, for I this year adopted a different plan. I placed them in my annexe, where there is no heat, where the variations of temperature are not so great. They are free from mildew, and are coming now into bloom. It is in

this place that I have my plant of *Maréchal Niel*, which is still vigorous. I cut last year about 300 blooms from it, not large and high-coloured as a plant allowed to have plenty of space would have, but still pretty and presentable blooms, although somewhat pale in colour.

The Longworth Rambler on the south wall of my house has again asserted its claims to be one of the, if not the, very best of dark climbing Roses that we have. It was profuse in blooming, and kept up its flowering until very late. Of course it does not fulfil the condition of an exhibition Rose, and is no doubt a Hybrid Tea, not so large in its flowers as *Reine Marie Henriette*, better in its foliage, the profusion of its blooms, and the absence of lateness in its colour. I am somewhat quaking for *Rêve d'Or* on the east wall of my house. It was so cut back a few years ago that I despaired of it. It, however, sent out shoots from the bottom, and has gone up a good part of the old place it used to cover so well. For some cause or other, however, it was not happy last year, and I am somewhat anxious about its future. William Allen Richardson on a wall facing about S.S.W. disappointed me; indeed I think that a wall is hardly the best place for it, as it seems to take the colour too much out of it, and it loses that beautiful orange tint which has won for it so much favour. Of other Roses on this wall I may mention that *Lady Castlereagh* promises well as a good grower and a useful Rose, that my plants of *Comtesse de Nadaillac* have nearly reached the top, and that I find both *Emile Dupuy* and *Claire Carnot* useful. The former is one of the Dijon group, and described as a *pa'e fawn*. Well, you may make any description you like of these Dijon Roses provided they have some shade of yellow. I think, however, that *Emile Dupuy* is less inclined to quarter than many of them, and it is this confused centre that takes away from the value of the race. *Claire Carnot* is of a very soft pleasing shade of yellow, with a tint of copper in it. It is a *Noisette Tea*, and valuable as a garden Rose.

I do not like to say much on the behaviour of my Roses for the simple reason that I do not consider my soil a good Rose soil, and because I do not give them fair play from an exhibitor's point of view. I grow them too close, and I keep them too long in the same ground. This arises from necessity, not will. I like to grow a good many so as to be familiar with them, and to give place for new Roses each year. I think Teas do best with me, but it is true, as your correspondent Mr. W. R. Raillem in his delightful notes on Roses says, that many of them do not succeed as dwarfs. Certainly I have seen the finest flowers from dwarf standards, but I always thought that most free growing Teas did as well on dwarfs as in any form; and Mr. Prince amongst nurserymen, Mr. Burnside amongst amateurs, are instances of what may be done with dwarf Teas, from which most of their grand blooms are shown. There are several new Roses in this class which, while invaluable for exhibition, are yet from their colouring most desirable for the garden and for buttonholes or sprays. What can be more lovely than *Ma Capucine* (an old Rose)? and lately we have had *Princess de Sagam* and *Marquis de Vivens*. The former is of a dark shade of crimson, rich and velvety in colour, good in habit and free flowering. All this is admirably set forth in catalogues, but somehow or other the printer has omitted the qualifying clause—not quite full. The latter is also a light Rose, but only suitable for cutting as a bud, for it is very thin. *May Rivers*, when exhibited by the raiser, struck me as a very beautiful flower with a good deal of China blood, and from what I see of its habit it is likely to become a favourite garden Rose at any rate.

I have never known a season when the autumnal bloom was so disappointing. It could not be otherwise with us. We had such a down-pour in October as we have not had for many years, and the Teas which we have always looked to to furnish blooms at that season, only gave us balls of soddened leather instead of flowers. Some few struggled through it all; but they were comparatively few, and these were amongst those flowers which are naturally disposed to come through. Unquestionably the best of all the autumn-blooming Roses I had was *Gloire de Margottin*, somewhat too thin to be an exhibition Rose, and perhaps for this very reason proving so good in autumn. It is most brilliant in colour, evidently showing its parentage *Gloire de Rosamène*, somewhat straggling in habit, suggesting the idea of a pillar Rose, and flowering at every point like a Tea Rose.

Some of the little Polyantha Roses gave me a good deal of pleasure, and where Rose growers can afford space for anything but exhibition Roses they ought to find a place. The same may be said of the single Roses. *Austrian Yellow*, I have at last got hold of it after many attempts, and what a lovely, although, alas! fleeting, flower it is. Then the glowing richness of the *Austrian Copper* is so unlike anything else in its family that the question freely rises—namely, that it is not a Rose. Very beautiful, too, is *Macrantha*, with its large white petals and golden stamens, and although some decry it because of the dark colour of its stamens, *Paul's Single White* is a fine pillar Rose; while the single Polyantha, where space can be given to it, is a most lovely object. *Berberidifolia Hardi* I have not done much with. I do not think that it can be considered hardy; at least, I have lost it once or twice by endeavouring to consider it so. I have had to take mine up and pot it, and I do not think it looks happy under the process.

I was unable to procure some of the Roses I wanted in time to plant this last autumn. They were consequently laid in, the tops protected from frost until the spring. On carefully taking them up I was surprised to find how little root action there was, for I had been taught to believe that roots were very active during the winter. All I can say is that I saw hardly anything of it in either Teas or Hybrids, and as my

soil is light and friable it was just suited to set them off if so inclined. I therefore began to doubt very much whether there is so much of it as stated.

I was asked by a large grower of Roses for sale whether I had ever tried pruning them in the autumn when planted, as it was his opinion that was the proper time for pruning. It was needless for me to protest, but if we get a severe frost will they not be killed? and so I have tried a few in this way, giving them an equal chance with those treated in the ordinary method. The result of this experiment will be a matter for next year's account if I am spared to give it.

Altogether, then, the season to me was, as in most places, a disappointing one, and the "manners and customs" of my Roses were of neither a settled, nor on the whole, a respectable character.—D., Deal.

ROSE SHOW FIXTURES, 1890.

June 19th.—Ryde.

„ 24th.—Drill Hall, Westminster (N.R.S.).

„ 25th.—Richmond (Surrey).

„ 27th.—Royal Aquarium.

„ 28th.—Eltham, Reigate.

July 1st.—Canterbury, Hereford, Sutton.

„ 2nd.—Brockham, Croydon, Dursley, Hitchin.

„ 3rd.—Bath, Farningham, Norwich.

„ 5th.—Crystal Palace (N.R.S.).

„ 8th.—Gloucester, Ipswich, *Winchester.

„ 9th.—*Brigatton, Diss, Ealing, Tunbridge Wells.

„ 10th.—Birkenhead, Worsop.

„ 12th.—New Brighton.

„ 17th.—Birmingham (N.R.S.), Helensburgh.

„ 22nd.—Tibshelf.

*In the case of Brighton and Winchester, where the Shows extend over more than one day, the date of the first day's Show only is given.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

DEATH OF DR. GEORGE THURBER.

THE death of Dr. George Thurber ends the career of the most accomplished horticultural writer America has produced. Dr. Thurber was born in Providence, Rhode Island, in 1821, and early became interested in botany in connection with pharmaceutical studies, which he took up in preparation for his business as an apothecary, which he conducted in his native city. His love of plants, however, was strong, and brought him into relations with Dr. John Torrey, of this city, then the leader among American botanists, and a man whose influence was widely felt. It changed entirely Thurber's career, and secured for him in 1850 the position of naturalist, to which were added the duties of quartermaster and commissary, of the United States and Mexican Boundary Survey. He was attached to the headquarter's party under command of Mr. John Russell Bartlett, the principal commissioner for the United States, and was actively engaged during four years in exploring the natural products of the country between the Gulf of Mexico and the Pacific Ocean. These journeys extended to nearly 5000 miles, and carried the party into regions which were at that time entirely unknown, scientifically. Thurber "was indefatigable," to use Mr. Bartlett's words, "in his exertions to make thorough examinations and complete collections of everything belonging to his department." He discovered many new plants within the limits of the United States and in northern Mexico, where the party made several long and exceedingly arduous journeys. The most interesting of his new plants were published by Asa Gray ("Plantæ Novæ Thurberianæ") in 1854, the name of the discoverer being there commemorated in the new Hibiscus-like plant, *Thurberia thespesioides*, which he had found in Sonora in 1851.

Dr. Thurber, the duties of the Commission being completed, returned to this city and accepted a position in the Assay office, from which he resigned on account of political differences with the authorities, and devoted himself to chemical and botanical studies, lecturing on these subjects at the Cooper Union and before the New York College of Pharmacy. In 1859 he was chosen to the Professorship of botany and horticulture in the Agricultural College of Michigan, a position which he held until 1863, when he became editor of the *American Agriculturist*, of this city. This place he filled with singular success for twenty-two years, when he was compelled by failing health to relinquish the active control of the paper, although he continued to contribute to its columns, and give it the benefit of his counsel until within a few months of his death. Dr. Thurber's influence as editor of a widely read popular journal was great. His writing was characterised always by sound common sense based on exact knowledge of many subjects, and they did more in his time to elevate the standing of the agricultural and horticultural press of the country than the writings of any other man. He possessed a charming style and a rare facility for explaining the most complex subjects in clear and simple language. This gift made the "Doctor's Talks," which he contributed during many years to the *American Agriculturist*, and which were intended to instruct young people upon scientific subjects, models of their kind. Of horticultural matters he wrote out of a full knowledge, as his garden at Passaic, New Jersey, an experimental garden in the true sense of the word, was one of the most interesting in this country. In this garden he found the pleasures of his later years, and these pleasures he shared with the public through his "Notes from the Pines."

Dr. Thurber's editorial work was not confined to the columns of the *American Agriculturist*. The publishers of that journal were large

publishers also of books relating to country life, and most of these passed under Dr. Thurber's critical eye, or, in some cases, were entirely rewritten by his hand. He published, in 1859, "American Weeds and Useful Plants," an enlarged and greatly improved edition of Darlington's "Agricultural Botany," which is still the standard work on the subject, and he contributed the articles upon botanical subjects to "Appleton's Cyclopædia." Dr. Thurber's predilections in botany were for what may be called agricultural botany. This led him to make a systematic study of Grasses, and his knowledge of these plants was unequalled for many years in the United States. It was his intention to prepare a monograph of American Grasses, but editorial duties and failing health, undermined by the hardships of the Mexican boundary, compelled him to abandon this undertaking, for which he was otherwise admirably equipped; and of late years he has been able to do little beyond occasional contributions to the Press.

Dr. Thurber was a man of great knowledge and of the broadest sympathies; kind, faithful and true, generous to a fault, simple in the ways of the world, and always more interested in the welfare of others than in advancing his own interests. His death removes an interesting and picturesque figure, and a man who will never be forgotten by his friends.—(*American Garden and Forest*.)

ROYAL AQUARIUM, WESTMINSTER.

APRIL 29TH AND 30TH.

A BRIGHT, varied, and attractive Exhibition was opened at the Royal Aquarium, Westminster, on Tuesday last, as the second of the series for the present year. Auriculas and Primroses constituted the leading features, but the Daffodils, the Clivias, the Pæonies, the Rhododendrons, and the miscellaneous groups were strongly and admirably represented. The Superintendent, Mr. W. Holmes, arranged the exhibits in an effective manner, and all concerned in the management had ample reason to be satisfied with the results of their efforts.

Some of the most experienced florists did not hesitate to say that the show of these plants was equal in merit to that of the National Society held in the previous week; indeed, in some respects there was an obvious improvement, and the Alpine varieties constituted an exhibition in themselves. A class was provided for a collection of Auriculas, in which there were three competitors, the premier award being secured by Mr. James Douglas, gardener to Mrs. Whitbourne, Great Gearies, Ilford, who had about fifty excellent plants, chiefly of the show edged and self varieties. Mr. C. Turner, Slough, was second, Alpines and selfs predominating, all well grown plants. Mr. R. Patterson, Ashburne Gardens, Sunderliand, was a close third, his plants being slightly smaller, but good, and the varieties chiefly selfs and edged forms.

The competition was also good in the class for twelve show Auriculas, the first honours being secured by Mr. G. Wheelwright, Oxford Road, Reading, who had the following varieties—Mrs. A. Potts, Col. Taylor, C. J. Perry, Rev. F. D. Horner, Heather Bell, Lancashire Hero, Black Bess, Prince of Greens, Acme, Dr. Kidd, Richard Headly, and George Lightbody. Mr. J. Douglas was a close second. Mr. R. Patterson was third, a plant of Heroine being very notable; and Mr. C. Adams, Swallow, was fourth. Only two collections of six show Auriculas were entered, Mr. Henwood leading with good plants of Mrs. Potts, Dr. Kidd, George Lightbody, Rev. F. D. Horner, Black Bess, and Mrs. Dodwell. The second prize went to Mr. Phillips, Reading, a few points behind the first, but with good flowers. Of the six competitors with four show Auriculas, Messrs. Henwood, Wheelwright, Douglas, and Patterson were successful in taking the prizes in the order named.

Several classes were devoted to single specimen Auriculas, and a much better system of affixing the prize tickets was adopted than at the National Show. For green-edged, Mr. J. Douglas was first, second, and fourth with the Rev. F. D. Horner, and Mr. Henwood was third with the same variety. The best grey-edged was Mr. Henwood's George Lightbody. Mr. Douglas being second and third for the same variety, and Mr. Phillips fourth for Lancashire Hero. In the white-edged class Mr. J. Douglas led with Horner's Elaine, he also took the fourth prize with that variety, Mr. Henwood being second and third with Smiling Beauty and Acme. Black Bess was the leading variety in the self class, and secured Mr. Henwood first and third prizes, Mr. Wheelwright taking the second place with the same, and Mr. Douglas was fourth with Tiresias.

As already remarked the Alpine classes were well filled, and the exhibits of a generally superior character. For instance, there were nine competitors with twelve varieties, and the plants with which Mr. J. Douglas secured the first prize were of quite an exceptional character, vigorous without being coarse, the flowers large, clean, and bright. The varieties were Diadem, Mrs. Blackburn, Ada Hardwidge, Miss Moon, Sensation, Toujours Gai (certificated), Hotspur, Nellie Hibberd (certificated), Love Bird (certificated), and some unnamed seedlings. Mr. C. Turner followed closely for the second place, Mr. Wheelwright was third, and Mr. W. C. Walker fourth. Mr. Henwood had the premier six Alpines—namely, Defiance, Mr. Martin, Homer, Mary Francis, Hotspur, and Lovebird, all excellent plants. Mr. C. Phillips, Reading, Mr. R. Dean, and Mr. A. J. Weston, Balham, were second, third, and fourth respectively. Nine also competed with four Alpines, Messrs. Douglas, Henwood, Wheelwright, and Patterson being the prizewinners. In the single specimen classes the prizewinners were as follows:—Yellow grounds.—First, second, and fourth, Mr. Douglas, with Miss Moon and seedlings. Third, Mr. C. Turner, with Mr. Gibson. White or cream grounds.—First, Mr. Douglas, with Phidias. Second and third, Mr.

Turner, for Mrs. Knight. Fourth, Mr. Adams, for Slough Rival. Messrs. Douglas, Dean, and Cragg were the exhibitors of fancy varieties, and secured the prizes in that order.

The premier Show Auricula was, after a very careful selection on the part of the Judges, decided to be a fine example of Prince of Greens, in the collection shown by Mr. Wheelwright. The premier Alpine was Nellie Hibberd, a new seedling shown by Mr. J. Douglas.

Collections of Primulas came from Messrs. J. Douglas and R. Dean, who were placed first and second respectively, the former having freely flowered plants of *P. obconica*, *P. japonica*, and *P. verticillata*. Fancy Polyanthus from Messrs. Dean, Douglas, and Frettingham, Beeston, Notts, secured the exhibitors named the prizes in that order, Mr. Dean having two new varieties (*Charmer* and *Brightness*), for which certificates were awarded. Messrs. Douglas and Dean exhibited twelve hardy Primroses, and gained first and second honours, and two other varieties, Mr. and Mrs. Gladstone, were certificated. Mr. Dean had the best basket of Primroses, very bright and attractive varieties. Messrs. Douglas and Lambert were second and third. Gold-laced Polyanthus were not largely shown, the best specimens coming from Mr. J. Nicholson, Chingford; Mr. J. Weston, Mr. Dean, and Mr. A. J. Weston following.

Messrs. J. Laing & Sons, Forest Hill, were first with a magnificent group of flowering and fine-foliage plants, comprising Orchids, Tuberous Begonias, Palms, Ferns, &c. They were also first with a group of excellent Clivias in very fine varieties. Mr. W. Morle, Regent Street, and Mr. Nunn, gardener to J. Soames, Esq., Maze Hill, also showed well in the group classes. Mr. T. S. Ware, Tottenham, was first with a large collection of Daffodils, including the best varieties in cultivation and many novelties. Messrs. Barr & Son, King Street, Covent Garden, were second also with a fine collection, but they won premier honours for thirty-six bunches of Daffodils; Mr. C. W. Cowan, Valleyfield, Midlothian, taking first prize for eighteen bunches of Daffodils. *Dielytras* and *Spiræas* from Mr. Lambert were also noteworthy.

Miscellaneous exhibits comprised an admirable group of seedling Alpine and border Auriculas from Messrs. Sutton & Sons, Reading, who also had a group of dwarf compact handsome *Calceolarias*, remarkable for their good flowers and rich varied colours. A collection of well grown Clivias from Messrs. B. S. Williams & Son, Upper Holloway, comprised a number of the fine varieties for which the Victoria and Paradise Nurseries are famed. *Azaleas* and *Amaryllises* were well shown (extra prize). Mr. W. J. Chambers, Isleworth, had a group of the white *Viola Snowflake*, dwarf compact specimens bearing numerous large flowers. *Rhododendrons* from Messrs. Lane & Son, Berkhamstead, and *Tree Pæonies* from Mr. W. Gordon, Twickenham, formed effective groups. First-class certificates were awarded for the following plants:—

Auricula Magpie (Mr. J. Douglas).—One of the varieties raised by the Rev. F. D. Horner, belonging to the Show section. It is a white edge with black body colour, good solid paste and bright tube.

Auricula Nellie Hibberd (Mr. J. Douglas).—A seedling Alpine, which also secured an award as the premier in that section. It is a handsome variety, crimson maroon shaded, and gold centre. The flower is well formed.

Auricula Toujours Gai (Mr. J. Douglas).—An Alpine, with purplish crimson shaded flowers and a cream centre.

Auricula Lovebird (Mr. J. Douglas).—An Alpine variety, deep crimson, purple shaded; a peculiar tint and very distinct.

Polyanthus Charmer (Mr. R. Dean).—A beautiful variety, with bright crimson flowers and a yellow centre.

Polyanthus Brightness (Mr. R. Dean).—Remarkable for its rich magenta colour and clear gold centre; very fine.

Primrose Mr. Gladstone (Mr. R. Dean).—A capital variety, with deep crimson flowers and gold eye.

Primrose Mrs. Gladstone.—Very delicate creamy white, with yellow centre.

Primula cortusoides lilacina marginata (Mr. T. S. Ware).—Pale mauve and white, flowers very large, free.

Achimenes Rosy Queen (Messrs. Sutton & Sons).—An extremely distinct and handsome variety, with large flowers, the corolla broad, bright clear rose, white in the throat, evidently derived from a cross with some of the large flowered species of the family.

Calceolaria Cloth of Gold (Messrs. Sutton & Sons).—A large flowered pure yellow variety; very compact in habit, free and useful.

Auricula (Fancy) Bridesmaid (Messrs. Sutton & Sons).—An exceedingly delicate and beautiful variety, the flowers of good size and shape, the colour a soft French grey, with a faint rosy suffusion and a creamy centre.

Tuberous Begonia Princess of Wales (Messrs. J. Laing & Sons).—A fine single variety, a bright reddish salmon; extremely free, and capital habit.

Tuberous Begonia Gigantea (Messrs. J. Laing & Sons).—Single, bright rose, very large, the petals broad and round, admirable shape.

Tuberous Begonia Miss E. F. Cooper (Messrs. J. Laing & Sons).—Single, rosy salmon, a clear delicate tint; flowers of excellent shape and substance.

Clivia John Laing (Messrs. Laing & Sons).—A fine variety with deep orange red well-formed flowers in a dense umbel.

Clivia Bronze Queen (Messrs. Laing & Sons).—This appears to be somewhat more of a salmon than a bronze tint; it is very attractive in all its points.

Clivia Surprise (Messrs. B. S. Williams & Son).—An excellent variety, with large well formed flowers in a compact umbel, bright orange with a lighter centre.

Tree Pæony Lady Lotty (Mr. W. Gordon).—Flowers large, semi-double, white with deep crimson blotches at the base.

Viola Snowflake (Mr. W. J. Chambers).—Flowers large, pure white; very free, dwarf, compact, and well adapted for beds or culture in pots.

Narcissus Burbidgei Fulstaf, white, with small yellow corona; *Johnstoni Queen of Spain*, a pure yellow variety, very handsome; *incomparabilis Queen Sophia*, white, with a large undulated rich gold corona (figured in this Journal last week); and *Dorothy Wemyss*. All these were shown by Messrs. Barr & Son.

Wallflower Bedford Yellow (Mr. R. Dean).—Remarkable for its extremely dwarf habit, dark green foliage, and bright gold coloured flowers.

THE NEW MODEL LAWN MOWER.

THIS season's improvements in this easily worked lawn mower, by the Chadborn & Coldwell Manufacturing Company, are represented in the accompanying figures, and described as follows:—

"The journals of the 'Excelsior' and 'New Model' lawn mowers,

FIG. 54.

FIG. 55.

above 10 inches, are now furnished with the patent adjustable split bushing (fig. 54). This bushing is so arranged that all the wear of the cutter journals can be instantly taken up by the operator without taking it to the machine shop, which was generally necessary with the old-fashioned box bearings. The importance of these adjustable bushes is obvious when we consider that a lawn mower is simply a revolving shear, and in cutting with a pair of shears it is of the utmost importance that the shear blades be held closely together. The adjustable bushing is a simple mechanical device, which really compensates for the wear in the cutter journals, and thus holds the knives close to each other, and effectually prevents the grass from wedging in between them. This arrangement not only causes the mower to run much lighter, but also keeps the knives in better order, and saves one-half the trouble and expense in repairs. The 'New Model' and the 'Excelsior' are the only lawn mowers made in which these bushings are furnished.

"The section (fig. 55) shows the bushing in position, also the new handle clamp R, by which the handle can be set tight or loose as required. It also shows the patent adjusting screw, which adjusts the knives to each other. This is done by one screw on either side, and is much simpler than the old methods, whereby four screws are needed to insure steadiness. The patent positive pawl used in the 'New Model' mower is made of steel, has no spring, is noiseless in its operation, and is pronounced by competent engineers to be an excellent specimen of American mechanical skill."

The ease of movement of these machines is shown in the photograph (fig. 56) of a son of the London agent, Mr. T. Clarke, and the youngster, who is under ten years of age, appears to be doing his work well, and with the least possible exertion.

FIG. 56.—MASTER C. CLARKE.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—Present : Dr. M. T. Masters, in the chair; Mr. Morris, Rev. C. W. Dod, Mr. Godman, Mr. Michael, Dr. Müller, Mr. Pascoe, Dr. Scott, Mr. Wilson, and Rev. G. Henslow (Hon. Sec.).

Hybrid Narcissi.—Rev. G. H. Engleheart exhibited a collection of hybrids, amongst which was one called George Engleheart, a cross between *N. poeticus ornatus* and *Narcissus Tazetta*, Bazelman major. This was quite new, and received a botanical certificate. Another was between *N. poeticus* and a trumpet Daffodil, *Hudibras*; this had a remarkably large and flat crown. A third, between *P. poeticus ornatus* and Mary Anderson, had an orange streaked cup, both parents having an orange-bordered cup; the colour had become intensified. Mr. Engleheart observed that the anthers, being situated half-way between the points of the insertion of those of the two parents, was a characteristic feature of hybrids amongst *Narcissi*, and that no appreciable difference occurs on the hybrids raised when the parentage is reversed. He also remarked that Dean Herbert thought that *N. Tazetta* var. *Bazelman major* was barren with its pollen, as he could raise no plants from it. This was probably due to a too chilly climate. Mr. Henslow remarked that *N. Tazetta* is very abundant amongst the rocks in Malta, and has two forms, one with a short stout stem and many flowers, another with a long stem and fewer flowers.

Aristolochia Goldieana.—Mr. Morris commented upon the singular flower of this plant, which had blossomed at Kew. There had been a race between the flower-bud and the shoot-bud. The former was small, and proceeded out of the old wood. The flower-bud finally prevailed, and the shoot was thereby checked. It is an African species, differing from the South American in having ten stamens, &c. It is figured and described in the "Botanical Magazine," No. 5672.

Primrose, Variety.—Mr. Wilson exhibited a seedling from "Scott Wilson," of a deep blue-purple, with a red eye.

Plant Diseases.—Rev. C. Wolley Dod gave an interesting account of several diseases of plants in his garden, and commented on the difficulty of finding curative means, or of hearing of other suggestions than burning. He first alluded to a species of smut (*Ustilago*) on *Primula farinosa*, which appeared to be indigenous, as the plants were collected in Lancashire; and although it was grown with *P. denticulata*, the smut was confined to the former species. *Æcidium Ficaræ* had attacked his *Hellebores*. In this case a dryer soil was suggested as likely to prove effective in ridding the plants of the fungus. The "Lily spot," due to *Polyactis cana*, usually appearing late in summer, had been seen in April upon Tulips, and apparently the same species on Daffodils. It was suggested that a mixture of sulphate of copper and quicklime would prove effective, as in the case of Vines described below. *Puccinia Schrateri* had occurred on Daffodils from Portugal, and also upon the common double sorts.

Diseased Vines, treatment of, in France, with "Bouillie Bordelaise." Mr. Dod read the following communication:—"In the Médoc there are three applications of the treatment. (1) The first is towards the end of May, when the Vine has produced shoots about 30 centimetres long. At this period the flower of the Vine is not yet opened. (2) A second application is made at the end of June or the beginning of July. (3) A third, about the first half of August. The first application requires about 2 hectolitres of Bouillie per hectare; the other two, 2½ to 3 hectolitres per hectare. With regard to the preparation of the Bouillie, the following is the method employed:—For a 100 kilos. In one tub is put 50 kilos. of water and 3 kilos. of sulphate of copper; in another tub 50 kilos. of water and 2 of lime. The sulphate of copper having been dissolved and the lime well soaked the two liquids are then mixed. Cold water is used and slaked lime. Formerly small brooms made of Heather or Butcher's Broom were used to sprinkle the liquid on the Vines. Several varieties of syringe are now used. It was at first hoped that the Bouillie would destroy both the mildew and the *Oidium*. Up to the present time such has not been the case, and if the mildew is absolutely destroyed by this treatment the use of sublimed sulphur has to be continued against the *Oidium*."

Sulphate of Iron as a Remedy against the Potato Disease.—Rev. G. Henslow quoted the following passage from a report by the late Professor G. Gulia of Malta upon the Orange disease, but bearing on the question of the destruction of vegetable parasites:—"Having watered two Azaleas, three Begonias, an Orange, and several Rose bushes with a solution of sulphate of iron, in the proportion of six grains to one litre, these plants, far from sustaining any injury, seemed to gain intensity of colour to their chlorophyll, and their buds shot with greater rapidity and luxuriance. Towards the end of the past year Potatoes were attacked by *Phytophthora infestans* to such an extent as to impoverish and destroy the crop of the greater number of fields, especially in the eastern districts of the island. In a small field adjacent to others infected by the fungus the ground was sprinkled with the solution prior to the sowing of the Potatoes; some young plants sprang up, and the crop was so abundant as to astonish the cultivators of the neighbouring fields, who were seized with a longing to adopt the method in question. Not a single leaf of these plants bore the fatal fungus. This was certainly due to the sulphate of iron which had destroyed the spores buried in the soil, and rendered the plants so vigorous as to impede the growth of the pernicious fungus."

Colours of Flowers, Experiments on.—The following communication was received from Mr. Smee: "Some years ago, when experimenting with flowers and plants placed in a weak solution of silicate of soda, I noticed that the plants and flowers were affected by the solution according to their colour. The colours disappear in the following

order:—blue, lilac, red and brown, whilst yellow was the most persistent. Greens behaved according as blue or yellow predominated in its composition. The question has occurred to me whether the white varieties of flowers are not formed among plants in a similar order. We have an example in the blanching of the old flowers of *Francesia*. Then again in the poor varieties of *Vanda cœrulea*, the petals are almost white with very pale blue veining. In *Cattleya*, the colour of the petals and lip disappear, leaving the yellow throat and the pale pink tint (which so often spoils a white *Cattleya* from a florist's point of view), as the remains of the red tint in the mauve colour. Therefore, as yellow is so persistent, we cannot expect a *C. citrina* to appear amongst our white varieties. The white 'crispum' is due to the disappearance of the brown blotches, leaving only the yellow markings on the column; and in the case of the yellow 'triumphans,' which is a poor form of the ordinary type, the brown blotches are either absent or are in process of disappearance. The only pure white forms of Orchids are *C. cristata alba* and *D. Kingianum album*, sec. *Hæathi*."

Primrose with Foliaceous Corolla.—Mr. Douglas sent a plant with the corolla foliaceous; the calyx was normal. It is a not uncommon form.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced House*.—Alexander stands at the head of the very early Peaches, and ripens from the middle of April in a house to which fire heat is applied at the commencement of December. It is large and rich in colour, and the quality good. Waterloo ripens about the same time, is large and of good colour, but unfortunately a clingstone. Those are succeeded by Early Beatrice, which although a well coloured and good flavoured fruit, is rather small. Early Louise and Early Rivers are fine fruits, though pale in colour, and are particularly rich in flavour. Unfortunately they are liable to crack at the stone, which is to some extent lessened by fertilising the flowers with pollen from the small flowered varieties. Hale's Early, Early York (Rivers' variety), and Grosse Mignonne will form the connecting link between the very early varieties and such standard varieties as Royal George, Stirling Castle, a very fine form of Royal George, and Grosse Mignonne, which are several weeks later in ripening, there being six weeks between Alexander and Royal George. Hunt's Tawny and Lord Napier Nectarines form a good prelude to Elruge and Violette Hâtive, and a good succession may be secured in one house, the only change in the treatment being in not syringing such as have commenced ripening. Trees on which the fruit is ripening must have the foliage and fruit kept dry, or it will act injuriously upon the growth, and affect the maturity of the wood for future bearing. As the fruits of the other varieties will not be ripe for some time yet, the atmosphere must be kept moist by frequently sprinkling during the day, syringing the trees in the morning, and again when closing the house. The night temperature will be perfectly safe at 65° to 70°, but 5° less, though it will retard the ripening, will not tax the energies of the trees so much as the higher temperatures. Leaving the ventilators slightly open constantly at the upper part of the house will be an advantage. In the daytime 70° to 75° by artificial means, and 10° to 15° more with sun heat, will be suitable temperatures.

Trees Stoning.—Do not hurry trees undergoing this process, 60° to 65° at night is ample, and 70° to 75° by day, avoiding high night temperatures and sudden fluctuations by carefully attending to ventilation. A little ventilation left on at night will prevent the deposition of moisture on the foliage to any serious extent, increasing the ventilation when the sun shines upon the house in the morning, yet without lowering the temperature. Avoid fumigation if possible, it dries the foliage as well as the atmosphere, not infrequently crippling the leaves, when the fruit may from the check be seriously imperilled and fall. Early closing is an advantage, but it must not be done to the extent of undue excitement, nor continued until late, the temperature being allowed to fall with the declining sun. It is also advisable to allow a little extra latitude to the growth, but on no account allow foliage to be developed that must afterwards be removed in quantity.

Trees Swelling their Fruits.—There are two distinct periods during which the fruits swell most freely—viz., after setting until the commencement of the stoning process, and after stoning. The first is materially accelerated by a genial condition of the atmosphere, and the means employed to secure a good root action, which is best effected by a judicious and gradual regulation of the growth by the process of disbudding and in thinning the fruits. Overcrowding is a great evil, but large reductions of growth at one time as well as of fruit are not good. The more vigorous the tree the greater is the danger of the fruit being cast in stoning, and the evil is afterwards accelerated by severe disbudding. In the last swelling after stoning the shoots should be well tied down, so that the fruit may have the benefit of all the light possible, but a moderate extension of growth will materially assist the fruit in swelling, care being taken that the principal foliage and fruit be not interfered with. Supply water thoroughly to inside borders when necessary, and weakly trees should receive liquid manure.

CHERRY HOUSE.—When the stoning is completed the fruit will commence colouring. The temperature must not exceed 65° by artificial means, and 50° to 60° at night, with a little ventilation, increasing it at 70°, and not allowing the heat to rise above 75° without full ventilation, closing at 70°, subject to the leaving of a little air on constantly at the top of the house. From the commencement of the colouring of the fruit until the trees are cleared of the fruit the syringing must cease or the fruit will crack, but a good moisture should be maintained in the house by keeping the surface of the border moist, or if the trees are in pots damping the floors two or three times a day, avoiding, however, a stagnant atmosphere. Aphides must be kept under by fumigation; their presence for any length of time disfigures the fruit. See that the borders do not want water, and liquid manure should be liberally supplied to trees in pots.

FIGS.—*Earliest Forced Trees in Pots.*—The fruit will now be ripe or nearly so, hence the supply of water at the roots must be diminished, syringing being discontinued and a free circulation of warm dry air afforded, leaving the top ventilators open a little at night. Although less water is advised during the ripening of the fruit the soil must be kept moist, and a moderate moisture in the atmosphere secured by an occasional damping of available surfaces, but this will only be necessary in very bright weather. As soon as the first crop is gathered syringe the trees twice daily, renewing the top dressing, and watering at the roots with weak liquid manure. If the second crop of fruit be very abundant they must be thinned out so as not to overtax the trees for early forcing next season. It is only the very early varieties to which the syringing and thinning apply at present.

Early-forced Planted-out Trees.—The fruit will be in the last stages of swelling and will soon commence ripening. The border must be examined, and if necessary given a thorough supply of water or liquid manure. Cease syringing the trees when the fruit commences ripening, avoiding a superabundance of moisture about the house, having a little ventilation at the top of the sashes constantly and a free circulation until the fruit is all gathered. Do not gather the fruit until it is thoroughly ripe unless it has to be packed.

Succession Houses.—Frequent attention must be given to stopping the shoots at the fifth joint, and subsequently to one or two, but too many side shoots must not be encouraged, as the fruit and wood require light and air for maturation. Train extensions in their full length, thinning or removing strong growths so as to admit light and air to the fruit. Attend daily to syringing the trees, and supply water as necessary to maintain thorough moisture at the roots. Renew the mulching if necessary, and keep it moist so as to encourage the roots to and keep them near the surface.

KITCHEN GARDEN.

TOMATOES.—Cut the fruit off the early plants as soon as it indicates ripening, and let it mature on the shelf in the house. This will allow the later fruits to swell and ripen much sooner than if they were all left on until they were quite ripe, and the earlier the fruit can be secured now the better, especially for market purposes when the prices are high. Plants that are bearing heavily should have a thin surface dressing of soil and manure placed over the roots. They should also receive copious supplies of liquid manure, but do not overfeed any plants that have not commenced bearing. Restrict the plants to one or two main stems. They require attention in this way twice weekly when in active growth. The fruit does not form freely in a damp atmosphere. It is a great advantage to have very forward plants for the open air, and as they cannot be planted until the end of May backward plants should still be kept in a warm genial atmosphere. They should be in 6-inch pots, and if moved into a cool place by the middle of May, and planted out in a fortnight or three weeks afterwards, success may be expected.

ASPARAGUS.—Prevent the surface of the beds becoming a mass of weeds by hoeing or salting. Do not cut from roots that are under three years old. The very small heads that are not sufficiently strong for use may be allowed to grow, but all that can be used should be cut when from 6 inches to 10 inches in length. This may be done until the latter end of May. The heads may be cut level with the ground or a little below it, and care must be taken that those which are still invisible are not injured before they come above ground, as they sometimes are by the feet or knives of careless workmen. Seed may be sown now to produce new roots.

PEAS.—Those who grow their Peas without stakes will find them fail to yield so freely as those that have supports, and, if possible, they should all be staked. Where the ordinary wood stakes cannot be procured, wire netting 4 or 5 feet high, and with meshes 4 inches wide, may be used. If this is put up on each side of the row, and fixed to a stake here and there, it will be found to form an admirable support for the Peas. More seed of the main crop varieties should now be sown. These will furnish gatherings about the end of July, a time when the first flush of the supply is getting over, and when pods are often scarce and inferior. Many persons find well manured Celery-like trenches good for the production of succulent Peas during times of very hot dry weather.

SLUGS AND SNAILS.—As there are now many tender young seedling vegetables in the garden the above pests are very active and destructive, especially after rain and in humid weather. A sprinkling of fine fresh lime if thrown over the surface after dark when the slugs are feeding as often as necessary will be found effectual, and benefit the ground at the same time.

SALSAFY AND SCORZONERA.—These are generally sown and grown together, but the former is the more useful. They are apt to "bolt"

before gaining maturity if sown too early in the season, but this is not likely to occur by sowing at the present time. Break the soil up well, do not put any long littery manure into it, see that it is over 1 foot in depth, sow the seed thinly in drills 15 inches apart and 2 inches deep.

STERILE SEEDS.—There are more of these than we anticipated after such a good season as was experienced in 1889. Some of the Onions are particularly bad. A few sorts have proved a failure, while others from the same seed firm are as good as usual. When it is ascertained beyond all doubt that some kinds have failed the sooner new and good seed is obtained and sown the better, as the loss of a few weeks in sowing Onions will affect the weight of the crop materially. This also applies to Carrots, Parsnips, and all roots and bulbs requiring a long season to gain maturity.

LARGE LEEKS.—Those large Leeks seen at shows and elsewhere in the autumn are not the result of sowing seed in the usual way in the open, but the plants are raised and grown for a time under glass. They are hardened like tender bedding plants, and planted out in the open early in May. Many of them are now ready for planting in trenches similar to those required by Celery.

LARGE SPRING ONIONS.—The large spring Onions, many of which were shown in the autumn of 1889 of unusual size, are raised in the same way and planted out about the same time as the Leeks, but on level ground made very rich near the surface, and in the sunniest of positions.

MISCELLANEOUS.—Withdraw Vegetable Marrow and Ridge Cucumber plants from heat, and harden them to make them fit for planting in the open air shortly. Sow Radish seed in small quantity once a fortnight, and only raise Lettuce in small batches. Earth up early Potatoes, and sow more Round Spinach seed.

THE BEE-KEEPER.

NOTES ON BEES.

THE APIARY.

If the bees had a splendid beginning from the 1st to the 6th April it has been the opposite since. For nearly three weeks the gathering of honey and pollen has been almost entirely stopped, while the Plum and Gooseberry blossoms are nearly past. The latter do not look as if they will hold well, many being yellowed. Many bees have been lost, and weak hives have suffered more in this respect than strong ones, and hives where feeding has been delayed are now in a critical state.

The Sycamores are the succeeding honey yielders, and should the weather prevent the bees getting them there will be no alternative but to feed until the Clover and fine weather come; and if a honey harvest is expected it is imperative that they be fed, and that liberally. It is not the first time that bees have had to be fed the whole summer to tide them over another winter, so we need not despair nor neglect to perform all the work necessary to profitable bee keeping. The season is young yet, and although the first chance of honey gathering has been lost most hives are in excellent condition to secure honey in the second gathering should the weather permit. This will put them in the best of order for the Clover, only they must not be allowed to suffer from insufficient feeding.

YOUNG QUEENS.

These are the first and principal essentials to secure whatever the season may be, whether it be for the present or next year's work. When these are raised and fertilised early in the season it is a double advantage in more ways than one over those raised late in the season.

MAY SWARMS.

If the weather is favourable swarms in May will be the rule this year. In districts where the honey gathering ends with the middle of June, with no prospect of Lime or Heather honey, means should be taken to prevent swarming as much as possible; but when they do swarm in spite of all precautions join two together.

Where Heather abounds the opposite course may be pursued, and Nature may be allowed to take its course with advantage to the bee-keeper. Those who practise the above will in some years, from the extra material or hives in hand, find it greatly to his advantage to reduce his number by joining two or more together, taking the honeycombs that can be spared and joining the brood ones. By so building the hives are in the best possible condition for the Heather harvest, and with a young and fertile queen in a large hive the chances of swarming are reduced to a minimum and the profit raised to the maximum.

Details in many cases might be advisable, but the foregoing outline will enable any practical bee-keeper to understand what to do and how it should be done, and the pages are open for answering novices any query they may put, so as to enable them to perform the necessary work as well as the more advanced. Some of the more important manipulations will be described in future

issues. The most important point at present is not to allow bees to suffer by want of food.

THE USE OF FOUNDATION.

The proper and profitable use of foundation is to use the right sort, genuine native wax, having the natural worker cell with thin septum and high side walls, so that six sheets when laid flat upon each other measure an inch. This used in full sheets in the brood-nest is taken advantage of by queen and bees alike, and I have repeatedly seen eggs laid half an hour after the bees were hived, and in twenty-four hours after hiving all more or less drawn out without the slightest buckling or breakdown. It is the high side walls that give the proper strength, and insure straightness, and the thin midrib or septum, and firm native wax along with allowing the bees ample room to start with, that prevents breakdowns and twisting. A heavy midrib of soft wax has the opposite effect of strength.

Supers demand guides, and it is simply a question of quality how much should be employed. Foundation for sections should have the same kind of cell as that for brood, but should be as thin as possible with a medium side wall. Wax employed by the bees to build and seal honeycombs is slightly of a different nature than that employed in the body of the hive possessing a portion of more brittle and heavier substance than is to be found in wax extracted from brood combs. If the former could be preserved and wrought into foundation it would be more pleasant to eat honeycomb made from it than from wax of brood combs. But it cannot, it is far too brittle, and being heavier than the tougher portion their affinity appears to be gone when melted.

COVERING FOR HIVES.

"Will you kindly permit me, through your columns, to ask your correspondent, 'Lanarkshire Bee-keeper,' by what means the sacking or felt is attached to the Lanarkshire hive, and whether more than one thickness is required? What length and width should the alighting board and porch be for the above hive? Ought four 5-lb. supers to occupy the full length and width of the divisions? I shall be much obliged for the above desired information.—J. D. L., *Northumberland*."

For covering the body of my hives when no outside case is employed I wrap the sacking or woollen cloths so as to cover to the top of the body of the hive, the supers for obvious reasons having an independent covering, which laps over the body one. When the wrappings are made tight a patent pin at the bottom holds it firmly until the operator passes a card tightly round near the top. One, two, or three thicknesses or plies may be employed, depending much upon the thickness and quality of material at hand. The felt should be used the whole breadth (32 inches), and long enough to lap some inches over the wrapping, and is held close at the bottom by a brass nail with a head and nut passing through the felt an inch or so from the edge. The felt should overlap the floor at the back and the two sides, but clear of the doorway at the front.

A cord at the top, or another B bolt keeps it together. It is liable to drop; to prevent that nail a broadish strap of cloth to the upper edges, and tie firm, or fold over the surplus breadth, either prevents it dropping and closing the entrance against the bees. A hive so covered with the addition of dried grass on the top cannot be improved upon, and I consider hives uniformly and neatly covered need not be an eyesore in any garden. The alighting board must be the full width of the hive, 4½ inches broad, and attached to it by means of two staples and hooked wires to form a hinge. Another board 9 inches broad reaches to the ground at any angle required. If the alighting board is hinged to the hive with brass butts the hive becomes much handier to move about. Four supers should occupy the whole superficial top of hive, but if a protector is used then they should be made to allow it to slip over the supers easily. Caution.—Prevent any hard substance getting between the supers and protector, or there will be a difficulty in taking the latter off.

The moveable porch should not be less than 8 inches high in the clear, and 4 to 6, or even 8 inches wide, and extend the whole width of the hive; if broader than the first named it should be correspondingly higher. The main advantage of a porch is to prevent the bees being whisked from the alighting board by high winds, and there is nothing better than two broad haffets reaching to the ground, and as high as is convenient.—LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Ed. Pynaert Van Geert, Ghent, Belgium.—*General Catalogue of Plants, 1890.*

Ryder & Son, Sale, Manchester.—*List of Primulas and Begonias.*

Messrs. B. S. Williams & Son, Victoria and Paradise Nurseries, Upper Holloway.—*Catalogue of New Plants, 1890 (Illustrated).*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Continental Tradesmen (*Sundriesman*).—We have no list of the particular class of dealers to which you refer. Lists of continental nurserymen are published in the "Horticultural Directory."

Peculiar Auricula (*Somerset Ward*).—It is an example of fasciation, which, however, is more commonly seen in a combination of the flower stalks than in the corolla itself. Although there is apparently only one corolla much larger than usual, there are two series of stamens and two pistils. There are also double the usual number of calyx divisions.

Storing Fruit (*J. A.*).—Flour barrels are excellent for storing fruit in, and any other boxes or barrels that are perfectly sweet will answer, but the fruit will absorb any flavours good or bad that may linger in the boxes. See what Mr. Wright says on this subject on page 115 of his prize essay on fruit-growing, post free 1s. 3d. from this office.

Dahlias (*J. McC.*).—You will find the following good varieties—Cactus Dahlias: Juarez, scarlet; Empress of India, crimson; Constance, white; W. T. Abernethy, white edged with red; Yellow Juarez, and Cochineal, deep crimson. Single varieties: White Queen, Paragon, maroon, edged purple; Terra Cotta, bronzy yellow; Chilwell Beauty, yellow; Firefly, scarlet; and Mauve Queen.

Iron Stakes for Roses (*J. G.*).—Your letter was one post too late for being answered last week. We have seen iron stakes used for standard and pillar Roses for years without injury resulting, and we know of one large standard Rose that has been secured to an iron stake for twenty years. It is very desirable to have something as a pad between the stem and the stake. We have heard of iron stakes affecting Roses prejudicially, but no instances have come under our notice. They have been used for Dahlias in a garden for forty years with the greatest satisfaction.

French Salads (*H. R. W.*).—We have seen quite as good examples of salad vegetables grown in England as in France by persons who have rich soil and suitable appliances, such as frames and cloches for early produce, but all English cultivators do not devote the same attention to salad growing as do the generality of French gardeners, and, as a rule, the same care is not exercised in preparing salads in England as in France. It is entirely fanciful to suppose that because seeds are obtained direct from France the best produce will follow. If a French salad grower obtained seeds from a good source in England, he would raise just the kind of produce you admire in the French markets. Poor soil, and overcrowding plants when small, are the causes of many failures. Such a work as you name would not be a commercial success.

Mildew on Roses (*St. Julien*).—Syringe your Roses with a solution of sulphur and water, a 3-inch potful of the former to three gallons of the latter. The sulphur should be first mixed with a little water into a paste, and then the remainder added. If you syringe your Roses thoroughly this will destroy the mildew if you allow it to remain upon them three or four bright days and then wash it off. Cold draughts and dryness at the root will cause mildew, and nothing will keep the plants free for long if these important matters are not carefully attended to. Mr. Bardney is very careful about the admission of air to his plants, and recommends as a preventive syringing them every time syringing is needed with a solution of softsoap and water. The method of preparation is to boil about 4 lbs. of softsoap with a little water in a saucepan for twenty minutes; to this six gallons of water is added, and half a pint of the solution is placed in a large water pot full of water for syringing.

American Blight (*Idem*).—You will find methylated spirits effectual. It should be applied with a small gum brush. Very little is needed, and most of the spirit should be pressed out of the brush before the affected parts are touched with it. Petroleum diluted will answer the same purpose, but you will fail by one or two applications of anything to root out this pest. It may require constant attention over a considerable time. However carefully syringing may be done with any solution it is next to impossible to reach all the insects. When the trees

are leafless they may be painted with a mixture of clay, tar, softsoap, and petroleum.

Improving Fruit Trees (Young Hand).—You have not the slightest need to apologise for writing, and you can send us a letter at any time when you think it will "do you good." We think your efforts in improving the trees and garden generally most commendable, and you appear to have proceeded on sound lines. The bird difficulty is not easy of solution. It is a very serious one in some districts where the fruit bud destroyers are regarded as "pets" and protected. Birds are useful, but an excess in numbers over a given area injurious. It is so in respect to most things, and even an excess of "pets" does not add to the comforts of life. If you bring the intelligence with which you are endowed to bear on your work in improving trees and encountering difficulties, you will have as a reward in due time a fair and, we trust, a good measure of success. Towards the realisation of this you have our best wishes. Your other note cannot be attended to this week.

Journeyman's Work in Gardens (J. F.).—You ask "If it is usual for head gardeners to send their journeymen out of a night with a bulls-eye lamp and a bucket of soot to kill snails as late as half-past nine, and to expect them to go about during the summer evenings with a barrow of lime for the same purpose?" It is not usual in all gardens for journeymen to be employed as suggested, though we know of young men who are responsible for certain crops, who would and do very willingly apply soot and lime after dark when the slugs are out on their foraging expeditions, because one dressing then is more effectual than half a dozen in the daytime, when the depredators have had their feast, and are resting beyond reach of the caustic applications. In some gardens labourers are employed in such work, and paid by the hour for doing it, and that seems a fair and reasonable arrangement; but at the same time a young man seldom loses anything by showing his willingness to help in an emergency, and he does so the more cheerfully when the head gardener shares in the work, either actively or by his pleasant superintendence.

Wiring House for Roses—Pruning Marechal Niel (G. L. M.).—The wires may be a foot from the glass if there is sufficient head room. In low houses we have seen them 6 inches from the glass, and the Roses grew and flowered well; but we prefer more space for a free circulation of air between the growths and the glass. We cannot refer to the method of pruning which you say is advised in our issue of April 6th, because there was no issue of the *Journal of Horticulture* of that date this year. We were recently in a lean-to house 30 feet by 10 feet, the roof of which was covered with Marechal Niel, except 5 or 6 feet at one end. A hundred dozens of blooms had been cut, and sold at the rate of 4s. a dozen, and in all probability the long strong growths which produced them have since been cut down to the base of the rafters. That method, properly carried out, is the best we know for producing the greatest number of the finest blooms of this favourite Rose over a given extent of surface. Some persons we know have failed with it either because the plants were inherently weak, inadequately supported, or allowed to become infested with mildew or insects.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. —(G. H.).—1, *Staphylea colehica*; 2, *Deutzia gracilis*; 3, *Scilla peruviana*; 4, *Scilla nutans*. (W. R. O.).—1, *Sanguinaria canadensis*; 2, *Omphalodes verna*; 3, *Primula rosea*; 4, *Primula verticillata*; 5, *Primula obconica*.

COVENT GARDEN MARKET.—APRIL 30TH.

A LARGE consignment of Tasmanian Apples to hand in good condition, prices at first ruling high but settling down afterwards to fairer values. Hothouse goods in steady supply.

Bedding Plants in variety, in boxes and pots.

THE JOURNAL OF THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

THE issue of the first part of this journal in a quarterly form is a new departure, calculated to extend the usefulness of this Society, for the work, though less bulky as a quarterly than a half-yearly publication, has a wider and more general scope, which includes many minor details of agriculture, and short pithy articles under the distinctive heading of "Notes, Communications, and Reviews," the first of which by Mr. Charles Whitehead on "Fruit Farming for Profit" is really a review of Mr. J. Wright's prize essay on "Profitable Fruit Growing," of which the veteran Kentish "grower" evidently entertains a high opinion, for he says of it, "To those whose lot is not cast amid orchards and fruit plantations, who are ignorant it may be of the first principles of fruit culture, this work would be invaluable."

Of special articles Mr. Ernest Clarke, Secretary of the Society, has an interesting paper on "The Foundation of the Royal Agricultural Society," followed by the important contribution of Sir James Caird on "Fifty Years' Progress of British Agriculture," in which the chief features—not by the way always progressive—are portrayed with a masterly hand. The writer "marks time" in every change of our agriculture during the existence of the Society, and notably so when he says, "The collapse of prices which took place in 1885, falling as it did upon an agricultural class already impoverished, has greatly disheartened both landlords and tenants, and has seriously crippled their power to give employment to their labourers. Its effects are at the same time felt among the tradesmen in the country villages and towns, whose business is dependant on the spending power of the country squires and farmers. It is a remarkable fact, illustrative of the change of the agricultural

system, naturally brought about under the influence of foreign competition, that the home production and value of Wheat in England and Wales at the end of fifty years of the existence of the Society, which at the commencement was estimated by Mr. Pusey at 13,500,000 quarters, worth £31,000,000, will not in 1890 exceed one-half of that quantity, and be worth not more than one-third of it in value." He goes on to show the swift increase of the area of land under permanent pasture, of its probable further extension and limits, and to what extent British agriculture may be calculated to hold its own in the future. The paper abounds with matter of importance, which will furnish subjects for thought and discussion among agriculturists for some time to come.

An article by Mr. Henry Evershed on "The Early Fattening of Cattle and Sheep" has something of the tone of an historical sketch, touching points of progress in the more prominent breeds. He touches on the importance of careful selection, of dentition as a guide to determine the age of young animals, and gives useful examples of the practice of some of the best managers of live stock. Here he enters usefully into details of treatment, especially in regard to diet. The gist of the whole article is, Select and breed with judgment, rear the calf or lamb carefully, allow no falling-off in condition, but finish and sell the animal as quickly as possible, and it is bound to prove profitable. In proof of this, evidence is adduced that it costs no more to finish twenty well-bred young bullocks under skilful treatment than it does half that number of Irish steers that have been let down in condition.

Sir J. B. Lawes, in "The Food from Agricultural Crops," gives us another suggestive paper from which many a useful hint may be gathered. It dwells chiefly upon the sources of nitrogen, and it shows how, after a very wet winter and spring, the soil in which winter corn is growing may be low in nitrogen, and we take it that the practical application of this teaching is to apply a surface of nitrate of soda to such corn at once. An able article, too, is that in which Mr. William Carruthers gives the results of his observations on some English pastures, which, if taken apart from the Rye-grass controversy, is of considerable importance, for the observations embrace pastures in several counties. They have evidently been made with judgment and care; the deductions are sound, and he says well that, "In laying down land to pasture, as in sowing fields with Wheat or any other crop, we must try to surpass Nature. We must bring together the most nutritious perennial plants which will supply palatable food for stock as far as possible all the year round, and we must exclude weeds and worthless grasses which we have found too abundant in natural pastures. We must also consider the almost universal complaint of the deterioration if not failure of new pastures after the third or fourth year, and avoid short-lived grasses."

The number contains much other useful matter, and it certainly gives fair promise of a valuable and popular series. The price is now only 3s. 6d., and we strongly recommend owners of home farms to give a copy to their bailiffs as a wise investment in their own interests, for the teaching is sound, and the writers have evidently all given full recognition to the Society's motto, and have striven to combine practice with science.

WORK ON THE HOME FARM.

Since writing our last note we have seen some excellent crops of Winter Beans with a full plant as healthy and vigorous as heart could wish. The loss of plant appears to be confined very much to clay farms where a considerable area is usually devoted to this crop. Experience has shown that the loss of plant in spring on such land generally follows an exceptionally mild wet winter, which induces early growth and renders the plant liable to injury from late frosts. The harm is done close at the surface, where the temperature is always lowest, the cuticle being destroyed, which leads to the decay of the root and destruction of the plant. This year the harm was done by the short spell of very severe weather during the first week of March, when we had upwards of 20° of frost, and the minimum temperature of March 4th was the lowest recorded in that month for thirty years.

Pasture from which the stock was withdrawn last October is now

sufficiently forward for the dairy cows, affording an agreeable contrast to that of a neighbour who turned out cows and store beasts daily throughout winter, often only to stand about shivering in cold and wet, with the miserable result of now having a bare pasture, and what is even worse, four cases of abortion which the veterinary surgeon attributes to exposure. Abortion is often termed a mystery, but in this as in many other instances it is a result of mismanagement.

Among green crops sown this spring one of the most important was a few acres of Lucerne near the homestead, chiefly for horses, but also for the cows. This is one of our most useful and safe forage crops, altogether preferable to such a doubtful novelty as Prickly Comfrey, for once established it may be mown repeatedly every summer; it continues in full vigour for several years, is unaffected by drought, and only requires sowing in rows wide enough apart to admit of the free use of horse hoes to keep down weeds. Why it is not sown as extensively as Sainfoin, Clover, or mixed seeds, is a question we have never been able to answer to our satisfaction, for the value of the crop is so apparent, and all animals are so fond of it, that instead of being practically ignored as it now is, it ought to hold a leading position among such crops.

OUR LETTER BOX.

Gorse and Comfrey as Forage Crops (Long).—Cut, crushed, and mixed with chaff and other food, Gorse is a valuable addition to the dietary of both horses and cattle. It also has a special value as food for dairy cows in winter and spring, as it tends materially to improve both the quantity and quality of the milk. Here is its analysis:—

Water	72.0
Albuminoids (flesh formers)	3.2
Fats	1.1
Carbohydrates (heat producers)	8.2
Ash	8.0

The fibre may be taken as making up the numbers to 100, and to show the value of this analysis we may add that the per-centage of albuminoids in Oat straw is 3.5, or a mere fraction more than in Gorse. It thrives in poor thin soil, and yields from 7 to 10 tons per acre every year after it is well established in the soil. It should be sown at once in a fine seed bed in drills 9 inches apart, using about 25 lbs. of seed per acre. The young plant is not ready for use till the second winter, and it suffers from weeds, so that in land at all foul the drills should be sufficiently wide apart for a free use of the horse hoe between the rows, in which case much less seed will be required. When once established it may be mown just like any other forage crop, and it continues throwing up an annual growth of wonderful vigour in shallow soils, where hardly any other profitable crop can be grown. Prickly Comfrey, on the other hand, is a much overrated plant. We gave it a fair trial in deep alluvial soil, where it grew freely enough, but nothing would eat it freely, and the only way to get rid of it was to pass it through the chaff-cutter and mix enough other food with it to induce the stock to consume it. In this way it may be turned to account, but having regard to the fact that it is a gross feeder, requiring deep rich soil at the outset, and heavy dressings of manure subsequently, we came to the conclusion that it was unworthy of extensive culture, and we simply retained a small plot of it upon the home farm for a few years as a curiosity.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 20th.—Fine and mild, with occasional faint sunshine.
 21st.—Bright early; cloudy and hazy morning; frequent spots of rain all afternoon and evening.
 22nd.—Wet from 2 A.M. to 5 A.M.; dull and drizzly till noon, then bright sunshine and high wind, but slight showers between 3 and 4 P.M.; clear night.
 23rd.—Fine and frequently bright in the morning; alternate sunshine and showers in afternoon; wet night: solar halo 4 to 5 P.M.
 24th.—Dull and damp early; cloudy till 3.30, then a little sunshine, and rain in evening.
 25th.—Very wet from 7 A.M. to 1 P.M.; cloudy till 3.30, then frequent sunshine.
 26th.—Brilliant early, and fine and generally bright till 11.30, then overcast and dark; heavy rain from 0.30 to 2.30 P.M., then fair again.
 Range of temperature still rather small, temperature near the average, a wet week, grass frozen on 26th.—G. J. SIMONS.

WHATEVER may be said as to the relative qualities of coloured and uncoloured fruit, there cannot be two opinions as to which may be considered the most appreciated generally. Not merely are highly coloured fruits the most preferred, either for home dessert or exhibition purposes, but their greater value is even more strikingly apparent when they are consigned to the markets. As a matter of fact more importance is attached to high colour by Covent Garden salesmen than to any other quality, not even excepting great size, the fruit may possess. As a proof of this I have only to state that as late as July in the past year inquiries were made and tempting prices were offered in this and various other districts for highly coloured fruit, and that too when there was abundance, of Peaches especially, in the markets. Badly or only slightly coloured fruit, perfect in every other respect, would hardly fetch 6s. per dozen at that time, whereas highly coloured samples, no matter what the variety might be, were worth from 9s. to 12s. per dozen. There is no necessity to enlarge upon the greater attractiveness of richly coloured fruits on the dining table, while but few need to be told how much better chance they stand of winning a first prize at an exhibition than equally well grown or it may be much larger fruits. I am not prepared to assert that the most highly coloured fruits are the best in point of quality, but it is very certain they cannot be said to be coloured at the expense of flavour and lusciousness generally.

There being no disputing the truth of what I have just advanced, the question will or ought to arise, Why are highly coloured fruits comparatively scarce throughout the greater part of the season? All good gardeners are most anxious to colour their Grapes to the best of their ability, and why should they not be equally solicitous about Peaches and Nectarines? And echo answers, Why indeed? Probably, most probably I think, they are not so remiss in the matter as might at first sight appear, the failures to colour the fruit being more often due to misdirected efforts than to any want of zeal. Much depends upon the selection of varieties, some being naturally almost devoid of rich colours, others will not under any circumstances take much colour, while there are a few that under ordinarily good treatment are almost certain to be richly coloured. Noblesse and Princess of Wales are well known yellow Peaches, while the Alexandra Noblesse will only colour very slightly. Grosse Mignonne and its many synonyms, A. Bee, Barrington, and Walburton Admirable, are not often seen well coloured, while the three varieties most frequently seen in perfection are Crimson Galande, Bellegarde, and Royal George. Among the best known Nectarines the most difficult to colour satisfactorily are Victoria, Lord Napier, and Pitmaston Orange, Pine Apple being more often seen good, but no one ought to fail with either Elruge, and especially Stanwick Elruge, Hunts Tawny, and Downton. A grower may, however, have good healthy trees of the most surely coloured forms and yet fail to do justice to them. Sometimes this may be due to the art of colouring not being studied or the necessity for it recognised; but more often than not it may be attributed to being too late with what steps are taken to accomplish the desired end. After repeated experiments I have arrived at the conclusion that the colouring ought to commence before the stoning period, and that, therefore, the fruit must be well exposed to the light in advance rather than after either the

stoning or final swelling has taken place or has commenced respectively. Especially is this necessary in the case of the more green or badly colouring Nectarines, notably Victoria and Lord Napier, as these ought to have a good tinge of colour in them when no larger than small Walnuts; in fact it is my belief the only variety of Nectarine that will colour really well without early exposure is the Stanwick Elruge, the same remark applying to the Crimson Galande Peach.

With the view, then, of growing highly coloured Peaches and Nectarines, close attention must be paid from the outset to duly thinning first the buds, then the fruits when set, and also the disbudding, stopping and early removal of superfluous leaves, or any which unduly shade the reserved fruit. Only the best placed fruits, where there is any choice, ought to be left, these being on the upper side of the branches of trees covering either roofs or semicircular trellises, and which face outwards on wall trees. I annually remove thousands of the under or back buds on the trees in our heated houses, having no doubt about or difficulty in effecting a good set, but in a large unheated house no early removal of flower buds has been carried out since we once lost nearly the whole of the uppermost or most exposed flowers by a severe frost in March. In all cases directly it is seen abundance of fruit is set the thinning should be commenced and completed before the stoning process begins. This early completion of the thinning may appear a somewhat risky proceeding, and in any case to have no direct bearing upon the colouring process, but I beg to differ from such a thought expressed or otherwise. When far too many fruits are left on a tree in anticipation of a portion of them failing to stone or swell, this is simply a sure means of inviting the occurrence, whereas if the thinning has been done early and in a judicious manner few or no fruits will fall, and the trees will not have weakened themselves in their effort to perfect more fruit than they prove capable of doing. I do not positively assert that a moderately heavy crop of fruit is the most likely to be well coloured, but we invariably gather our handsomest fruits from the trees under glass which are in the most healthy state, and over-cropping has plenty to answer for without being saddled with yet another failure.

During April and May there are so many matters to attend to that few gardeners have much time to devote to the Peach and Nectarine trees, and this may be another reason why exposing the fruit is delayed longer than it ought to be. We find, however, that unless this important detail is attended to before the final swelling commences there is a likelihood of many fruits being scalded and much disfigured during the first hot day following upon their sudden exposure. The skins of Peaches and Nectarines, the latter especially so, if unduly shaded, are very tender, and therefore most susceptible of injury by scalding. They will not endure strong sunshine, and for a time at least after sudden exposure the glass over them should be temporarily and lightly shaded. A light shading is necessary in some houses to prevent the Pine Apple and Lord Napier Nectarines from being scarred, even though they have been fully exposed from the first, and is, therefore, doubly needed where this precaution has not been taken. As it happens, abundance of light rather than strong sunshine is required, both to harden the skins and develop colouring matter generally, and there is yet another element to be taken into consideration. As a rule, the fruits grown on open walls are the most richly coloured and tempting in appearance, although not equal in quality to those grown under glass. This justifies me in assuming that plenty of air has much to do with the colouring of fruit. It is a well-known fact that some kinds of Grapes, notably Black Hamburgs, will not colour properly in a heated close atmosphere, and judging from what that eminent novelist and pomologist Mr. R. D. Blackmore puts into the mouth of a prominent character in a most interesting book entitled "Christowel," he also is of opinion that wind is an important factor in the colouring of Apples and Pears.

Be this so or not, it is very certain house-grown Peaches and Nectarines ought to have plenty of light and air, as well as heat and moisture, each and every condition being about equally essential to success.—W. IGGULDEN.

HARDY FLOWER NOTES FROM SCOTLAND.

THE garden is at present brilliant with spring flowers, and the difficulty of selecting for notice becomes greater day by day, but a few notes and reflections may be seasonable and of interest to some.

The Aubrietias are very fine this season, and form splendid mounds of brilliant yet chaste colouring. Conspicuous among them is *A. Leichtlini*, which well deserves the encomiums it has received. The habit may not be quite so compact as that of *A. rosea*, but the colour is certainly better, and the two are welcome "breaks" from the other varieties. Could we only have a better white Aubrietia than *A. Antilibani*, which is too dingy, we would have a charm added to the spring garden which we would gladly take advantage of. The common *Arabis albida* is as yet the best white flower to associate with the Aubrietias for early bloom. Add to this *Saxifraga Wallacei* or *Camposi* for succession, and but little is required. The *Arabis* is more fleeting, and is now getting past its best, while the *Saxifrage* is giving us only a foretaste of the beauty it will exhibit in another week. Many other Mossy *Saxifrages* are now in flower or rapidly coming forward. That little gem *S. muscoides atropurpurea* is now very fine, and what was to me a new species named *S. globosa* was just coming into flower in a garden I saw a few days ago. The half opened flower of *S. globosa* would lead one to expect a large form of *muscoides atropurpurea*, but the flowers when open are a beautiful blush. Possibly they may pass off white, but I have not seen the plant at this stage. We may be losing something in our rage for "new things." The little *S. hypnoides* covering some stones, and hanging down to and encroaching on a gravel walk, was a picture of beauty a week or two ago with its beautiful dark green velvet-like mound of foliage, and now it is rapidly covering itself with its little flowers, which are far from being so pure as some, but are yet beautiful. The whole genus is an especial favourite of mine, but one fault in the pursuit of knowledge regarding these beautiful plants is the difficulty encountered in identifying species received without names.

Several *Fritillarias* are now in flower, and it is unfortunate that the most effective position for the display of their nodding flowers is so often denied them. They are seen at their best on rockwork at or near the level of the eye, but are too frequently planted in the ordinary border, where the want of brilliancy of colour, which characterises so many of the species, causes them to remain almost unnoticed, so nearly does this approach to the colour of the bare earth. Although not recommending or considering the advantage of growing them on rockwork, Justice, who published the second edition of his "Scots Gardener's Director" in 1759, and who seems to have been an enthusiastic cultivator of *Fritillarias*, might teach some of us in the nineteenth century a lesson in garden effects. He recommends planting Dog's-Tooth Violets as a groundwork, with *Fritillarias* in rows between the *Erythroniums*, "for," as he says, "the *Fritillarias* flowering much about the same season with the *Dens canis*, the former is naked in its stalk, and carries no Leaves near the Ground, whilst the low Leaves of the *Dens canis* adorn and embellish the Surface of the Beds, and the flowers of the Variety of *Fritillarias* seem to proceed from the beautiful variegated Leaves of the *Dens canis*." Justice gives a long list of *Fritillarias*, all of which he says are Dutch seedlings; but some appear to be the same as some given by Philip Miller as species. The subject is a tempting one, the genus being very interesting, although it is not everyone who can appreciate the beauty of the flowers. For instance, *F. pyrenaica* is externally sombre and rather unattractive, but turn up the bell-shaped flower and it is impossible to withhold an expression of admiration at the colour and markings of the interior; and *F. meleagris alba* is one of the daintiest of our spring flowers, and a fine clump of this exquisite variety which I saw the other day would evoke admiration from many who care little for such types of flowers.

Numbers of the *Narcissi* are now in flower, but the recent report of the Daffodil Conference renders comment almost superfluous. I was much disappointed in a hurried visit to the Edinburgh Botanic Garden on April 18th to see so few of the Daffodils; indeed, comparatively few hardy plants were in flower, and one was struck with the lateness of the season in Edinburgh compared to what it is with us on the Solway. A few species of *Muscari* were in bloom, and *M. armeniacum*, *M. atlanticum*, and *M. Szovitzianum* were among the best, the last apparently superior to the others. A very dark-coloured flower was named *Botryanthus*

atlanticus. This bears a considerable resemblance to *Muscari racemosus*, but is larger, and has more of a purple tinge on the flowers. In the same gardens *Anemone pulsatilla* showed how well this fine native species is adapted for the rock garden.

One of the neatest of the Iberises, *I. petræa*, was coming into flower. A few days later I had the pleasure of examining one of the best collections of alpine plants in the south of Scotland, and one of the finest plants in flower was a *Thlaspi*, *T. alpestre*. It appears to be by far the finest of the genus, and is of close dwarf habit with flowers of a pure white. It is, I believe, a scarce plant, and I am of opinion that it is not at present in commerce. The little *Erysimum pulchellum* is doing well this season, and its clear yellow blooms have shorter stems than usual, which is a decided advantage, as some seasons the stalks are too long for the size of the flowers. This *Erysimum* does best with me planted on a ledge of rockwork, and allowed to hang over. In winter, if in an exposed situation, it seems to suffer much from the bitter north winds. We have had an early season all along, and although the cold east winds have checked things, no great harm has been done. To-night (April 29th) a gentle rain is falling, which will revive plants beginning to suffer, so that we may expect in a day or two to have additional charms added to the display of the season, which has been the most favourable for our light soil that we have experienced for some years.—S. ARNOTT.

THE CULTURE OF LETTUCES.

ALTHOUGH the Lettuce is by no means a difficult plant to grow, the production of large solid heads of crisp leaves is not so general in gardens as it should be. This is to be accounted for in many ways, the main cause being sowing the seeds too thickly and the consequent crowding of the plants before they are pricked out in nursery beds, and finally transplanted in the positions in which they are to develop. This error is too common, not only in raising Lettuce plants, but also Cabbages, Cauliflowers, and all plants of the Brassica family, and I may add plants of every description indoors as well as out. It is an evil that no judicious after treatment will altogether remove, though good culture will do much towards securing fairly satisfactory results from plants so neglected.

Lettuces—other points being properly attended to—will succeed in any fairly good soil. Early and late planting should be made in a warm and somewhat dry situation, this being preferable to a cool moist one. But these conditions are highly favourable to the production of Lettuces of the best quality during the summer and early autumn months. Liberal dressings of well decayed manure should be dug into the ground a good spit deep some time before setting the plants in it, although very satisfactory crops are yearly obtained by planting the ground the same day it is dug. However, should the manure dug into the ground be of a rank description, it is certainly prudent to defer planting for a few days until the rankness has escaped. Plants raised in autumn, wintered in cool pits and warm dry borders, and planted out with good roots in February and March in warm situations in rows 1 foot asunder and the same distance between the plants in the rows, will soon be fit to cut, and in many places will supplement the supplies of salading hitherto obtained from plants growing under glass. Lettuces raised in heat in January and afterwards gradually hardened before being pricked off in warm corners out of doors will succeed the autumn-raised plants transplanted in February and March, the supply being continued by plantings made from seed sown at the foot of a south wall or fence towards the end of February or early in March, and again at the end of the latter month, the middle of April, and at intervals of three weeks up to the middle or end of August.

Many excellent varieties of Lettuces have been introduced into commerce in recent years; so many, indeed, as to perplex not a few gardeners and amateurs making out seed orders. However, the following may be mentioned as being among the best to grow—viz., Sutton's Mammoth White (Cos), Paris Green (Cos), Carter's Longstander (Cabbage), Sutton's Favourite (Cabbage), and Grand Admiral (Cabbage) are everything that could be desired for summer and early autumn use. Sowings of Carter's Giant Bath (Cos), Kingsholm (Cos), and Sutton's Marvel should be made about the end of the first or second week in June, and again a month later. Plants from these sowings will be ready for use in September, October, November, and December. The last sowing to raise plants for use in heated and cool pits during the months of January, February, and March, and in sheltered sunny situations out of doors in April, May, and the early part of June, should, as already stated, be made from the middle to the 25th of August, according as the locality is late or early. This sowing should consist of such well-tested varieties as Improved Black-seeded.

Bath (Cos), Hicks' Hardy White (Cos), and Hammersmith Hardy Green (Cabbage).

PRICKING OUT AND TRANSPLANTING.—If these operations are not carried out in due time the plants become crowded in the seed and nursery beds, and poor results are obtained in consequence. Therefore, if the object be to produce examples of good cultivation in the shape of large close heads of tender Lettuces, the young plants when a couple of inches high and before they touch should be pricked out in a border having a south or west aspect in rows about 4 inches apart and at the same distance in the rows, making the soil moderately firm about the roots, and if no rain fall at the time supply water through a rose-watering pot to settle the soil about the roots. If the ground be ready by the time the young plants are fit for pricking out they may be placed in rows 12 inches asunder and at the same distance between the plants in the rows, giving water to settle the soil about the roots, as already advised. Before planting the ground should be trodden and surface-dressed with soot before raking it level, as the Lettuces will do better by being planted in a fairly firm ground, and the dusting of soot will save them from the attacks of the grub, which in some soils is very destructive, eating through the stems of the plants underneath the surface of the soil. However, very good Lettuces may and are every year grown on Celery ridges during the interval of making the trenches and earthing-up the Celery plants in summer. But if plants thus grown are not pretty well supplied with water at the roots during a spell of dry weather thin loose heads of tough leaves will be the result. Where there is plenty of ground the largest, most solid, and crisp heads of Lettuce are secured by sowing the seed very thinly in drills about 1 inch deep and 12 inches apart, the ground having been previously dug, trodden, and raked level, afterwards closing the soil in drills with the feet, treading and raking it level in the same direction as the drills. In due time the plants should be thinned, first to 6 inches apart, and later on to 12 inches in the rows. Thus grown, and being afterwards attended to in the way of giving water at the roots when necessary, the plants never experience the slightest check.

In transplanting Lettuces, which had been previously pricked out as indicated above, they should be taken up and planted with a garden trowel with good balls of soil adhering to their roots, letting them into the ground the same depth as they were before, and making the soil firm about the roots. In making early plantings of Lettuces level the soil well up about the stems of the plants, so as to prevent the lodgment of water with the result of encircling the plants occasionally with ice. But on the other hand, in making plantations during the summer a slight depression should be left round the collars of the individual plants for the reception of water. Successional plantings, like the sowings, should be made every three or four weeks to the middle of August. The plants raised from seed sown during the latter month should in due time be dibbled out, those in slightly heated pits at 6 inches every way from plant to plant, drawing every other plant for early use before they touch, allowing 3 inches between the plants in cool pits and in warm and somewhat dry borders out of doors. The plants in cool pits and out of doors must be protected from frost by shutters and fern and similar material. Slugs being very troublesome to Lettuce plants so grown they should be sought and destroyed, subsequently laying occasionally a mixture of fresh soot and lime between the plants and the wall, fence, or edging as a means of keeping them off.

Plants raised from seed sown in June and July will be ready for cutting in the late autumn and early winter months, and good breadths should be planted for this purpose. The July raised plants for lifting with good balls of earth, and carefully transplanting 3 or 4 inches asunder in a cool pit or frame, placed on a south border, before they are injured by frost, say the end of October. The plants may be placed the same depth in the ground as they were before, giving water to settle the soil about the roots. This should be poured through the pipe of the watering can round the stems and roots, so as not to wet the leaves. These plants should have abundance of air in the absence of frost and heavy rains, and always bear in mind that the great enemy to be guarded against in the preservation of Lettuces during the winter is damp.

The only attention which the several plantations made during the spring and summer months from the interval of planting to cutting is to keep the plants well supplied with water at the roots during dry weather until they have taken well to the soil, and to keep them free from weeds by passing the Dutch hoe between the rows a few times, an operation that will at the same time promote growth in the plants.

BLANCHING THE HEADS.—The object of the cultivator should be to get as great a portion of the leaves of the individual heads of Lettuce as white and tender as possible, therefore recourse should be to tying up the leaves, but not too tightly, with bands of matting

when the heads are nearly full grown. The leaves of the Cos Lettuce being, as a rule, self-folding they do not require tying, although by doing so the process of blanching is more completely effected. The Cabbage Lettuces generally require being tied up; this should be done when the leaves are dry. One band of matting tied within a couple of inches of the top of the heads is quite sufficient for each Lettuce.

As wood pigeons, pheasants, and sparrows are in some districts very partial to young Lettuces their movements should be watched, and if necessary a piece of garden netting be placed over the plants until they have become well established and the attention of the feathered tribe diverted.—H. W. WARD, *Longford Castle, Salisbury.*

VARIATION IN PLANTS.

(Continued from page 356.)

As regards marvellous floral forms and adaptations, no family of plants equals the Orchids, but it is impossible to deal with their structural peculiarities in reference to cross fertilisation in these notes. Charles Darwin's book on the subject contains the greatest number of facts observed or recorded, and elsewhere I have endeavoured to give a few ideas on the subject. One peculiarity stands out prominently in the Orchids as a means of attraction, and that is the labellum or lip, a singularly modified structure, totally distinct from anything in other flowers, but with just a distant resemblance to the lower portion of the corollas in the "two-lipped" flowers previously noted. It is in this organ that the majority of the modifications occur that render Orchids so exceedingly interesting, and the rich colouring often in bold streaks and bands render them equally beautiful. The lip serves as a lure to insects; it even serves as a bait, and in some cases as a trap for the creatures it compels to perform the service of hybridisers. The strange resemblances to other insects in certain cases, the powerful odours, and in some cases even the unusual colours are all directed to the same purpose.

But it is not in the corolla alone that means are provided to ensure cross-fertilisation; the stamens in numerous instances show quite as evidently their structural adaptation for a certain purpose. In the two-lipped flowers, the *Salvias*, &c., they are often strangely curved; in the upper hooded portion of the corolla the separated lobes of the anthers are curiously hinged connecting portions, so that an insect when entering the lower part of the flower touches one end and forces the other down on its back, the pollen being then carried to another flower.

The stamens are sometimes of different lengths, as in the *Primulas*, giving rise to the phenomenon of dimorphism or trimorphism, when two or three forms respectively are present. Long stamens and a short style (thrum-eyed flowers of florists); short stamens and a long style (the pin-eyed flowers of florists); and when the stamens and the style are about the same length. Combinations between these forms give different results, but the intercrossing of two extremes give the best. Occasionally, also, the anthers are in a mature state before the pistil of the same flower, and the reverse occurs in some instances, this being really a means to prevent self-fertilisation, and consequently indirectly to encourage crossing, at least with other plants of the same if not with distinct species.

There are still other modes of promoting cross-fertilisation in a state of nature—namely, where the pollen is produced very freely, is light and powdery, and consequently is easily distributed by the wind. The *Willows* and many of our deciduous trees are examples of this, and in most cases the flowers are individually inconspicuous, but compensate to some extent by being in clusters or dense drooping catkins. Having now briefly reviewed the chief points in regard to natural cross-fertilisation, we may turn our attention for a few minutes to the same process as conducted by us under artificial conditions.

ARTIFICIAL CROSS-FERTILISATION.

What has been already said will indicate that in some of the modes described, or by a combination of them, plant variability is induced in nature on an extensive scale and continuously, and when we reflect upon the ages during which this has been in operation it is not surprising that plant forms are extremely diverse, and distinct floral structures equally numerous. A little attention to what has been effected artificially, even within the present century, is sufficient to show how great the range of variation is and how much can be done by the skilled horticulturist to multiply the beautiful and useful flowers and plants in our gardens. What has been done in the past should act as a guide to the future, and it is work in which almost every amateur and gardener can engage. The subject is very far from being exhausted, and some of the

greatest future triumphs of horticulture must be looked for in the results of methodical hybridising. It is, however, essential to start with an object, work on a system, be patient and persevering, and results will ultimately come perhaps of a surprising character. Amongst both ornamental plants, vegetables and fruits there is still ample scope for experiments, and if these give nothing else they at least afford considerable interest.

In undertaking artificial hybridising or crossing the condition of the plants should be carefully studied. It by no means follows that apparently strong plants are really the best as parents, either as seed or pollen parents. It often happens that excessive vigour in plants is antagonistic to the production of good seed or strong and improved seedlings. The vegetative and reproductive system of plants seem to be in a measure opposed to each other after a certain stage is passed. Plants of moderate growth are invariably the best seed producers, and usually afford the best pollen also. This is one point that should always be kept in mind in commencing experiments in hybridising, and never attempt by the application of stimulating manures to induce excessive growth under the mistaken impression that an advantage will be gained. If anything is required beyond that afforded by the soil in which the plant is growing it should be given after the fruit or seed pod is swelling. At the same time weakly plants should never be chosen for the purpose, and in the case of rare Orchids it is dangerous to allow a small or improperly developed plant to bear seed, as the common result is the death of the parent. It requires some judgment to select plants in a fitting condition, but it is always safe to select the sturdy, the well matured, and the hardier plants for seed parents.

The relative effects of seed and pollen parents I have treated at some length in a paper on the subject read at a meeting of the Horticultural Club recently, and which appeared in the *Journal of Horticulture*, page 234. It is only necessary to recapitulate the chief points of interest here. One is that in some cases, especially in the Orchids, a complete fusion of characters takes place in nearly every instance where cross-fertilisation has been effected between species.

Another is that in some plants, *Primula sinensis* and its varieties being cited as examples, the seed parent gives the majority of the characters inherited by the progeny. As a general rule the seed plant gives more of the habit and foliage, and the pollen the floral colouring, but there are many exceptions to this in different families of plants.

To produce a definite result close interbreeding sometimes becomes necessary, but simply to induce variation and secure as many distinct forms as possible it is better to cross plants as distinct in characters as possible, and grown under different conditions of soil and surroundings. Remember also what has been noted with regard to diverse lengths of stamens and the different periods at which pollen and stigma mature. All these matters have a direct bearing on the success or failure of experiments in hybridising. It is strange also, but it is nevertheless a fact, that where variability is greatest in particular species of plants, the pollen grains are usually most diverse in form, and the examination of pollen under a microscope of moderate power will often in this way indicate whether experiments are likely to prove satisfactory or not.

Partial fertilisation, when only some of the seedlings seem to have been affected in their characters, and sterility when the seedlings resulting from a cross fail to produce seeds, are examples of imperfect pollen action, or are due to some constitutional differences that we cannot ascertain. The greater vigour of some hybrids as compared with their parents is chiefly due to the sterility, and as a corrective to this less liberal treatment sometimes has a beneficial effect.

SELECTION.

In connection with crossing and seed-raising of all kinds, however, it is imperative that strict attention be given to selection, and it is in this that the judgment of the skilful hybridiser becomes most useful. It applies equally to the selection of parent plants and to the selection of seedlings for preservation. An accurate knowledge must be possessed of the plants under treatment; a quick eye and good power of observation detecting any special character that it is desirable to secure. Wherever large numbers of seedlings of any kind are raised the keen selector can often do nearly as much as the hybridiser on a smaller scale. Seed-sowing and rigid selection, leaving the fertilisation to the bees and other insects, have yielded remarkable results in many classes of hardy plants.

I must conclude these imperfect references to a great subject, and I can only hope they may prove suggestive. Patient perseverance and close observation are useful qualities to all men, and

whether we be students of the vegetable world, experimentalists, or workers, these qualities are indispensable to secure a measure of success.—LEWIS CASTLE.

AN EXHIBITION OF ORCHIDS.

ORCHIDS have had a long period of popularity, but never at any time in their history have they had so many admirers as now, and though some celebrated collections have been dispersed, others rapidly becoming equally famous are being formed, and the number of cultivators is still advancing. Ample evidence is afforded on all sides that Orchids are not only the favourites of fashion and curiosities for the student, but they include in their ranks plants of exceptional garden value wherever beautiful flowers are prized and floral decoration is required of a distinct character. They are in fact both beautiful and useful, returning a rich harvest to cultivators of all grades who give them the moderate attention and care needed to ensure a fair measure of success.

Mr. William Bull of Chelsea may claim a considerable share in the extended popularity of Orchids in recent years, for his annual exhibition at the King's Road Nursery has attracted large numbers of distinguished visitors, who have had their love and knowledge of the plants materially increased by what they have seen there displayed. Beyond this, however, many have probably for the first time there formed an adequate idea of the diverse charms possessed by Orchids, and when once the enthusiasm of an amateur is well awakened it is not readily restrained. The display Mr. Bull provides must certainly afford a surprise to any visitor who is not very familiar with the plants, and even those who are well acquainted with Orchids too rarely see them arranged so tastefully. It does not seem to be generally regarded that Orchids lend themselves most readily to artistic grouping, and attractive as a house or group of *Odontoglossums* or *Cattleyas* alone may be to a specialist, the uninitiated require an effect in which the diversity of form and colours is more strongly marked.

Recognising the innate adaptability of Orchids for grouping with Ferns, Palms, and similar graceful foliage plants Mr. Bull has availed himself to the fullest extent of their qualities, and has produced this year one of the most pleasing exhibitions he has yet held. This was opened on May-day, and will be continued for the next two months, sufficient proof of what a lengthened period Orchids may be made to cover, though this only represents the months when they can be obtained in greatest variety; for with a good collection of plants flowers can be had every day in the year. The house in the Chelsea nursery is span roof, with banks at each side and in the centre, and each end being fitted with mirrors produces the pleasing illusion of an indefinite extension, a prolonged vista of floral beauty. To enumerate all the Orchids shown would necessitate the publication of a formidable list of names that would after all convey a very imperfect idea of the effect provided. The most brilliant and richest shades of colour are harmonised or strikingly contrasted, and soft delicate tints are employed with equal judgment. Majestic *Cattleyas*, delicate *Odontoglossums*, and the popular *Cypripediums* are represented in their best forms, and contribute largely to the show. Specimen plants of *Cymbidium Lowianum*, handsome *Dendrobiums* in many species and varieties, *Masdevallias* both beautiful and peculiar, *Oncidium*s in their wealth of golden flowers, and scores of others that cannot be named now assist in making an Orchid exhibition that conveys a faithful idea of the family it represents.

ORCHIDS AT BERLIN.

In the recent International Exhibition at Berlin the display of garden architecture is said to have constituted the chief feature, but amongst plants Orchids were largely represented, chiefly from continental growers. Messrs. F. Sander & Co., St. Albans, were the only exhibitors from England, and contributed a fine group of over thirty specimen *Cymbidium Lowianum* bearing 2000 flowers; 200 plants of *Odontoglossum vexillarium* were also shown, with a specimen of *Oncidium ampliatus majus* bearing 5000 flowers and buds, and a *Dendrobium Brymerianum* 3 feet in diameter with 200 flowers. Besides other awards Messrs. Sander & Co. secured the only two honorary gold medals offered. Some large specimens of *Clerodendron Balfourianum* were exhibited by Mr. John Fox,

gardener to Count Henckel Von Donnersmarck, Upper Silesia, which attracted much attention from the English visitors. The plants were over 6 feet high, 3 feet in diameter, and were loaded with flowers.

MEGASEAS.

IN gardens where diversity and general picturesque beauty is sought Megaseas or Giant Rockfoils should always hold a prominent position, since we have few plants so distinctly beautiful for the greater part of the year, and at the same time so well suited to a variety of uses. We sometimes find really handsome established tufts of the commoner species, such as *M. cordifolia* and *M. crassifolia*, but it is only in isolated cases, and I only know of a solitary instance where they are grown extensively, and where also they are put to elaborate use, with such excellent results year by year. That solitary instance is in the charming spring gardens at Belvoir, and there it is one of the grandest hardy plants one could ever wish to behold, the species so extensively employed being *M. ligulata*, one of the best of the whole group; and if the exceptional luxuriance of this plant could be produced under ordinary circumstances, there is no doubt that it would soon become famous. The gardens of Belvoir Castle are, however, wonderfully favourable for the growth of these and many other hardy plants, for although I have grown this species by the hundred, I have never been able to obtain the noble foliage and the giant spikes of flowers which it produces in the gardens referred to above. Nearly or quite 2 feet high, with only ordinary care in somewhat stiff soil, and a sheltered spot, it is annually a charming picture of rosy white flowers in spring, while its foliage, carrying tints of bronzy hue in summer and autumn, renders it a welcome addition for association with other plants of more sombre hue.

From a cultural standpoint these Megaseas require a deep rich soil, rather stiff than otherwise, and which is all the better for the plants when fairly moist throughout the year; then in a position sheltered from cold and cutting winds, *M. ligulata* is a truly noble plant. One thing, however, has surprised me from time to time, and it is the extreme variability to be found in their adaptability to soils and positions. For example, *M. ligulata* in warm well drained light soil loses every vestige of foliage annually, but this is always retained in sheltered positions. I have side by side in the open ground that above named, also *M. crassifolia*, *M. cordifolia*, and *M. cordifolia purpurea*; the three latter are evergreen, and the last, notwithstanding that it has been propagated rather hard, outstrips all the rest in vigorous constitution, perfect hardiness in all winters, endures drought with impunity, and produces grand spikes of its pendulous bell-shaped reddish purple annually nearly or quite 2 feet high. But while this does so remarkably well in drier soils, I incline to the belief that it would be even more massive and luxuriant in a stiffer moister soil, and whether in flower or not the red bronzy shaded are always pleasing and effective. It is of garden origin and only of recent introduction. The type species *M. cordifolia* is a native of Siberia: *M. crassifolia* is also very distinct and attractive, forming close tufts of erect reddish leaves and spikes of rosy red flowers. Then there are *M. purpurascens* somewhat resembling the last named in growth, having deep purple flowers. A native of the Himalayas.

There are others again, the hardiness of which is by no means certain, and which must receive frame protection in winter, or, better still, if they could be accorded positions in the cool conservatory, planted out. Those requiring protection are *M. ciliata*, a handsome plant almost deciduous in winter, and producing hairy leaves, and white and rose flowers in spring time. On a level with this as to hardiness stands *M. Stracheyi*, an Himalayan species, of which also there is a white variety, the flowers of the type being pinkish externally, and is now in flower (February 27th). Another nearly allied kind is *M. Milesi*, also somewhat tender and inclined to deciduous. This last has rose and white flowers, and being somewhat dwarfer than the rest should be grown in pots. These deciduous, or semi-deciduous kinds—which, by the way, behave in a greater or less degree according to the circumstances under which they are grown, are, so far as the individual flowers are concerned, exceedingly handsome, and well deserving a place in all gardens where good hardy plants receive the attention they deserve. The more robust species are specially suited for the large rockery in bold masses, so placed that their stout leathery leaves may clothe the sides of projecting ledges of the rock.

Those named above, while including the leading species and varieties as generally known to cultivators, by no means exhaust the list of these valuable spring flowers, for already the hybridist has been at work, and his patience and perseverance rewarded by a rich and varied series of these plants; and although I am not as yet able to speak of their merits from personal observation, I have

reason to believe they include some very decided improvement in both colour and size of truss, colours too we do not possess in the older kinds. For these new and improved forms we are indebted to Mr. Thos. Smith of Newry, who no doubt will continue to improve this charming group. Happily, too, Mr. Smith is to be congratulated upon his choice of the parents of these hybrids—viz., *M. cordifolia* and *M. purpurascens*, both being of perfect hardiness and of vigorous constitution generally, a fact which may tend to render their offspring invaluable to the future generations of the gardening community.—J. H. E.

IRIS SINDJARENSIS.

AN addition to the early flowering Irises of dwarf habit attracted some attention at a recent meeting of the Royal Horticultural Society,

FIG. 57.—IRIS SINDJARENSIS.

when the Floral Committee granted Messrs. Barr & Son an award of merit for the plant. The flowers are of moderate size, and though less showy than the favourite early *Iris reticulata*, the delicate lavender blue tint is very pleasing. A most distinct character is afforded by the leaves, which are broad, closely set on the stem, recurving, and of a glaucous tint. The moderate size of the plant adapts it for culture in pots, and out of doors it would need a somewhat warm and sheltered situation to ensure its success.

CYPERUS DISTANS.

THE plant known in the market by this name is the most useful of all the *Cyperus*, and for various decorative purposes is surpassed by few plants. It is suitable either for the table, group-

ing, or any other form of decoration, while in the conservatory it is light, graceful and effective when associated with flowering plants. It rarely exceeds 18 inches in height, and plants in 5-inch pots will carry from four to eight of their spreading spikelets. It will last in presentable condition in rooms for two months provided the plants have not been pushed forward in brisk heat and are taken into the rooms as soon as the flowers show. In a light position the flowers even will there continue to come forward up to a certain stage.

Plants can be raised by division and seed, the latter being decidedly the quickest method, and better specimens are obtained than by division. I have never seen seeds offered for sale, though they are produced freely. The plants for seed bearing should be placed in a light sunny position in the greenhouse or outside during the summer; early in the year in an intermediate temperature. Directly the seeds are observed to fall the spikelet should be cut, and the others as they become ready. If they are sown at once disappointment will follow, for they are certain to decay. They must be thoroughly dried on a shelf or in the sun where they will ripen. After they reach this stage they may be sown, or can be stored away until spring. The seeds are small, brown and hard, and are two or three weeks in germinating. They can be sown with the husks attached, as these soon decay in the soil—when sown in this manner they are a little longer before the seedlings appear. The seed may be sown in pots or pans in fine soil and should be lightly covered. A good watering is necessary, and the soil must be kept moist, as the seeds being very hard they will otherwise lie for a long time before they commence growing. The pans may be placed in any warm moist atmosphere where the temperature is about 60°. Place them in the greenhouse or any position under glass, but the warmer the house the greater their progress in their early stages. The present is a good time for sowing seed, and the plants so raised will be in condition for decorative purposes from the end of November until the close of March. To have plants for decoration all the year sowings should be made now, again in May and during September.

When the plants are large enough they can be pricked off 2 inches apart into boxes containing a compost of fine loam and leaf mould in equal proportions, with a liberal addition of sand. For a fortnight afterwards they may remain in the temperature in which they have been raised, and should then be removed to a temperature 5° to 10° lower. In this position they will grow sturdily, and can remain until they are becoming crowded, when they may be placed singly into 60's (3-inch pots). A pit where the temperature is about 50° will be suitable if they are near the glass and standing on a moisture-holding base. The pit or house selected for them must be kept close until they have commenced fresh root activity, then air may be gradually admitted and increased daily when the weather is fine, free ventilation being necessary to keep them sturdy. By the time they fill these pots with roots artificial heat will be no longer needed, and the plants will have commenced to push up growth from the base. They should not be allowed to remain in the small pots long enough to become unduly crowded with roots, or they will be checked and fail to make satisfactory progress.

When ready place them into 5-inch pots, one "crock" at the base being ample. This time the soil may consist of two parts loam to one of leaf mould, one-seventh of decayed manure, and sufficient sand to render the whole porous. Press the soil firmly into the pots, and stand the plants in cold frames. In potting be careful not to break their foliage. Keep them close again for about a fortnight, and then gradually harden to cool airy treatment, closing the frames only at night. When they are once well established and growing freely they will be better than in the frames, but not before the end of June. Stand them on a bed of ashes, and be careful not to crowd them.

During August those that are needed for throwing up early should be selected from amongst the others, and will comprise the strongest and best plants. These should be placed in frames or in the greenhouse, where the ventilators can be closed at night, or partially so, to bring them on a little faster than those outside. No attempt, however, must be made to hurry them. In the following months, when the nights begin to be cold, the whole of the plants should be returned to frames where they can have protection at night when the temperature falls low. By the middle of October place them where they can be protected from frost. It is a good plan to sort them at this stage, placing them in different positions where the temperature during cold nights will range from 50° to 40°. Keep some in a temperature intermediate between the two. The object is to bring them forward gradually. If they are kept close the foliage is drawn weakly and breaks and falls about, while the spikelets that are thrown up are weak and poor in comparison with those allowed to grow and develop steadily from the first to the last. It is much better to keep them advancing slowly

than to hurry them and then try to retard them. If they are removed direct from heat to a cool house, their appearance will soon be destroyed by the foliage becoming spotted. The same takes place when they are placed in rooms from brisk heat; in fact, plants that have been hurried are next to useless for such positions.

Plants that have done duty and faded need not be thrown out, although this is the best plan, as they are so easily raised from seed. They can be trimmed, leaving all the foliage that is good, cutting the spikes away, and if placed in heat they will soon throw up again from the base. They will do so twice during the next season, but if kept in the same pots the spikelets will be weaker each time, and the foliage will be defective at the base. If they are retained when growth is observed issuing from the base they should be transferred into a size larger pot.

All that is necessary to say about the watering is that from the time the seed is sown the soil should be kept moist. The syringe may be freely used through their various stages, especially during the summer, because they are liable to attacks of red spider. If they are liberally watered and freely syringed this pest will give no trouble. When they are housed avoid placing them on a dry stage. All the feeding necessary is soot water in a clear state.—NORTHERNER.

THE BRITISH FRUIT GROWERS' ASSOCIATION.

THE Executive Committee of the above Association held a meeting in the Horticultural Club room, Hotel Windsor, on May 1st, T. Francis Rivers, Esq., in the chair. A number of members having been elected, the Hon. Secretary announced that Mr. Shirley Hibberd had consented to give a paper on the Origin of the Cultivated Strawberry at the June meeting. The proposed report on the Present Condition and Prospects of Fruit Culture was discussed at some length, and letters were read approving of the scheme. The Duke of Bedford sent a cheque for £25, and Earl Fortescue wrote as follows:—"I heartily wish you success in your work. I have long been of opinion that fruit culture may be largely extended in Great Britain and Ireland with advantage to the owners and occupiers of land and to the general public. Your Association has been rendering a real public service both by directing public attention to fruit culture for profit in this country, and by helping to dispel the erroneous idea too freely circulated respecting the enormous returns obtainable from a small capital employed in fruit cultivation. Your report truly observes that much harm has been done by ill-informed advisers, for fruit-growing cannot be made to pay a fair profit without practical knowledge of the work, starting with a carefully considered scheme, and sound judgment in carrying it out." A sub-committee was appointed to prepare a scheme to deal with the matter.

Mr. L. Castle submitted a note upon Paris green as an insecticide for special application to fruit trees, and described some experiments. The strongest mixture of this poisonous substance appeared to have no direct effect upon caterpillars, and it is only when it is lodged on the surface of the leaf and consumed by them that it becomes destructive. It had little or no effect upon the leaves as tried, and except when the mixture is not properly stirred there seems little danger in this respect. Experiments were also tried upon plants in pots to ascertain if any ill effect was produced by the Paris green passing through the soil to the roots; but the plants were quite uninjured, and being insoluble it is not taken up by the roots. It was mentioned that Miss Ormerod had kindly sent much information upon the matter, including her recent Report upon Injurious Insects. A large fruit grower also wrote as follows:—"We have a plentiful crop of caterpillars; we are, however, vigorously attacking them with Paris green, London purple, and quassia. We can hardly determine yet which will answer best, but the quassia appears to be quickest in its action, as it kills by contact, but with the other two you have to wait until they have consumed the poison."

CLASSIFICATION OF PICOTEES.

(Continued from page 364.)

MR. DODWELL TO MR. HORNER.

I AM greatly obliged by your most interesting letter of the 6th; especially for the permission you gave me of using it in the interests of our common brotherhood, and as I think none of your words should be lost, I propose to ask the editors to give them to the public, with the few remarks I hope may follow. I am gratified to note your acceptance of the proposed recasting of the Picotee section by marginal breadth, and I humbly trust I may truthfully aver I hold with you in its entirety the same floricultural faith. We stand one and indivisible on the same immutable law, so ably expounded by Mr. Jeans, and, happily, no longer a virtually buried book. You do me only justice in assuming I have no fear of the clap-trap of our critics. I would bend neither to the raging "of the heathen," nor to the sometime vain imaginings of our own "people." We differ, I proudly believe, upon no cardinal point. If we seem to diverge it is not upon principle, but upon questions of expedient practice, and even upon these questions I believe wherever we could bring them to practical test we shall be found in substantial agreement. Fifty years ago, before the growers of the north and of the south had a practical knowledge of each other, there was endless controversy upon the asserted difference of the flowers and the estimates of

florists in the respective districts. Well, the trial exhibitions of 1850 dissipated the illusion. Come then to our next meeting of August 5th, and I think the difficulties you anticipate in a "compôte" of colours would be found to be of small relative account; less by far at least than those existing in the present system, and which threaten indefinite extension. What justification can be found for laws which shut out from class showing a bizarre-edged Picotee? Form a class, possibly you may say. But this cannot be relied upon to remedy the evil. It extends a system already practically unmanageable for the effective presentation of an exhibition to the outside public; of only initial value to the florist himself; and very unequal in its incidence of competition. Let me not be thought to undervalue the single bloom. All floral knowledge and floral enjoyment must begin with it, and my estimate of its importance may be inferred when I say that at the earliest time I could make occasion—the exhibitions of the Midland Horticultural Society at Derby in the forties—I gave a prize for the best Carnation, and similarly for the best Picotee, selected from the whole exhibition, and it was at my instance the prizes for the premier Carnation and the premier Picotee became part of the schedule of the National. But in the multiplication of the classes I have noted great evil. Of the seeming difference in our views of the self and fancy classes I need scarcely speak. Of course we recognise the fact that both self and fancy occupy relatively a lower place than the bizarre and flake and Picotee. But I feel sure we shall equally agree the life of the Carnation cannot be fully illustrated without their recognition. And though, for all the higher enjoyment of the florists, the self and the fancy stand on the lower level, yet for some purposes, mainly those of import to the outside public, they have a very definite and important use. And this brings me to consider the question, What should be our attitude to the general public? Of course we give no regard to the caprices or excesses of mere fashion. They come and go, and are not. But I think with our good friend Hibberd, as expressed at our luncheon table, "Florists have an important duty to see that the public have the best in their several classes," therefore we lose no dignity if, for the nonce, we step down from our higher level to consider these lesser things, and as we are firm believers in the importance of comparison, these lesser things fitly occupy a place upon our exhibition tables. I have no thought of restricting the "legitimate" preferences of taste. Let the judge, if he thinks well, prefer his purple, his pink, his rose, or his red; well defined and well understood intrinsic merits being equal, his choice may well come in. But I do not anticipate practical difficulty in this. We find no difficulty in determining the premier flower from the whole exhibition, whether red, or rose, or purple, and I should be surprised to find any difficulty in deciding the merit respectively of a broad-edged purple, or rose, or red. On the other hand, an extension of the classes is, in the case of the "Union" at least, impossible. We haven't space. But if we had, I should be as stiffly opposed to such a solution of the difficulty. We now have eight divisions of hues or tints of colours. Last year we had six only. But it is said in the rose, or salmon, or scarlet-edge Mrs. Sharp is distinct from Mrs. Payne, from Edith D'Ombraire or Royal Visit, so a separate class is set up. The distinctiveness is unquestionable, but if distinctiveness of hue is to govern, what reason can prevent the separating into classes of the imperial purple of Amy Robsart and the soft lilac-purple of Mrs. Chancellor? And so for the marone-reds and the cheery-reds? Where would it end? And if three sub-divisions be sufficient respectively for bizarres and flakes, why should not a similar number suffice for the Picotee? This is no new subject to me. It has filled many an hour of thought in many a year of my life, and I embodied, generally speaking, its outcome in the note attached to the yellow-ground special prizess, "the judges are instructed to award these prizes to the *best and most effective flowers*." That instruction was the best I knew how to give. What could call more alike upon exhibitors and judges to make a wise and intelligent selection? And I desire, above all things, at all times to stimulate and be stimulated to the exercise of intelligence. I know no better way whereby I can adequately express my sense of the great favour and sympathy which has been given me in these my later days. Hoping, dear Mr. Horner, that you will be with us at our next meeting, and that there may be no gap in our circle of friends, with every kindly wish, I am, faithfully yours,—E. S. DODWELL.

P.S.—There is yet one other point—the question of £ s. d. Extension of classes means, of course, extension of prizes. Who shall provide the means? This is a subject which ought to be borne in mind, and, above all, we should be careful that the strong should not be given an advantage over the weak. I do not think you have given full weight to this point, nor to the point that florists are bound to present their exhibitions effectively to the public. Again and again in my experience we have been overwhelmed with the number of single blooms, and the litter and confusion incident to their production. To put exhibitors upon an equality, it should be one man one flower in each class. As regards means, I think we have gone to the utmost limit of necessity, and if instead of very narrow I had unlimited means, I should not willingly offer more. Proposing to send our correspondence to the gardening papers, I return herewith your own note, so that if you desire to add thereto you may have the means. When read, will you kindly return to me with my letter also, for I am really unable to copy it?—E. S. D.

MR. HORNER TO MR. DODWELL.

MANY thanks for the generous advantage of seeing your reply to my paper before publishing it. I do not know that I have much fresh to say,

except that wherein we may differ, it will not be in any unkindly way. You have had but one lifelong floral attachment, and I have many; and I do not, therefore, seek to pit my acquaintance with the Picotee against your mature and concentrated intimacy with it. I quite agree with you in your desire to cheer up the smaller grower, though I would hardly put it "as against the larger." We should encourage the one, and not discourage the other. It would be a pity that the small grower should be educated and scheduled to look upon the big grower as his natural enemy; or that the big grower should be ruled down and outclassed into feeling that he has no friends, and may be stamped on. The large grower, who with a large collection has also a largeness of care, anxiety, and expense, naturally looks to reaping as he has sown, in a larger recognition and reward than the smaller grower can reasonably expect with his lesser outlay of time and labour. In collections, or "pan" showing, the small grower is abundantly fortified. He may sally into the big man's lines by showing upwards into any class above his mark for which he can produce the flowers; while the big man may not show down by crossing the small man's frontier. But in single bloom classes, perfectly open ground, both small and great men meet together, generally without fear, certainly without favour. I do not see how you can handicap the large grower here without being unfair to him. Handicap both, and let neither show, in any class for single blooms, more than his best two flowers. That would do away with the merciless imposition on the judges, and the great absorption of space that must come of exhibitors pushing all their spare flowers into the singles because "they may win a shilling." But however you put it, the larger grower must have more power of choice, and in any arrangement this will tell, and I submit, ought to. If you have, in single blooms of Picotees, the flowers classed solely by depth of edge; one huge mixed class of heavies, the same of mediums, and the like of lights, here will the large grower come down strongly, with no restriction as to edge colour, so long as the depth of edge is there. If however, you maintain, in heavy, light, and medium edges, the well-established colour divisions, it may be that the big man shall here and there find himself spent or weak, and the small man bowl him over. I think the general effect of the single bloom classes, as now displayed, is very beautiful in the play of purple, red, and rose shades in those respective classes, while the powers of variation are seen at a glance in close comparison, which could hardly be in a motley crowd of all edges. Judging mixed edges in collections or divisions by depth of edge, and selecting the winners, is scarcely, I think, analogous to the task of finding the premier flower of a whole exhibition. The premier lies within narrow bounds. It cannot decently be outside the winning stands, or be 'ow the first prize flower in single-bloom classes. It is not likely to shine, the so e jewel in some rejected stand. Not alike easy, it seems to me, would be the filling of a long graduated prize list by assortment from materials mingled in all their mixed multitudes of edge colours. "There is no trust like trial;" but so far as I dare prophesy before I know, I think it would be more workable to keep the established classes by colour of edge, with sections in each for heavy, light, and medium, than to merge all colours upon chance of a new one breaking out, or because in the rose-edged some are rose scarlet and some salmon rose. I think our attitude towards the general public (as florists, in the peculiar sense in which we are peculiar!) is to show a florist flower in—and only in—its highest florist types. I think that we have no need to exhibit our mistakes, and say, like Beau Brummel's valet, when met returning from his master's dressing-room with an armful of crumpled cravats over his arm, "These are some of our failures!" The "life" of the Carnation, Auricula, Tulip—any florist flower in other than its florist forms—is surely a little beyond the range of our florist societies, which exist for the one definite aim of developing the flower in what are known as its florist types. I like a thing true to name, and a florist society is for the improvement of florist flowers as such. I cordially agree with you in agreeing with our friend Hibberd's remark that "Florists have an important duty to see that the public have the best in their several classes." But not out of them! Scarcely, to have to admit to a stranger of "the public" who may admire a run Carnation, or a nondescript prettiness in "fancies;"—Ah, yes! but that is not relatively a flower of a high standard in this scale of beauty. This is rather the "doing" our duty in the shady sense of getting out of it. Again, as to your comparison between the three classes of bizarre and flake Carnations, and the six of edged Picotees—with the suggestion why there should not be only three of each—I think the edge in colour and depth marks off the Picotee as distinctly as the stripes distinguish the Carnation; and that "to lump" the edge colours in Picotees would be analogous to lumping the Carnation colours into simply bizarres and flakes. It would be the easier perhaps, for the eye that sees dimly the difference between the crimson and the pink and purple bizarre, but it would not interpret the flower fully. So if we had Picotees classed only by depth of edge, the florist would miss all the delicate distinctiveness to which he is accustomed, and feel the calculation too rough and ready. Well! you must not take me for an autocrat on the Carnation or any flower. I only give you my opinion freely as you ask it. You may say of me playfully, "Ah! rather thin of petals on the Picotee question!" As playfully let me gently whisper, "Don't burst your pod!"—F. D. HORNER.

MR. DODWELL TO MR. HORNER.

I WILL add a few words only in notice of your letter of the 26th. You have done, and admirably done, that I asked for when I invited comments germane to my proposition of March 3rd. There is, I think, a little misunderstanding as to my feeling for the smaller as contrasted

with the larger grower. Certainly, I desire in nothing to handicap the larger for the benefit of the smaller; I seek, as throughout our exhibitions, to establish the nearest practical approach to equality by compelling the exhibitor to select, not contribute, in gross. Your suggestions to limit the number the exhibitor may produce in each class—which had previously reached me from more than one quarter, and which, I think, should be adopted—goes a long way towards meeting the difficulty, and will, I think, be most beneficial in practice. As regards the colours you do not touch upon the extension of the classes already adopted by the National, or quite sympathise with me possibly in my estimate of the effect such extensions may have. Practically I do not think a difficulty would be found to attend a competition of mixed colours. But if it be strongly urged the competition should not be of all colours and hues of colours let us at least try to find some solid ground for division, and separate only by primary colours, say of red and its hues, rose-pink, salmon, salmon-pink, and salmon-scarlet; purple and its hues to lilac. This would give us two divisions, including every colour at present developed in the white ground Picotee, and all, I think, likely to be developed. Be that as it may, it would give us a sure starting point at once, which the present system does not. I regret our divergence of views as to the selfs and fancies. But I cannot consent to look upon these sections as our “failures.” Interpreting our laws in the strictest possible sense, I hold they are well within our lines, so I think to exclude would be a sin of the gravest magnitude. Granting we are specialists, and our shows should be special, could we illustrate the life of the Carnation without these sections? Could I, because I thought there was more variety, more brilliance, more power in the bizarre, be justified in rejecting the less gifted self or the motley, whilst these latter for certain purposes of grouping or decorative effect beyond dispute excel the former? Personally of course I might, and no man, whatever he might think of my caprice, could rightly impose his law upon me. But in my character as chief servant to the Carnation and Picotee Union, what then? We have four hundred supporters at this time—to be five hundred surely before the year is out. Fifty of our friends come into line with you and I. Seven times fifty admire the Carnation, and seek its use from a slightly different standpoint. Can we ignore their requirements? Ah, no. Because we are virtuous we are not to forbid the innocent “cakes and ale”—veritable enjoyments to friends with tastes and requirements slightly varying from ours. Again repeating my hope you will be with us on August 5th, and cordially reciprocating all your kindly thought.—E. S. DODWELL.

EVENTS OF THE WEEK.—The Crystal Palace summer Show will be held on Saturday, May 10th; the Royal Horticultural Society's Fruit, Floral, and Orchid Committees will meet on Tuesday, May 13th, at the Drill Hall, James Street, Westminster; the usual monthly Dinner and Conversation of the Horticultural Club will also take place on Tuesday, at 6 P.M., in the Hotel Windsor. The subject for discussion will be “Common Sense and Common Non-sense in the Naming of Plants,” to be opened by Mr. Shirley Hibberd. The Royal Botanic Society's first summer Show of the year will be held on Wednesday, May 14th, in the Regent's Park Gardens.

— **THE WEATHER IN THE SOUTH** has been seasonable. The rain that has fallen on several days has proved most acceptable in hastening the growth of Peas and other vegetables. Gooseberries are swelling rapidly, and some of the earliest are already in the market.

— **THE WEATHER IN THE NORTH.**—April 28th–5th May. On the morning of the 28th ult. $1\frac{1}{2}^{\circ}$ of frost was registered. Since then the temperature day and night has been high, only three times under 40° ; last night's min., 49° . With few dull intervals the days have been bright and warm, coldish easterly winds making some of the evenings unpleasant. Vegetation has made a great advance during the week, and the country looks beautiful. Promise of abundant Hawthorn blossom in contrast to last year.—E. D.

— **NEW ZEALAND INTERNATIONAL EXHIBITION, 1890.**—The following first class awards have been made to Messrs. Sutton & Sons, Reading, at the above Exhibition:—Agricultural products, models of vegetables from Nature; models of agricultural roots from Nature, and a collective exhibit, special first class awards in this class being also adjudged to Messrs. Hurst & Sons, London, and Messrs. Arthur Yates and Co., Manchester.

— **THE SHROPSHIRE HORTICULTURAL SOCIETY.**—The annual great Exhibition of this Society will take place in the Quarry Grounds, Shrewsbury in August next, when about £400 is offered in prizes. From the balance-sheet of last year we extract the following items:—Receipts—Subscriptions, £416 16s. 6d.; taken at gates, £1206 17s.; tickets sold by Messrs. Admitt and Naunton, Hon. Secs., £525; from other sources, £179 7s. 6d.; the total income of the Society for the year, £2480. Enormous expenses attend the outdoor entertainments, which, in conjunction with the splendid display of plants and flowers, and fruit and vegetables especially, bring the visitors from far as well as the surrounding districts.

— **CLIMBING NIPHETOS ROSE.**—Will any rosarians oblige by giving their experience of the growth of the Rose sent out as Climbing Niphetos?—M.

— **GARDENING APPOINTMENT.**—Mr. George Maycock, for the last three years general foreman at St. Anne's Gardens, Clontarf, Dublin, has been engaged as gardener to E. J. Walker, Esq., Lead-works House, Chester.

— **CHANGE OF ADDRESS.**—Mr. G. Shrewsbury has removed from 122, Moorgate Street, E.C., to larger and more convenient premises at 36, Grays Inn Road (Holborn end), W.C., where all communications should now be addressed.

— **CATERPILLARS AND PARIS GREEN.**—I am much interested in this subject, and am making inquiries amongst Kent fruit growers, about which I hope to report you shortly, but the east winds a fortnight ago killed hereabout (Gravesend) thousands of juvenile caterpillars.—J. R. S. C.

— **THE** past month here has been noted for the small amount of RAINFALL, total amount for the whole month only being 0.77, greatest amount in twenty-four hours on the 16th being 0.20, minimum amount in twenty-four hours on the 7th being 0.03, being the driest month since the spring of 1888. Amount registered during April, 1889, being 2.16; much in excess of past month. The month began with very sharp frost, and nearly every night more or less frost has been registered.—E. WALLIS, *The Gardens, Hamels Park, Buntingford, Herts.*

— **HINTS ON VEGETABLE AND FRUIT FARMING.**—Under the above title Mr. Charles Whitehead has compressed much information in a manual of forty-two well printed pages. The matter originally appeared in the Journal of the Royal Agricultural Society, and the Council of the Society have decided to republish it in the present cheap and handy form. It is revised so as to bring the facts and statistics to a late date. Most kinds of useful vegetables and hardy fruits are concisely treated, though many details of culture are of necessity omitted, as are some crops usually grown in market gardens; and it is a little singular that the most profitable of all is overlooked—Mushrooms. On the whole it may be described as a useful epitome of the culture of the crops that are included in its pages. The manual is published by Mr. John Murray, Albemarle Street, London.

— **DEATH OF MR. JAMES CHEETHAM.**—The death of this old florist took place quite recently at Roehdale at an advanced age, and after a long floricultural career. James Cheetham's name will long be associated with Lancashire Hero Auricula, although he was not the raiser of it. It appeared first in 1846, raised by old Robin Lancashire, and in all probability originally named Lancashire's Hero. When first shown at Roehdale in 1846 it was placed second to a flower inferior to it in character, Grimes' Privateer. The Rev. F. D. Horner, in one of his pleasant papers on the Auricula, records that old Robin had then eight or ten plants of his magnificent grey, and in his great grief that it should be placed second to Privateer, hastily sold all for a trifling amount. Then repenting, he offered a great deal more to get them back, but could not have them. From their first purchaser they passed to Mr. James Cheetham, by whom it was eventually put into commerce. “But it is truly Lancashire's Hero, and no name but that of Robin Lancashire should be associated with this flower.” Like many other light-mealed grey edges it has the power of blooming in a green edged form, and that generally occurs either on a truss from a young plant, or one formed very early on an old one. At the recent Exhibition of Auriculas at the Royal Aquarium, Hero was well shown in its green edged character, but whether grey or green, it is always a striking and valuable flower. Latterly James Cheetham cultivated Tulips, Auriculas, and a few other florists' flowers, and I think I am correct in stating that for a time he had charge of the fine collection in the possession of Mr. C. M. Royds of Roehdale.—R. D.

— **DEATH OF MR. JAMES FLOOD.**—Many will learn with surprise that Mr. James Flood of London died suddenly on Sunday last, aged fifty-three. He had for many years been a frequent attendant at horticultural shows and meetings in the metropolis, with some of the principal in the provinces, and had a wide circle of friends. He was for a considerable time engaged in the Royal Botanic Society's Gardens, Regent's Park, as assistant to Mr. R. Marnock.

— **MESSRS. JAMES CARTER & Co.** suggest that the following record of QUICK VEGETATION may be of general interest:—"On April 17th last was sown seed of Cactus Dahlia Juarezii, in three days nearly every seed appeared to have grown, and the plants were well through the ground; they were ready to be, and were, pricked off on April 28th, and yesterday (May 5th) were upwards of 2 inches high."

— **ROYAL NATIONAL TULIP SOCIETY.**—The usual meeting of the growers and exhibitors of the Tulip was held in Manchester on the 30th of May, and a comparison of the different reports as to the progress and promise of the Tulip beds led to the annual Exhibition being fixed for Wednesday, May 28th, to take place as usual in the Botanical Gardens, Manchester, on the last day of the great Whitsun Show. At present Tulips promise to be early. The Rev. F. D. Horner reports that they are very early with him, both out of doors and in the Tulip house, and writing on the 2nd of May he states:—"I have a dozen or two blooms standing open to-day. At this rate of speed my blooms will not last for the National, or later than the third week in May." It will be seen from the above that the fixture is the fourth week in May. The exhibitors at the National Show have been thinned by the death of Mr. Alderman Daniel Woolley of Stockport, on Saturday evening last, the cause of death being pneumonia. He was a seedsman and druggist in the Market Place, and had strong floricultural tastes, but made the Tulip his specialty; and when the season suited his flowers he was generally successful with them. He will be much missed in the Tulip Shows round Stockport.

— **OUTDOOR MUSHROOM CULTURE.**—A striking example of how easy it is to grow Mushrooms out of doors is now to be seen in Mr. James Hodges' garden at King's Heath, Birmingham. Two beds, each about 12 feet long and 6 feet wide, were made up out of doors in January last, the manure prepared in the usual way, and when made firm were not more than 18 inches high, gradually sloping to the north, Mr. Hughes always mixes a little open and sandy soil with the manure, as it assists in regulating the heat more, preventing too great a heat, and maintaining it longer. In spawning, good sized lumps of spawn are inserted from 9 to 10 inches apart, and the soil is not placed over the spawn until the temperature of the manure has become regular, and what is required. After that the surface is kept moderately moist. The only covering to these beds is a thin layer of long straw and one layer of close Russian garden mats. Cutting commenced at the beginning of April, and a good supply of large fleshy Mushrooms have already been gathered, and judging from what are just now peeping through, and the network of mycelium in the beds, a big crop will continue. There are also out of doors quite a couple of dozen small cone-shaped heaps of manure, spawned and covered with litter, and these are just coming into bearing. It is altogether another instance of Mushroom-growing made easy, and Mr. Hodges obtained in great part the idea of how to do so from reading Mr. Wright's excellent treatise, "Mushrooms for the Million."—D. S. H.

— **SUMACH AS A MATERIAL FOR PAPER PULP.**—Allow me to direct attention to the Staghorn Sumach (*Rhus typhina*), and the Smooth Sumach (*R. glabra*), as pulp-producing shrubs for the manufacture of paper. The Sumach tree or shrub approaches to the herbaceous tribes in the glandular construction of its rind and in its pith, and the fibre of its shoots is whiter and lighter than Poplar. As it is readily propagated from shoots or sprouts it may be cultivated with profit on rugged and rocky grounds. The first year's shoots should be cut for pulp-making before they begin to wither, when the leaves are full of sap, and especially before frost. They should be stripped of their leaves, which after being wilted in the sun are spread upon shelves or racks to dry in a shaded but airy place for a month, and in damp weather longer, before going to market. Sumach sells, after grinding, at from 40 dollars to 50 dollars per ton. The rind should be scraped off clean from the shoots immediately after stripping them of their leaves, and dried in a similar manner, and the shoots should be dried and stored away to be sold to the pulp miller. The leaves and the rind of the Sumach contain a tanning and dyeing material having the same properties as galls, its chief consumption being in cotton dyeing. The

roots of both of these varieties of Sumach have hitherto been considered troublesome in sending up suckers, and the prevalence of common or smooth Sumach was evidence that the occupant was a poor and thriftless farmer. The velvety crimson berries of the smooth Sumach are also used in dyeing. They are astringent and of an agreeable acid taste, for which reason they are sometimes used as a substitute for lemon juice, for various purposes in domestic economy and medicine, and to turn cider into vinegar. The acid is the bi-malate of lime.—A. K. (in *Toronto Globe*).

— **THE WEATHER LAST MONTH.**—April was a dry month, but with only very few bright days, and severe frosts on 1st, 2nd, 4th, 5th, 11th, and 12th. Wind was eastward sixteen days. We had lightning on the 7th at night. Total rainfall was 0.82 inch, which fell on eighteen days, and the greatest amount in twenty-four hours was 0.15 on the 15th. Barometer—highest, 30.38 at 9 A.M., on 1st; lowest, 29.35 at noon on 25th. Highest shade temperature, 65° on 30th; lowest, 21° on 2nd; lowest on grass, 20° on 2nd, 5th, and 11th. Trees coming into leaf fast after the 20th, when the wind changed to west at 12 noon, after a long time in east and north-east. Horse Chestnuts almost in full leaf at the end of the month. Swallows arrived on the 30th, nightingales on the 24th. The severe frosts during the month have cut the early fruit blossoms here very much, especially Peaches and Plums on walls. The garden spring ran 23 gallons per minute on 30th. —W. H. DIVERS, *Ketton Hall Gardens, Stamford*.

— **THE TOTAL RAINFALL AT CUCKFIELD, MID-SUSSEX,** for the past month was 2.89 inches, being 1.14 inch above the average. The heaviest fall was 0.75 inch on the 25th. Rain fell on fifteen days. The highest shade temperature was 64° on the 15th and 30th, the lowest 30° on 12th and 13th. Mean maximum 52.2°, mean minimum 37°, mean temperature 44.6, partial shade reading 2° above the average. A heavy thunderstorm occurred here at noon on April 26th, accompanied with a destructive hailstorm, which has done much damage to Pears in bloom and to all tender foliage. It came down for half an hour, and laid on the caves of hothouses and in sheltered corners for several hours. Result in rain, 0.54 inch. Fortunately it was quite local, not extending westward to the parish church, nor to Hayward's Heath southward. Apples look very promising, and not forward enough to be damaged. Vegetation about eight days in advance of last year.—R. I.

— **READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—A large and representative meeting of this Association was held on Monday at the British Workman. This was the closing meeting of the spring session, and proved a good finish to what has been a very successful series of meetings. The President, W. I. Palmer, Esq., J.P., presided, and in the course of his remarks referred to the Association as a school of gardening of great value to the members. The subject for the evening, "The Gloxinia," was introduced and ably dealt with by Mr. Jas. Martin (Messrs. Sutton & Sons' skilful cultivator). Having referred to the introduction of Gloxinia maculata in 1739 from South America, Mr. Martin traced the progress made up to the present time, the beautiful varieties now in cultivation being worthy of a place in every collection of plants. He clearly explained the details of culture requisite to achieve the best results, and exhibited several varieties of these lovely flowers, which were notable for their large size and rich and varied colours. The display of Gloxinias annually produced in Messrs. Sutton & Sons' nursery at Reading is of a high order of merit. Among the exhibits on this occasion was a magnificent specimen of Vanda tricolor profusely flowered. This was exhibited by Mr. Pound, gardener to G. May, Esq., Caversham, who also exhibited some very large Laxton's Noble Strawberries. Two good examples of *Odontoglossum Peseatorci* were shown by Mr. Dockerill, gardener to G. W. Palmer, Esq. Heartly votes of thanks to the President and the lecturer brought a very enjoyable evening to a close.

— **EXOTIC PLANTS IN CORNWALL.**—In a little pamphlet entitled "Cornwall as a Winter Resort" (W. Brendon & Sons, George Street, Plymouth), the following passage occurs relative to the plants which succeed in the open air:—"The latest and fullest account of the exotic plants of the West of Cornwall will, however, be found in a paper by Mr. Upcher, which obtained the medal of the Falmouth Naturalist Society at the Polytechnic Exhibition in September, 1889. The localities chiefly cited are Tresco, Seilly—where, judging by its patent results, the climate, save for the absence of excessive summer heats, may fairly be described as sub-tropical—the neighbourhoods of Penzance, Falmouth, and Penryn. Aralias are perfectly hardy, and

range up to 25 feet high, and 10 to 15 feet through, as at Tresco, Tremough (Penryn), and Redruth. Acacias reach 30 feet at Pendrea—the seat of Mr. W. Bolitho—and Redruth. *Aloysia citriodora* occurs 8 feet high, and with stems 4 inches through. Aloes and Agaves thrive well in many localities, though Tresco has the finest collection. They thrive almost everywhere, but flower with great beauty at spots like Penzance and Falmouth, reaching over 20 feet high. *A. candelabrum* flowered at Falmouth for the first time in England, and reached a height of 24 feet. *Aster argophyllus*—the Australian Musk—has grown 20 feet high at Rosehill, Falmouth. The Norfolk Island Pine not only grows but flourishes at Tresco. The Bamboos do well in such localities as Tresco and Penzance. *Bambusa mitis* grows finely at Tresco; *B. calcata* is dense in the garden of Mr. T. B. Bolitho, M.P., Penzance. The Cannas, too, give a ‘most wonderful group,’ 12 yards round, at Trewidden; and with slight protection the most tender can be successfully grown. *Clianthus puniceus* often flourishes in exposed situations. At Tredarvah the stem of one is 8 inches round. *Chamærops*, in three varieties, reaches 10 feet in height at Polwithen; and *Desfontainea spinosa* 7 feet at Falmouth. *Dicksonias* flourish exceedingly; *antarctica* has grown for twenty years out of doors, and *squarrosa*, brought from a greenhouse in Guernsey, has sprung up 9 feet high in the open at Penzance. *Dracenas* thrive so well that there is actually a native hybrid—*Scillonensis*—originally raised at Tresco. The *Eucalypti* do well. At Penmere, Falmouth, there is one over 60 feet high, producing seed annually. *Escallonia macrantha* is so luxuriant as to be almost a weed; and *Fuchsias* grow to bushes 10 to 15 feet in height, and in various parts of West Cornwall literally form hedges, which flower most lavishly. *Hydrangeas* flourish everywhere in the county, and at Tresco the woods are full of them, ranging up to 10 feet high. The *Lapageria rosea* has clothed a wall of Trewidden, Penzance, while the white variety grows magnificently at Carhayes. Another tender exotic which flourishes exceptionally in Cornwall is the *Mclianthus* major. The Date Palm grows at Tresco. *Camellias* and *Rhododendrons* luxuriate in many localities. *Trevarrick*, St. Austell, has long been noted for the former; and the display of the latter at Tremough, Penryn, is unequalled. The *Thujas* at Penjerick, Falmouth, are the finest in the kingdom; *Yuccas* are thoroughly hardy almost everywhere, and as to *Veronicas* they grow to trees 15 feet in height, while *Pelargoniums* cover the fronts of houses at Penzance and Scilly, and flowering *Myrtles* abound.”

—**ANGLICISED BOTANICAL TERMS.**—In one of the Bombay Natural History Society’s papers, Mr. G. Carstensen, Superintendent of the Victoria Gardens, Bombay, makes a bold suggestion for facilitating the study of botany in India. His experience, he says, has taught him that the study of botany is far more popular in the northern countries of the European Continent than in British possessions, and he cannot help thinking that this fact may be clearly attributed to the difference in the botanical terminology. While the terms used in English works on botany are too frequently quite unintelligible for the layman, because they are in most cases Anglicised Latin words, the terms used by German and Danish authors are generally easily comprehended, because they are translated into the mother language, refer to objects of daily life, or are derived from the language itself. He therefore proposes that the Botanical Committee of the Bombay Society be requested to revise the existing terminology, and to substitute English and intelligible terms for the more unintelligible ones. He gives a few examples of the English substitutes he proposes. The natural arrangement of plants consists of two large divisions, *Phanerogams*, or “flower plants,” and *Cryptogamous plants*, or “spore plants.” “Flower plants” are again divided into *Dicotyledons*, or “two-seed-leaved.” The “two-seed-leaved” in the same way are divided into *Angiosperms*, or “seed vessel plants,” and *Gymnosperms*, or “naked-seeded plants,” and so on. For the “natural orders” he would substitute existing or new English names, and for “genera” he would substitute “forms.” In a complete flower the calyx would become the “cup,” the sepals “cup leaves,” the corolla the “crown,” the petals “crown leaves,” the cup and crown together, now known as the perianth, would be the “floral cover,” and so on through the andræcium and gynæcium, and the whole anatomy of the plant. The adoption of this method would, Mr. Carstensen thinks, “vastly increase the number of students of botany, and in the end would materially further the progress of this unfortunately neglected science.”—(*Nature*).

SOUVENIR DE LA MALMAISON CARNATION.

THIS splendid *Carnation* is neither so well known nor so much grown as it ought to be. The large size and delicate perfume of its

blooms render it extremely valuable for cut flowers, and as a decorative plant it is not to be despised. Its general treatment is simple. It can be propagated by layering or by cuttings made from the soft side shoots, which will root at almost any season of the year. The cuttings should have two cross slits through the base, as this facilitates the formation of roots and lessens the risk of damping. We have found plants obtained from cuttings inserted in sandy soil in a cold frame in August to be the best, being much more robust than those struck in bottom heat. The frame should be kept quite close and shaded during very bright sunshine. All that is required during the winter is protection from frost. By May the young plants will be well rooted, and should be planted out, about a foot apart each way, in an open border where the soil is of a good description, a little rotten manure and leaf mould being added. Pinch out the points when the plants are established, and attend to watering during dry weather. In September they may be placed into 6 or 7-inch pots, in good fibrous loam to which a little well-decayed manure, leaf mould, and sand have been added. The drainage must be well attended to, as stagnant moisture is fatal to this plant. The plants should now be furnished with five or six shoots, which will throw up flower stems during the autumn and may be brought into bloom as required. Those for winter flowering should have a temperature of from 55° to 65°. Such as are required for later flowering should be kept near the glass in a light airy house, and merely protected from frost until required for bloom, when they may be removed to a warmer house. When the plants are throwing up their flower stems an occasional supply of soot water will be found beneficial. The flower stems should be cut out as soon as possible after flowering to prevent the plants becoming tall and ungainly.

In May the plants should be again turned out in the border, or they may be potted and stood in cold frames to which air is admitted on every possible occasion. Those potted will bloom much earlier in the autumn than those planted out. The only insects that are at all troublesome are aphides, which may be destroyed by fumigation or by syringing with soapy water.—R. G. K.

FRUIT PROSPECTS.

THE prospect of a good fruit crop in this district was much better early in the season than it is now owing to the ravages of birds. Gooseberries, Red, White, and Black Currants all showed well, but bullfinches and sparrows have really cleared the first two in spite of soot and lime; the latter are showing well. Plums on walls did not show well on bush and standard trees; they were much better, but nearly all gone with birds. Pears were well set with buds, but the birds have taken all that were not netted. *Marie Louise* on south wall and *Uvedale’s St. Germain* on a north wall are showing best. Apricots and Peaches are not satisfactory, and most of them were lifted last autumn. Apples—most varieties showed well—but as the buds were bursting they have been eaten by starlings, thrushes, and blackbirds, a thing I never saw before. Cherries, Morellos and others, show well, and have escaped so far; Medlars, not a bud left on two trees; even a *Pyrus japonica* was cleared. I am astonished the sparrows have not touched the Peas this season, while last I had to protect all young rows. Would steeping them in paraffin have anything to do with it?

Apples in orchards are showing better this year than they have done lately, and there has not been a good crop the last four years I am told; but many of the trees are old, covered with moss and lichen, and poor varieties, suitable only for cider. I enclose you samples of the Apple blooms destroyed, and would be glad if you could suggest a remedy. I have only been allowed to use the gun lately.—J. MILNE, *Camerton Court, Bath*.

[The remedies are: the gun for the birds, petroleum or lime in winter for the moss, and grafting for better varieties of fruit.]

HERE we are not very favourably situated for the finer kinds of fruits, being on the northern slope of a range of hills running east and west. The climate is mostly rather damp and cold, and trees are very liable to get covered with lichens and canker. Apples are the only fruits we grow on standards, as Pears, Plums, and Cherries do not come to perfection on standards except in exceptionally fine seasons, which unfortunately are few and far between, last season being the most favourable we have had for years. The wood ripened well, with the result of an abundance of blossom on all kinds of fruit trees and bushes. Apricots began to burst their flower buds about the end of February, and on the 3rd of March there were 15° of frost, which has destroyed all the blossom except a few that lay against the bricks. Peaches were eight days later in bursting their buds, which was in their favour, as they are well set. I always cover the Peach and Nectarine trees with old herring nets, which I leave on until the fruit is well stoned, as I find damage results to the tender fruit if taken off sooner. But this year I unfortunately was too late in putting the net on the Apricots. Plums are setting well, notwithstanding we have had about a week of frosty mornings, on some mornings as much as 7° of frost, and during the day a bright sun and cold east wind; but I see it has damaged a good many blooms on the early Pears. Nevertheless, I think there will be a good crop uninjured. Apples are now opening their flowers, and I expect they will be safe unless the frost is very severe hereafter. Cherries, except on the south wall, are not in bloom but look well. Gooseberries and Currants have a good appearance, and for once the bullfinches have left them alone. Last year they scarcely left a bud on

them. I cannot say the sparrows have ever touched the fruit buds here, but as soon as Peas are through the ground they commence nipping the tops off the leaves. — GEO. GALLAHER, *Kilkerran Gardens, Ayrshire*.

CARLUDOVICA PALMÆFOLIA.

WHEN Messrs. B. S. Williams & Son, Upper Holloway, exhibited a specimen of this plant at the meeting of the Royal Horticultural

deeply divided, and the divisions 4 to 6 inches across. It is a fine lovely green, and the arching leaves give the plant a graceful appearance. It will succeed in a stove or intermediate house in a compost of peat, loam, and sand.

The *Carludovicas* are easily mistaken for Palms, which they closely resemble, but they are regarded as the botanical allies of the Screw-Pine (*Pandanus*) family.

FIG. 58.—CARLUDOVICA PALMÆFOLIA.

Society on August 27th, 1889, the Floral Committee at once awarded a first-class certificate for it, a recognition that was well deserved, as the plant will evidently prove most useful. Several fine *Carludovicas* are in cultivation, and occasionally make their appearance at exhibitions in collections of fine-foliage plants, where they have a capital effect. They are also sometimes employed in sub-tropical gardens, particularly *C. palmata*, which is of strong habit and well suited for that purpose.

The species represented in the illustration (fig. 58), kindly supplied by Messrs. B. S. Williams & Son, is one of the most elegant known, producing leaves 2 feet long and 1 foot wide at the broadest part

THE CARNATION.

(Continued from page 340.)

[PRIZES for essays on the *Carnation* having been offered through the Ealing Gardeners' Improvement Society, Mr. Charles Turner, the adjudicator, awarded the first prize to the following useful contribution of Mr. David Cooper, foreman, Gunnersbury House, Acton.]

Layering, as I have already said, is the surest method of propagating, and should be commenced about the last week in July. By that time the blooms will be out, so as to decide upon any sorts that were doubtful as regards their value. There are some sorts more difficult to root than

others. These should be begun first, and follow with others until finished, which should not be later than the end of August. After that I do not consider it would be safe, although I have seen some, especially the old red Clove variety, root freely when layered in the middle of September, but it would not be advisable to leave them so late. The day before layering is commenced, if in pots, they should have a good watering, as afterwards this can only be done through a fine rose on account of the layers; and the same should be applied to plants in beds and borders if the weather has been dry any length of time. When layering in pots little of the surface soil should be pricked up, and a little of the compost advised for cuttings should be added. Then trim off some of the under leaves next to the roots, using a sharp knife, on the under side a little below the second or third joint make a cut horizontally right through one joint, dividing the stem half way through as it goes. Cut the end of the tongue carefully off close to the joint, if left on it might cause it to decay. The tongue should then be fixed downwards in the soil, and secured firmly with a peg made of wood or fern. Then cover the joint with some of the fine soil, and should it at any time become washed bare, more should be added. In about six to eight weeks they would be ready to pot into 60's, large or small according to the size of the plants, and if cold frames are available, where they are intended to be kept through the winter, they might be taken straight away, providing that they are well exposed to the sun; or they could be placed outside. In either case they should be stood on coal ashes to keep the worms from working in the pots. If placed outside they should not remain out after about the middle of October, when they must be taken to their winter quarters. This mode of layering would apply both to pot and border plants, but their general cultivation will be dealt with separately.

Soils.—The Carnation is found to grow best in a loamy soil of a sandy nature, and if the plants are expected to thrive satisfactorily, some pains ought to be taken to secure that which is best adapted for their culture. Loam, which is one of the most essential factors to produce the above effect, is too well known for me to define here, but its quality varies considerably in different localities. If I were allowed the privilege of choosing my own, it would be from some rich pasture land, full of fibre, and of a light yellow colour, where sheep were allowed to graze over, and which a year or two previous had had a dressing of road scrapings. It should have a pleasant smell when freshly dug, and when pressed between the thumb and finger should feel soft and oily and not sticky. But as loam of the above character is not always obtainable, the only way then would be to get that which has the nearest approach to it. A good test for determining the quality of loam is that the grass is fine and luxuriant, not of a wild, rank growth. Always avoid that which contains iron, which, if closely scrutinised, can easily be detected by the rust-like veins running through the soil, and generally the earth surrounding it is of a dark blue colour.

Assuming that a choice of loam has been decided upon, the next thing will be, when dug and brought in, to get it stacked, which should be done by placing the turf grass downwards, and between each layer give a good dusting of newly slaked lime, using while hot and mixed with soot, in order to get rid of any wireworm or grubs that might abound, which are the most destructive insect to the Carnation, besides the manurial properties this mixture contains. Build the stack and finish off with a ridge to throw off the rain. This stack should remain for eight months at the least before being used.

Sand is another indispensable ingredient, and if obtained from the bed of a river would be ready for use at any time when dry, but generally there is some difficulty in getting it. If it cannot be obtained we should use road sand, which I have already alluded to in the compost used for striking cuttings and recommended to be washed before using, on account of its being impregnated with seeds from weeds growing by the road-side, and would soon become a nuisance if used direct without any preparation, from the myriads of little weeds springing up. If one has failed to procure river sand and has succeeded with road sand, a good plan would be to get in a quantity and throw it up in a heap, or slope it against a wall, using quicklime as advised for stacking loam, letting it lay twelve months before using; by that time anything injurious will be decomposed, when it can be sifted and used as required. If neither of the above mentioned sands are procurable, silver sand must be used.

CULTIVATION IN POTS.

Plants that were rooted the previous autumn and successfully wintered, when starting into growth will require potting. This applies to those intended for the above only. About the middle of March I consider would be the safest time to perform this, but con-

sidering the variableness of our climate it would be best to be guided somewhat by the season. When grown singly the pots best adapted for this purpose would be 32 and 24 sizes (according to the habit of the plants), which are very useful decorative sizes; 48's might be used for weak growing varieties, but when larger specimens are required 12 and 16-size pots should be used, putting three or four plants according to the above rule—viz., in a 12-size pot three strong growing or four weaker growing plants should be placed. While the operation of potting is going on be careful the varieties do not get mixed. To see two different sorts in one pot being different in habit of growth and colour of bloom would look anything but becoming in a good collection. Great care should be taken in crocking the pots. Use a large hollow piece for the bottom covering the hole, not flat tile, as some use, then a few more large pieces, finishing off with smaller, which would secure good drainage, as nothing is more detrimental to the health of the plants than being what is commonly called waterlogged. Cover with the roughest of the compost.

Roughly Broken Loam.—The different ingredients used with this depends much upon its quality. If it is of the character previously described and recommended, horse droppings rubbed through a sieve should then be added, using about one-fourth in proportion, and about one-sixth of coarse sand. If the loam is inclined to be heavy a little more sand might be used accordingly, also leaf mould might be added with advantage to about one-sixth, otherwise I should not recommend it. Before turning it give the whole a sprinkling of quicklime, using a 32 potful to 3 bushels of soil. Here I might add a word or two regarding the horse manure used. As I have said before, it should not be from old Mushroom beds, nor as some growers recommend from old hot-beds, but some that has been specially prepared for the purpose. This can be done by placing a quantity into an open shed, or anywhere under cover, all the straw being previously shaken out, letting them lay for six months before using, turning them occasionally to sweeten and assist decomposition. When the soil has been turned several times so as to get the whole well incorporated, the pots should be filled to the required depth, carefully turning out the plants, removing the crocks, and should the plants have become root-bound the roots should be pricked out with a sharp-pointed stick, then place the plants in position in the pot, making the soil firm with the potting stick, and when finished the ball of the plant should be covered with about half an inch of the new soil, which should be $1\frac{1}{2}$ inch from the rim of the pot to allow room for water. The soil when used should not be too wet, rather spread it out and leave it a day or two. If potted in that condition the soil will become clammy, which should be strictly guarded against to insure good results, as it prevents the water passing through the soil, and besides, in a short time will crack away from the side of the pot, hence be very misleading in watering, as the plants might be wet when appearing to be dry, and would moreover lead to anything but good results. Neither should it be too dry, or the plants will require watering as soon as potted, which should not be the case. When potted they should be placed back into the cold frame again, giving them a sprinkle all over with water through a fine rose, and if the weather be favourable it might be repeated occasionally, but if the soil is in the proper condition it is all they will require for ten days at least, unless they show any signs of flagging, when they should have a good watering through a coarse rose, taking care they get soaked through. After that they should be watered very carefully, testing each plant, and watering only when they really require it. During the time that the plants are in the frames after potting they should be well ventilated, and as soon as they start to make fresh growth they should be stood outside on coal ashes fully exposed to the sun, but sheltered from high winds if possible.

When they begin to send up their flower spikes they should be staked at once, and all leading growth should be secured, to prevent being broken by the wind. If the plants show more than one flower spike, the strongest should be selected, the rest pinched off, to throw the whole strength into the one main stem. To flowers that are intended for exhibition, or if large blooms are aimed at only, the buds should be thinned down, leaving two on a weakly stem and three on a stronger one, but for ordinary culture almost all the buds may be left, simply taking out weak or deformed ones. The thinning operation should be done almost as soon as the buds are formed, leaving, of course, the most promising ones.

As soon as the buds show signs of bursting they will require constant attention, as sometimes they open very irregularly. In order to prevent this a piece of matting should be tied carefully round, or small elastic bands could be used, which are made for the purpose and sold by most

nurserymen, and which I consider would be preferable, as they would allow the buds to swell, and not want easing from time to time as matting would as the buds increase in size. If the calyx is inclined to burst on one side, slit the opposite side in two or three places, to make the blooms symmetrical. In crowded buds it would be best to ease it in time by just slitting the calyx in the several scallops marked at the top, so that the guard leaves will fall regularly all round.

Protection from Rain.—As soon as the Carnation begins to unfold its blooms it should be protected from the rain and scorching sun. This must be done if the blooms are to be brought out to perfection. On no account should any water be allowed to touch them. The greenhouse or conservatory would be the most suitable place for that purpose. The front stage of the former would perhaps be the better of the two, as generally at this season of the year some of the customary plants are set outside in the open air; and besides, sometimes the conservatory is badly situated for the well-being of the plants. But should it contain a front stage, where they can get plenty of light and air, they could be placed there by themselves, or mixed with other plants to suit the appearance of the place. In either case they will require shading during the hottest part of the day, say from about nine or ten o'clock in the morning, according to the weather, removing the blinds in the afternoon according to the position the plants occupy, giving as much air and exposure as is practicable without injury to the blooms, keeping a sharp look out for grubs and earwigs. If it is not convenient to house all the plants some lights might be temporarily placed over those outside to keep the rain off, and shaded as previously advised; by so doing they will keep much longer in bloom than otherwise.

Staking the Plants.—In doing this a neat straight stick should be used to each stem, looping each bloom separately, having each stick the same height as the stem. If small hazel sticks are available so much the better, as they are less conspicuous than white sticks, or even if they are painted green; the latter could be used if hazel cannot be procured.

Liquid Manure.—This might be used occasionally to an advantage, which will materially assist them to bring out their blooms true to their character. This should consist of sheep manure put into a bag and allowed to soak in a tub, dipping it out and diluting it according to its strength. It must never be used very strong, and only when the pots are well filled with roots, and must be withheld when the blooms are nearly expanded. Soot water might also be used accordingly. When the plants have finished blooming they should again be brought into the open air for layering, except those that have seed pods and are intended to be saved; these should be given a light airy place exposed to the sun to ripen the seed. An early vinery that is usually thrown open at this season and the Vines partially pruned would answer admirably.

CULTIVATION IN BEDS AND BORDERS.

This popular method of cultivation is resorted to in some degree by almost everyone that owns a garden; and doubtless some varieties do better in the open air. Of course, they are not so much under command as when grown in pots, but in ordinary seasons an excellent display can be made when grown in well prepared beds and borders, and on the trouble bestowed on them in making depends to a great extent the amount of success that will follow, also upon the value set on the plants. The general idea of making a Carnation bed, and which is mostly given when advice is sought from growers, is, should the soil be heavy, give it a good dressing of road scrapings, dusting it well with soot and lime, turning it up rough for the winter prior to planting in the spring. If the soil is of a light character be more sparing with the road scrapings, but a good mulching of horse droppings might be added. This advice is very good for ordinary culture, especially if the soil is of a fairly rich loamy nature. But if the soil does not answer to the descriptions given above, and choice sorts are intended to be grown, the better plan would be to make a fresh bed or border altogether, which would be more likely to insure success if good blooms are desired. If this has been decided upon the first step will be to take out about 1 foot in depth of the old soil and fork up roughly another foot, provided there is that depth from the subsoil; over this spread about 4 inches of horse droppings; an old hotbed would answer for this purpose if composed chiefly of the above material. Then fill up with the soil previously advised for potting; only it may be used in a little rougher state, finishing off with some of the finer, and raising it about 6 inches above the permanent ground.

Borders should be brought sloping gently to the front, but beds are raised in the middle and the top rounded, bringing down each side in the same manner, just enough to give the water a gentle fall. The plants should be when planted out singly 10 inches to 1 foot apart, but if in pairs they should be 15 inches from plant to plant to allow room

for layering. I mention pairs, as some growers adopt that method from an economic point of view, and planting as such would prevent the plants being split apart. About the end of March or the first week in April is usually the best time to perform the above operation. In regard to protecting the blooms from rain I shall say very little, as that will depend entirely on the value set on them, as appearance generally predominates in bedding. If desired they can be protected in the same manner as advised for pot plants outside, or by bowing sticks over them and stretching canvas over would answer the above purpose. The same precaution must be taken as to the slitting the calyx, as they are more liable to burst irregularly than when grown otherwise; if neglected the calyx will split on one side following on down to the base of the pod and so disfigure the blooms. I hardly need say that the plants will require frequent watering during hot dry weather, also staking, weeding, and stirring the surface of the soil occasionally to prevent its becoming hard, thus not allowing the water to penetrate it, besides giving a neat appearance.

THE DESCRIPTION OF A GOOD CARNATION.

The value of a good Carnation is estimated by the perfect construction of its petals, and distinctness as to the various shades and tints. In a perfect bloom every petal should have its own distinct colours peculiar to its class, and the more bright and distinct the nearer approach they are to perfection. When the bloom is fully developed the base of the cup or calyx should remain intact, without bursting in any form whatever. The external or guard petals should be large, evenly set, not overcrowded, and without blemish of any kind. Neither should the bloom be overcharged with the inner petals, nor too thin, but sufficient to give it gradual ascent, forming, as it were, a crown in the centre, each petal being even and rising one over another in regular order, and tapering to the centre. Each bloom should be perfectly round, the petals having a wax-like appearance, and being of a stout texture. The fragrance of a bloom will also add to its value. In some Carnations this quality is more perceptible than in others, but all possess it to some degree. It seems to be most prevalent among scarlet bizzars, where the Clove stripe recurs frequently in the petals, also among tree or perpetual varieties.

Run Flowers.—These are flowers running from their naturally disposed colour which characterise their different classes, and flowers having a tendency to that freak lose all advantages as regards exhibition purposes, and occasion great disappointment to the grower, as when a bloom once sports it rarely ever returns to its true character again. Anyone who has grown a collection of Carnations and studied their character would have noticed the above peculiarities about them. But why they are possessed with such there is a great difference of opinion, and I must admit that I am not prepared to explain. There are some sorts more subject to run than others; in some it is very slight, but generally it is very decided; e.g., a scarlet flake will sometimes change into a plain scarlet, or a bizarre into a self-coloured flower. Some have an idea that it is brought about by overfeeding, and I am inclined to think it is to some degree, but sometimes it occurs in flowers when grown in poorer soil, and do what you may, in so many shades there will be always a certain amount of running. Some scientists try to explain the cause by the plants going through a process of unmixing of colours. Be that as it may, I believe it can be prevented to some extent by a little more attention given to the soil used for those particular sorts that are apt to sport. Instead of using the amount of horse droppings previously advised, take about half, and add the same quantity of lime rubble, run through a sieve, and well mix with the other ingredients.

(To be continued.)

TOMATO CULTURE—PREVENTION OF DISEASE.

I AM a great lover of Tomatoes, and a firm believer in the old adage, "Prevention is better than cure" respecting Tomato disease. But as to the Tomato fungus—a relative of that affecting Potatoes, for neither do I think there is any specific cure—prevention must be looked to. The syringing with sulphates, even if not inimical to the foliage, cannot be expected to enter into and eliminate the fungus from the tissues. Everyone knows when the well-known spots come on Potato haulm the fungus has got through and through the stem so affected. External applications are so much time and money wasted. 'Tis so with Tomatoes. Last year at the back of my greenhouse I planted two plants of Carter's Perfection and Blenheim Orange at the moist corner, so to speak, and two more of the same varieties in the drier and warmer south-east corner. To make matters worse for the western end where the Tomatoes were planted some drip came from an interstice in the overhead ventilator. Very soon a mildew-like fungus appeared, probably

Cladisporium, and this was followed by a white-winged aphid, though I cannot say the latter did much harm. Both ultimately, but not until the end of the season, spread to the healthy plants that were dry and warm throughout, but, strange to say, made so little progress as to do them no harm. Further, I had Ferns, some of the hardier Orchids, &c., in the moist end, and did not mind giving air so frequently. This had an injurious effect on the west-end Tomatoes too, and of the limited number produced neither in size, number, or quality could they compare with those grown at the other end that were more exposed to sunshine, a freer current of air and drier air, and that had water less frequently. Outdoors, from plants grown in different positions, I arrived at about the same conclusion, and which may be summarised—1, A tolerably dry warm soil, with a mixture of lime rubbish and brick dust, sand, &c., through the loam and leaf mould. 2, No fresh or very rich manure, and if the soil is fairly good better depend on an artificial dressing after the fruits are set. 3, The freest current of warm air and the fullest available sunshine, and no shading by any means. 4, Proper thinning of the unnecessary side shoots and foliage, so as to expose the fruiting stems to full sunshine. 5, As this is a good time for planting water very slightly, plant in good warm soil that had been exposed to the sun, and if water must be used now and then let it be warm or heated in the sun. Precaution is better than cure; thus disappointment and subsequent vexation is avoided.—W. J. MURPHY, *Clonmel*.

NOTES ON AURICULAS AND SHOWS.

It is not an easy matter to criticise a show of florists' flowers, however well one may know them, and this is more especially the case with a flower of such a peculiar character as the Auricula, for I am afraid it must be said, like olives or oysters, it is an acquired taste. "Oh! yes, I have no doubt very beautiful, but very prim and stiff; I really cannot work myself up to admire these flowers," is what one is often doomed to hear, and the amused wonder with which one of the ordinary frequenters of shows will stand by and listen to the enraptured exclamations on some "general favourite" is very delightful. Thus when I was with an excellent judge and grower of Auriculas comparing two green edges the other day, a bystander said, "Well, it must require a connoisseur to see any difference between them." They were very distinct, and we were not examining them for that purpose, hence many a lover of flowers will consider all criticism on the subject useless. Then there is the lover of herbaceous plants, who has a sneering contempt for anything that is the subject of laws and rules. There are species of Auriculas and Primulas, and he so revels in these that he very much wonders why people should trouble themselves about what is a violation of Nature, and from the pinnacle of his æsthetic majesty looks down on the florist with simple wonder and amazement. And then last and worst of all there are the florists themselves—good genial fellows most of them, but terribly afflicted with corns, and by no means soft ones. Now, if in your criticisms you deem it necessary to find fault you may expect such a look and growl as I should myself indulge in if anyone trod on my toes. Now, if anyone in any of these three classes find fault with what I have to say about the Auricula Show I give fair warning it will pass by me as the idle wind, which I respect not. I have no object to serve but the welfare of a flower I have loved from my boyhood, and which now that I have passed man's limit has still many charms for me, and brings up pleasant mementoes of the days long ago.

Not that I have much adverse criticism to make on the National Exhibition, which in its extent somewhat surprised me. To me one of the most satisfactory features of the Show was that it was so much more a southern one than it used to be. The northern growers, with the exception of Mr. Horner, were not there. Messrs. Ben Simonite, Bolton, Potts, Penson, Wilson, and others, whose flowers used at one time to fill the tables, were absent. I suppose in some cases the lateness of the season kept them back, for I am glad to find that growers are coming back to the notion that forcing Auriculas into bloom does not pay. Be this as it may, it was a real pleasure to find that southern growers were coming on, and that too in very dashing style. I remember in former years how I used to regard Reading as the home of one of our greatest florists, one who helped so much to raise the Show Pelargonium to the pitch of excellence it has attained, and now the same town seems as if it would make a name for itself amongst Auricula growers. A few years ago Mr. Henwood was unknown by name, now he ran the great Auricula champion Mr. Horner so close that it was a very difficult matter to decide, while in the class for six Auriculas he took the first place. Now all this is as it should be, although I once despaired of ever seeing it accomplished. I do not think one southerner exhibits in the northern section, and therefore it is only right that the lion's share in the southern show should fall to the southern growers.

I do not think that the quality of the flowers was at all up to the standard of excellence we have sometimes seen, nor do I see how it could be otherwise. It was a late season, and hence such flowers as George Lightbody, Lancashire Hero, and Prince of Greens, which are long in opening, were but scantily represented. Then there was that spell of cold weather in the latter end of March and beginning of April, which tended very much to chill the bloom, and consequently there was a large number of crumpled edges, and what someone has called distressed blooms. Nor were the trusses so large as in many seasons. Of this latter I do not complain, for I believe that a truss of seven pips of an edged flower is the most symmetrical one can have,

but where a truss bears many there is the greater facility for cutting out bad ones and leaving perfect pips; and although I do not hold with the practice of cutting all out to get three perfect ones, still one may err on the other side. Some varieties give larger trusses than others, but it is to me no recommendation to a truss that it contains ten, eleven, or twelve pips. Another point, I noticed much less drawn foliage than used to be the case. This most probably arises from the disuse of heat, which has a tendency to draw up both foliage and flower stem. As far as my judgment went Mr. Henwood's plants were the most compact and in every respect the most orthodox in the Exhibition; his plants reminded me of what Mr. Penson's used to be in the old South Kensington days.

The interest, of course, is mainly with the newer, although to a certain extent this is of a provoking character. You see a very fine new Begonia, or Pelargonium, or Chrysanthemum; you make a note of it, and say to yourself "I mean to have that," and in a reasonable course of time you do get it. But you see a new Auricula, you admire it; you say to yourself, "I should like to have that," but you may have to wait till your hair turns grey before you do. Mr. Horner has been raising seedlings for years, has gained prizes for them, has caused the mouths of fanciers to water, but oh! how few of them have found their way into commerce, not, I must suppose, from any unwillingness on his part, but on theirs. Some kinds will remain year after year without throwing an offset, and although cutting off the heads has been advised, I fancy but few try it.

Of the flowers which are to be had the best were Heroine, a beautiful self, possessing all the requisites of a good flower, and perhaps eclipsed by the daughter Mrs. Potts, raised by Mr. Sam Barlow from seed sent him by Mr. Horner. The Rev. F. D. Horner (Simonite) is a fine green edge, and it must be so, as it took the premier prize, beating a good plant of Leigh's Colonel Taylor and Trail's Prince of Greens. It has a defect (what Auricula has not!) in a certain thinness of paste through which the body colour sometimes shows. This is conspicuous in Litton's Imperator, from whence this flower (although I only write from surmise) would appear to have come. It is no small credit to the intelligence of my late excellent friend, Mr. Woodhead, whose loss to floriculture was, I am sure, a great one, that four of his flowers should have appeared in the winning stands. Thus Mr. Horner, in his first prize stand of twelve, had Rachel (a grey edge), while Mr. Henwood had in his second prize lot George Rudd, Rachel, and Black Bess, while Mrs. Dodwell was also shown. I am sure it will be a pleasure to Miss Woodhead to find her brother's flowers occupying so honourable a position. Amongst other flowers I liked Monarch, green edge, although it had a little tendency to coarseness. Favourite and Iris, both flowers of the Sapphire type of colour, were very promising. Mélanie, a dark self of good character; Irreproachable, a fine flower, although the paste is somewhat faulty; Miranda, a flower which somewhat reminds one of Conservative; Magpie, a fine white edge, with deep black body colour, I regard as the best edged flowers that Mr. Horner has raised. Mr. Horner had also a yellow self, which all the æsthetics called precious, but which I cannot say I regard with any favour. Desdemona, a white-edged flower, was also good.

I am sorry to say that I have nothing to add about the Alpines. I have tried to like them, have again grown a few, but I am sorry to say that they can never, to my mind, be named in the same breath with the show flowers.

I hope that the success which has attended the attempt to popularise this flower, a success of which I long despaired, will induce others to imitate our friends at Reading. If anyone had said when, a few years ago, Mr. Henwood began to exhibit that he would beat the oldest and most experienced exhibitors people would have shaken their heads. But he has done it, and, as I have already said, ran him very close in the large class of twelve plants. What he has done others may do, and thus a still greater popularity be gained by this flower; and for the encouragement of such let me say I can look back on nearly sixty years of affection for this flower; that it has been, like all things, a source of mingled pleasure and trouble; that I still retain the old love, which not the Rose or the Gladiolus, or any other flower, can supplant.—D., *Deal*.

SPRING FLOWERS AT HOME AND ABROAD.

(Continued from page 339.)

THE BULB FARMS OF HOLLAND.

No one who visits Haarlem, on whatever mission bent, passes the bulb farms by without at least a cursory inspection, and the majority of those who travel thither from England do so for the express purpose of seeing the flowers. Many bulb dealers go over annually to inspect the stocks, others to try and pick up bargains (which often turn out bad ones) at the bulb auctions, and an occasional amateur finds his way across, as much from curiosity to ascertain whether the farms are really something "out of the way" as anything else. In the comments which I purpose making I do not propose to indulge in the stereotyped descriptive matter and nothing more, but rather to single out a few special points of interest which may prove not less acceptable to the readers of the *Journal of Horticulture*.

Haarlem, the home of the bulb, is a name that is written large in the pages of history. For many years the brave forefathers of the Hyacinth growers of to-day had a hard struggle against foreign invaders from various lands. The sword was as familiar to them as the pruning hook, and they fought for home and freedom as sturdily as they had fought to

drag their sandy flats from the devouring sea. Rembrandt has enshrined on his imperishable canvas the stern faces of these heroes of the past, and if their names were effaced from the annals of their native land the brush of the mighty painter would suffice to keep their memory green in the hearts of their descendants. It is curious how ancient and modern Holland are brought into contact by the artist's brush. In looking through the flowers at the great Exhibition at Haarlem a few weeks ago I discovered a favourite old Hyacinth not much grown in England, Kenau Hasselaar. An hour later I stood before a marvellous picture which depicted an assault on Haarlem by the Spaniards, and there was Kenau Hasselaar as she had been in the flesh, her face aglow with savage fire, leading her devoted followers on to the very edge of the battlements, hurling down the scaling ladders of the men-at-arms, wielding axe and halberd with frenzied strength, and pouring down boiling oil and tar upon the ascending foe. Wives and daughters fought side by side with husbands and fathers—the eye that aimed destruction upon the son was extinguished with horrible swiftness by a fiery flood hurled by the mother's hand. One forgets the peaceful pursuits of the present in gazing upon this wonderful presentment of the fierce struggles of the past—struggles that inaugurated the existing era of progress and plenty, and without which an intelligent and contented people would not now be cultivating the soil in order to provide flowers for the adornment of British homes. Under the demoralising rule of the Spaniards the sea would have reclaimed its own, and the rich treasures of the fields would never have attained the development which now makes them of such vast importance in the world of flowers. The painting is fascinating in its vivid realism. The quiet of the Exhibition Hall fades away before it. In place of the soft lines of colour with their pleasing foil of green, beautiful in themselves and not less significant from the lesson that their silent voices teach of the happiness of peace and progress, rise the grim horrors of the fierce struggles that preceded the existing era. The bulb fields were battlefields then, and it needs an effort to break the spell of the picture, to bring the imagination back from the past, and to revive the recollection that if a gardening writer may be pardoned for an occasional excursion from Flora's domain into the realms of Mars, it must only be a brief digression.

Holland, as generally understood by us, comprises the whole of the Netherlands. This is not quite correct, inasmuch as Holland forms only a part of the kingdom of the Low Countries; but it is not worth while to discuss geographical accuracies in the present connection, for the bulb-growing district is actually a part of Holland proper. Haarlem is its centre, and the great majority of the bulbs cultivated on such a colossal scale for exportation are grown between that town and Leiden, distant about twenty miles. These places are reached almost as easily as any great English town, and much more quickly than the north of Scotland. For comfort and economy combined the Great Eastern route *via* Harwich and Rotterdam may be well chosen. The continental train leaves Liverpool Street, London, at 8 P.M., and Rotterdam is reached at eight the following morning, the sea journey lasting a little over ten hours. Trains from the Dutch port travel to Haarlem or Amsterdam in about an hour and a quarter, so that the whole journey lasts but fourteen to fifteen hours. Return tickets are issued available for a month on very reasonable terms, and the question of expense is therefore a by no means serious matter. Whoever is desirous of a holiday may have one full of interest and enjoyment by running over to spend a few days among the Dutch bulbs.

To many untravelled Englishmen foreigners are credited with mysterious ways and guileful customs, to become entangled among which is to fall a prey to abnormal embarrassment and extortion. No such apprehensions need agitate the breast of the visitor to Holland. He will find himself almost as comfortable and as much at home as if he were in England. Should he not find himself in a condition to enjoy a hearty breakfast as the steamer completes the last few miles of her journey in the river Maas, but avoids the dining saloon in order to study the play of light and shade on the surface of the water over the side of the vessel, he can restore exhausted nature at the railway station with something at once cheap and substantial. I would not suggest that any such suspicious occurrence is probable. I merely suggest a ready means of rectifying the effects of a possible rough passage. Nor, should the traveller have been studying Delille or Otto, need he let loose his rudimentary knowledge of French or German upon the unoffending head of the Hollander. To such blandishments as *Parlez vous Français?* or *Sprechen Sie Deutsch?* the reply is frequently a negative shrug; but try him with English, and the effect is usually much more satisfactory. Let it be understood that this does not apply to those of fair social standing. Most Dutchmen of average education know French, English, and German, and with many you might throw in some half a dozen other languages without finding them at fault. It refers to the customs officials, boatmen, porters, waiters, and such like, though the latter sometimes display unexpected abilities as linguists. An inquiry of one with a decidedly Gallie cast of features as to whether he spoke French was answered by the startling reply, "No, I don't speak French; but I speak American!"

Holland proper is not a large country, and the distances from one important town to another are short. From Rotterdam, a remarkably fine and busy town, the Hague (which must be looked for as "den Haag") is very quickly reached, but the traveller in search of spring flowers does not stop here, although as a summer resort it is unequalled. Journeying on he soon reaches Leiden, or Leyden according to English orthography. Here he might stop and visit Mr. de Graaff, a great grower of Amaryllises and Narcissi, or, proceeding direct to Haarlem, work his

way back to Leiden after inspecting the bulb farms in the neighbourhood of the former town. From the latter onwards the bulbs begin to break upon the view. From the middle to the end of March there are sheets of Crocuses; the first, second and third weeks of April millions of Hyacinths, and then towards the end of April and the early part of May the gorgeous Tulips unfold. During the whole of April the fields are clothed in beauty, and both earlier and later than that month there is ample to reward a visit.

So recently as the autumn of last year the methods of cultivation followed by the Dutch were fully described in the Journal by Mr. Alfred H. Pearson, and it could hardly be of interest to re-traverse the ground covered in his admirable paper by giving over again such details of their culture as the Dutch think proper to communicate to inquiring visitors. There are, however, some points which I think may be found worth a few moments' consideration. One that interested me greatly related to the universal custom of removing the flower stems of the bulbs just as the spikes had attained full development. It is well known that this practice is adopted on all the farms, and the general opinion in this country is that there is but one object in view in depriving the plants of their beauty at its zenith—namely, to save the plants the strain of ripening seed, and to aid the development of the bulbs by the power thus conserved being devoted solely to them. This, according to one of the largest growers and exporters at Haarlem, is not the case. The specific object of removing the flowers of Hyacinths and Tulips is, he says, to avoid the petals falling upon the leaves, which occasions spotting, commonly called "fire." When the foliage becomes thus affected its powers of assimilation and elaboration are materially curtailed, and the bulbs are greatly weakened. It must be confessed that my preconceived notions of the primary object of the cutting down process practised by the bulb growers were somewhat upset by this information, and I inquired if the question of saving the strain of seed ripening was not considered of at least some weight. The reply was in the affirmative, but it was added that it is so small a consideration that in the case of Crocuses and Narcissi, which do not become "fired" by the falling flowers, it is not thought worth while to sacrifice the time necessary for removing the latter, and they are consequently allowed to fall. The manner of removing the flowers is merely a matter of convenience. Hyacinth spikes are cut off; Tulips, the stems of which are brittle, are broken with the fingers and thumb.

I have no reason to believe that my informant was practising on the credulity of his English visitor in this matter, and I was informed that the custom and its objects were not peculiar to one individual and practised by one firm, but were of general adoption. In this case we have been supporting ourselves with a broken reed in pointing to the Dutch system in corroboration of our views on removing the flowers of Hyacinths and Tulips, but as regards the merits of the practice our opinion need undergo no change. It cannot be harmful to relieve a plant of the burden of seed ripening; on the contrary, it must possess a measure of benefit, and therefore the practice should be continued.

In walking about the farms and conversing on various points in bulb culture, one cannot fail to be struck by the important part that is played by the disease. Withered plants or ugly gaps show where its fell work has been accomplished. A curious instance of the disease localising itself was pointed out to me on a large farm. One end of a series of beds had been attacked, and the line of destruction was as clearly defined as if the affected portion had been scorched. On this self same spot the disease had manifested itself year after year, the remaining portions of the beds always escaping. The whole of the soil had been removed and fresh substituted, and new stocks of bulbs had been planted, but the disease reappeared with unfailing regularity, until one of the most experienced bulb-growers in Holland had to confess himself completely baffled. Does any reader of the Journal wish to increase his store of this world's goods a thousandfold? Possibly there is at least one who is not in the happy position of having enough and to spare. Then let him study the bulb diseases which perplex the Dutch growers and annually subject them to heavy losses. Let him note effect, study cause, and find a cure, and he will be hailed as a benefactor, and, what is of more importance, reap a golden harvest. During the past six years a new disease has attained serious proportions. It has been carefully investigated by the two Amsterdam savants, Professor de Vries and Dr. Wakker, and I am promised the result of their inquiries when an opportunity arises of communicating them. Although they have, I believe, traced a bacillus, they have not succeeded in finding a means of checking it. Some varieties are affected by this disease to a far greater extent than others. Its presence is readily detected in the beds, and diseased plants are at once destroyed. The roots, I believe, are the points of attack, and they are speedily destroyed, the leaves also changing colour and withering, in fact the whole plant collapses.

There is a serpent, it will be seen, in this bulb growers' Eden. Were they free from the disquieting disease matters would be roose for them just now. Bulbs are in great demand at enhanced prices; in fact, trade is brisk and profitable all round. The latter feature would not be admitted by many. It is a peculiarity of some Dutch growers that every innocent Englishman must be informed that there is no profit in bulb growing. The innocent Englishman sometimes responds with a "smile that is childlike and bland" that he had no idea such business-like people as the Dutch would do so much work from purely philanthropic motives; at which the grower, unless he fails to understand English when he sees that he is being "got at," is moved to the confession that he does "make a little by it, but nothing worth speaking of." It is not so bad in some cases, however. One large grower dis-

poses of 1000 cases per annum, which, at the present increased value of bulbs, will represent at the least £10,000, possibly £15,000. Accepting the former figure, and computing the profit at the very moderate rate of 10 per cent, we have, or rather he has, an income of £1000 from forty to fifty acres of land. Not satisfied with the present prosperous condition of the bulb industry, the growers propose to further increase the price of their bulbs this season. The demand last year was exceptionally good, and they anticipate another heavy sale this year, hence on the principle of making hay while the sun shines they will augment the prices still further. Retribution, however, is inevitable, for sooner or later a reaction must come.

It is not easy to turn over such a tender morsel as the result of the little calculation given above without asking oneself if some portion at least of the enormous number of bulbs imported by this country could not be grown at home. This subject is one of such importance that it could not be adequately dealt with in the few lines left at my disposal in the present article. I will, therefore, leave it, with other matters, for a future paper, premising that we are not without a gleam of hope. —W. P. WRIGHT.

(To be continued.)

FERNS AND FERNERIES.

[Prize essay by Mr. E. Booker, Chiswick Gardeners' Mutual Improvement Association.]
(Continued from page 360.)

FILMY FERNS.—These Ferns are perhaps amongst the most beautiful and interesting of the whole family. In consequence of their requiring a closer and moister atmosphere than can be supplied under ordinary circumstances in the stove or greenhouse, they must be grown in frames, bellglasses, or Wardian cases, and as these cases are now made in so many handsome designs, one of them properly filled with a good variety of Filmy Ferns is no disgrace to the most elegant dining or drawing-room. Care must be exercised in selecting a case to see that the bottom is perfectly lined and sound, and the outlet for the water perfect. On the bottom of the case place plenty of thoroughly clean broken crocks, on these place a thin layer of moss or sphagnum to prevent the soil washing down and choking the drainage. The drainage is a very important point in the cultivation of Ferns in cases. The compost should be free and open, consisting of good fibrous peat, a small quantity of loam, leaf soil, and sand; this should be sifted and the finer particles used for other purposes. Some broken charcoal, sandstone, or pumice stone should be well mixed with the soil after it is sifted. The object of such an open compost is to secure a free passage for water through the whole body of soil, and the free admission of air to the roots of the plants. Where such a compost is used it will be found the best roots are those which lie in the crevices between the pieces of compost. The size of the case must determine the quantity, and what size Ferns it will be necessary to plant. Such as the *Todeas*, especially *Todea superba* and *T. pellucida*, should be planted in pieces of tree stems, and raised a little above the level of the soil, so that their handsome graceful fronds may be seen to advantage. The groundwork may be made up with *Hymenophyllum tunbridgense*, *H. Wilsoni*, *H. demissum nitidum*, and a few of the *Trichomanes*, such as *T. radicans* (Killarney Fern), *T. r. dilatatum*, *T. trichodeum*, and *T. reniforme*; the two latter varieties should by all means have a place found for them. The rhizomes will soon spread rapidly on the surface, and may then be pegged to the Fern stems, and they will grow in this position luxuriantly, covering the stem with their exceedingly handsome fronds. When all is planted water carefully to settle the whole of the plants. Keep them as cool as possible, and shade from bright sunshine. When fairly established they must, the same as other Ferns, have water when dry, and it will greatly benefit them if occasionally syringed during the hot dry weather, as most cases are not so completely air tight as to prevent the rapid evaporation of the moisture.

If the cultural details are carefully attended to I am of opinion that in these cases Ferns will not require replanting so often as every two years, as some persons advocate, for when replanting is done it destroys the chance of any seedlings appearing that might have happened had it not been disturbed. What can be more interesting than watching the little seedlings develop, and to discover to what species they belong? If from necessity replanting must be done, then previous to disturbing the Ferns have a proper supply of clean crocks and compost as before mentioned, so that when the Ferns are lifted everything should be at hand to plant them again as quickly as possible.

OTHER FERNS SUITABLE FOR CASES.—There are several varieties of Ferns exceedingly handsome and less expensive than Filmy Ferns that may be grown in cases. Those I shall mention I have found to do well, and proved to be quite interesting and beautiful. *Asplenium viviparum* if planted in a piece of tree Fern will make an excellent plant for the centre, with the dwarf varieties of *Aspleniums* to help form the groundwork. Such as *A. fontanum*, 6 inches in height, *A. obtusilobum* are also suitable. The last is a dwarf handsome creeping Fern, throwing out a number of runners, which if pegged down will readily root and produce plants, which continue the process. A few varieties of the *Doodias* are also suitable for this purpose. The best are *D. caudata*, 6 inches; *D. caudata* var. *confluens*, 6 inches; and *D. lunulata*, 12 inches. A beautiful and useful Fern for cases may be found in the *Anapeltis*, forming a pleasing contrast to the others mentioned. *A. nitida*, a free growing creeper, rhizomes silvery white, fronds small, undivided, light green. The rhizomes of this species should be pegged to the Fern stems, and will look very pretty. *A. lycopodioides*,

3 inches, and *A. squamulosa*, 3 inches, will grow very freely, and as they have small surface rhizomes they will soon spread and cover the whole surface.

FERNS FOR ROOMS.—Ferns are favourites with cottagers, and consequently have often to be grown in the ordinary room of a dwelling house, but through the dryness of the atmosphere they cannot possibly grow so well as when in a damper place. They are useful for table decoration, also for standing in the window, where they grow better and live longer than any flowering plant that can be obtained. Care should be taken that they are not introduced in a soft immature state of growth from a house where they have been subject to a warm moist atmosphere. Such plants will prove disappointing. They must be regularly supplied with water, the fronds also may be gently sponged or syringed with clear tepid water to remove the dust which accumulates on them. The same may be said of these as of those grown in more favourable positions—only water when requisite, then give plenty, using water as warm as the room in which the plants are growing. If these matters are attended to they will grow, and do much towards enlivening and beautifying the room. The following varieties are perhaps amongst the best for this purpose:—*Adiantum Capillus-Veneris*, this may be placed in a basket and hung in the window; *Asplenium bulbiferum*, *A. cicutarium*, *A. australasicum*, *Davallia canariensis* (Hare's Foot), *Lastrea aristata*, *L. a. variegata*, *Lygodium scandens*, *Pteris argyrea*, *P. serrulata*, *P. serrulata eristata*, *P. tremula*, *Scolopendrium vulgare*, and *S. vulgare crispum*.

THE HARDY FERNERY.—It would not be wise to conclude this essay without touching upon the hardy fernery. But it must be briefly, as this subject would, to do it justice, command one paper alone. If there is room in any garden in which we can make or construct an outdoor rockery, in which we can plant some of the exceedingly handsome species of hardy Ferns, if only a small one, I would say by all means have one, as nothing can give a greater charm to a garden of any size, especially when we consider that some of the hardy Ferns will grow in places in which the majority of other plants would surely die. The first conditions as to the site are, however, protection from wind and provision for shade, these being essential to the majority of Ferns. The mode of construction is entirely a matter of taste, fancy, and space. The material for construction, where expense is not a primary object, should be the same as that recommended for the indoor rockery, namely, tufa. An excellent substitute may, however, be found in burrs from the brick kiln. These may be washed over with some cement and cowdung well mixed together with water, which will make an excellent imitation of stone. Elaborate and minute imitations of actual rock are rarely so effectively done that the illusion is perfect, and if really so, it is in part covered by the foliage when devoted to Ferns. The size must determine the mode of building, and whether we shall require large masses of stone or small. In building let each block recede instead of overhanging, because in this way the plants in the fissures receive the benefit of the rain or dew which falls, and this will be an advantage.

SOIL.—The soil for hardy Ferns should, as with other plants, be properly prepared. If peat, loam, leaf soil, and sand can be obtained, a mixture should be used, or peat may be used alone—it will well repay for its cost. If neither course be possible, mix a little of these ingredients with some good garden soil, but for the small varieties of Ferns I recommend using a good compost. In any case, within doors or without, a rockery for Ferns should contain a good body of soil; if there is any stint there will be no prosperity.

PLANTING.—This, as well as the construction, is a matter of individual taste or fancy. If the rockery is on a large scale, and large masses of it are presented to the eye at one view, either very large individual plants or a group of each of some of the largest kinds may be necessary to secure masses of foliage in character with the massive construction. In arranging the plants generally the evergreen and deciduous kinds should be so planted that when the foliage of the latter dies off for the winter there may still be abundant objects of interest throughout the whole.

The seasons for planting a fernery are the spring and early summer months before the annual growth is far advanced, and the planting should be done carefully and firmly. They must be carefully attended to in watering, especially during hot dry weather. If they can either be syringed or watered with a hose in the evening of hot dry days it will do them good. A little practice will soon enable anyone interested in the matter to master the details of the cultivation of these plants in the garden.

SELECTION.—In giving a selection I shall confine myself to a few varieties that I have seen do well and give satisfaction: *Allosorus crispus*, *Adiantum pedatum* (deciduous), *Asplenium Adiantum nigrum*, *A. marinum*, *Athyrium Filix-fœmina* (Lady Fern) and its handsome varieties—these are all deciduous; *Blechnum spicant*, *B. s. cristatum*, *Ceterach officinarum*, *Lastrea æmula*, *L. grandiceps*, *L. Filix-mas* (male Fern)—these are strong robust evergreen Ferns and very handsome; *Osmunda regalis* (deciduous) requires plenty of water when growing; *Polypodium vulgare* and its beautiful varieties, *Polystichum aculeatum*, *P. angulare*, *P. a. cristatum*, *P. a. grandiceps*, *P. lonchitis* and *Scolopendrium vulgare*, of this also there are some exceedingly handsome varieties.

MARKET GARDENING IN THE SCILLY ISLANDS.

It is a curious instance of the changes of agricultural conditions caused by foreign competition and the opening up of new sources of

supply, that although the growth for export of early Potatoes is still an important industry of the Scilly Islands, it has now been superseded in the financial esteem of the farmers by the cultivation of flowers for Covent Garden Market. Last season no less than 200 tons of cut flowers were forwarded from the Islands to the various markets of England and Scotland by the steamer which plies between Scilly and Penzance, and in a single week of February in this year 20 tons were despatched. Nearly 100 acres in the Islands are devoted to the culture of the Narcissi, and the capital invested in this trade is reckoned at something like £250,000. The following details—collected during a recent visit—of the cultivation of the soil in the Islands, as at present conducted, will, it is hoped, prove of general interest.

General husbandry was never very successful in the Scilly Islands, for up to the time of Mr. Augustus Smith's proprietorship the farmers held their land on such precarious tenure that they refrained from all improvements, and contented themselves with growing a little corn and a few Potatoes, and breeding inferior cattle and sheep. Notwithstanding the introduction subsequently of improved cattle, securer tenures, and larger holdings, farming, strictly so called, failed of ultimate success. It was then that market gardening stepped in, and for a long time proved exceedingly remunerative. The cultivation of the early Potato was one of the chief supports and occupations of the Scillonians, and every available space was planted with it.

It was while the growers were in the flood-tide of this prosperity that the Lord Proprietor, looking ahead, recommended the Scillonians to turn part of their attention to the cultivation of the flowers which grew on the islands for Covent Garden Market. The majority were disinclined to give up Potatoes for flowers in ever so small a degree; but one farmer thought over Mr. Smith's suggestion, and collected some of the flowers growing on his ground. He sent the little lot to London, on which he cleared 2s. 6d.; and this was the beginning of the floriculture in Scilly, which has now reached giant proportions.

Just about the time that the last report of these Islands was printed in the Journal the Scillonians were brought more into touch with the mainland by means of a steamer which was started to run between the Islands and Penzance, and by means of a telegraphic cable between the two. Thus the Potatoes found a quick market, and the growers were kept informed of current prices. For the first fruits of the Potato crop—generally in May—as much as 1s. 6d. a pound has been received. Gradually the inhabitants were encouraged and stimulated to grow various new vegetables, and Asparagus, Seakale, Parsley, and Tomatoes were added to those sent to market.

The growers had their anxieties and troubles then even as now. The exposed situation of the Islands, and the lack of woods and trees to provide natural protection to their fields from the biting winds and heavy gales which sweep over the land, gave them many a night in "the open," keeping up fires round the fields to preserve the budding Potatoes.

It was this need of protection to their plants which caused them to supersede the loose stone divisions of land by planting Laurel, Escallonia, and other picturesque shrubs for hedges. This planting of hedges was, indeed, the foundation and preparation of the new development in the farming of the Islands. To-day the land is no longer given up solely to the growing of Potatoes, Parsley, Asparagus, and Seakale, for a large proportion is devoted to floriculture—a combination which has answered well in every way. The result may be seen in the absence of poverty, in the quiet unobtrusive independence of the people, in the improved outhouses on the farms, and in the possession of better farming implements. The people are neither so rich nor so poor as they have been (it was a proverb, "Either a feast or a famine in Scilly"), their life is freer of excitement than it used to be, and they seem to have fallen into the happy medium of comfort and content.

Last season the following supplies were sent from the Islands to the various markets on the mainland by the steamer plying between Scilly and Penzance:—

46,000 pads of fish (a pad is 50).
200 tons of flowers.
800 tons of Potatoes + 230 tons sent by boats and smacks.
150 tons of other vegetables.
3 tons of Seakale, from St. Mary's alone.
5 tons of Tomatoes.

The expense of carriage is 11s. per cwt. to Scotland, and 7s. 6d. to Covent Garden. The salesman's charge is 10 per cent, if he supplies boxes, and 7½ if he does not.

It would be difficult to find land anywhere so bursting with life and growth as that of the Scilly Islands; and were it not for the occasional want of rain, and the too great prevalence of gales, there would be no limit to its productiveness. The temperature is never intensely hot in summer, nor intensely cold in winter.

The soil of the Islands is composed mostly of decomposed granite and peat; here and there it is as black as soot. The very rich land seems to run in veins, while other has good rich soil for some distance down, till it touches the cold white clay. The soil is very loose, and drinks greedily every drop of rain. It will not refuse "a shower every day, and two on Sundays." The rainfall is quite different here from the mainland. The average in Middlesex is 24 inches, in Scilly 31 inches, and in Cornwall it is 44 inches. Scilly would be glad of an inch a week. The soil, good as it is, lacks phosphate of lime and ammonia,

both of which can, fortunately, be supplied in a great measure by the seaweed manure.

The method here of making seaweed manure is to make a bottom or foundation of earth. On this the seaweed is spread, and covered with a layer of sand. After a month or two the juices have penetrated the earth, which is then ready to be carted away, and laid on the soil. The people use a peculiar-looking instrument for cutting through the seaweed manure. It has a blade 8 inches long and 7 inches wide. If the seaweed be driven in when Potatoes are to be planted it is put straight on the earth, and often worked in by the plough, and the Potatoes planted in at once. Then the soil and seaweed mixed are turned over on the Potatoes. Potatoes planted in fresh seaweed are waxy. In Scilly the Potatoes are planted much nearer the surface than on the mainland. If they were so planted on the "main" they would be destroyed by frost.

Out of the 3560 acres—which are the figures of the last Government survey—2242 are tillable or improvable.

Every farmer is more or less a flower farmer, but the larger ones grow also Potatoes, Seakale, Asparagus, and Tomatoes for the markets, as well as flowers. They keep a small number of cattle and sheep and grow corn, but only sufficient for home use. They make their own butter and keep poultry. But of all these last nothing is exported—they have sufficient only for home consumption. The butter is exquisite, and would be gladly bought on the mainland if it could be spared; and the same may be said of the fruit, which is grown principally at Rocky Hill and Holy Vale. It is excellent, but only sufficient for home use, and, moreover, the Apples are too mellow to bear packing.

St. Mary's has an area of 1527 acres, most of which is under cultivation. The largest farmer owns 70 acres of cultivated land. Eight of these are devoted to flowers and 10 to Potatoes. He grows no other vegetable but a large quantity of Mangels. He owns twenty-eight head of cattle, three horses, and fourteen sheep.

The cultivation of flowers has not reduced the amount of Potatoes grown so much as one might think, and for this reason—every foot of land formerly waste capable of cultivation is laid under tribute for the flowers.

An average-sized farm is held by a gentleman who farms 36 acres of tilled land, and 105 acres of common or waste land. Four or 5 acres are planted with flowers, and about 7 with Potatoes. He has twenty horned cattle and twenty sheep. He grows enough corn to feed the cattle, and the grazing ground is contained in the 36 acres. Seaweed is, he considers, by far the best manure for Asparagus. Tomatoes have so gone down in price that 9d. per pound is the price during December, January, and February. In planting he would use about 25 cwt. of seed Potatoes to an acre, and he would consider between 4 and 5 tons an acre a good return. His preparation of the ground for receiving Potatoes is to well press it and plough it, and dress it twice with seaweed and compost, the latter consisting of road scrapings, earth, and "anything good." It is then ploughed down, scarified with a cultivator, and left to rest. Sometimes artificial manure is given, and a small quantity of guano is imported. On the waste lands an immense quantity of Ferns grow, which, being cut, make excellent beds for the cattle, and when they have served this purpose they form a capital manure. May and June are the great months for sending Potatoes to market, though, owing to the mildness of the winter, Potatoes planted in December are often drawn again in March, when there is a good sale for them. After Potatoes he gets a fine crop of Mangel.

Seakale is largely grown on the Islands, and sent to the London, Birmingham, and Manchester markets. It is grown in the open air, and blanched in the same way as Celery, with the exception that it is planted on the surface instead of in the trenches. Seakale would be by far the most remunerative crop, and if only they could ensure 3d. or 4d. a pound for it the Scillonians would go into its cultivation very largely. It requires no manure, but wants a light soil. At Tresco a great quantity is grown. The cost per acre is £30 or £40, the return £70 or £80.

The island of Tresco, though only twenty minutes' distance by boat (in fine weather), is much warmer than St. Mary's, because of the sand all round it. Mr. Dorrien Smith's farm at Tresco is essentially a model farm. He spares neither expense nor trouble, and when a successful result is attained he shares it with his tenants. He uses about 30 tons of seed Potatoes for planting. Twenty-five to 30 acres are planted with Potatoes. Where possible they are planted on slopes, so as to escape the wind, and the order of planting is "six rows, one miss." The "miss" is well manured, and later on is turned up and spread over the six rows. Three tons of Seakale and 5 tons of Tomatoes were sent from here last year. From 17 to 20 acres are devoted to flowers. Mr. Smith is experimenting upon a parcel of land, dividing it into four, dressing one part with fish manure, one with farmyard manure, the third with seaweed, and leaving the fourth unmanured. He has twenty Channel Islands cattle and about 100 pigs. The food for the last is cut up, and cooked in a large boiler. The dried Fern makes good litter for pigs and cattle.

All sorts of fences are tried on this farm for the protection of flowers and vegetables. The rush fences are too opaque. The shrubs require great attention, and occupy valuable space; but the open palings of wood protect, while they permit the sun to play through.

Of all the islands St. Martin's produces the most Potatoes, while some of the earliest come from Bryher.—E. BREWER (*Journal of the Royal Agricultural Society*.)

NATIONAL AURICULA SOCIETY.

NORTHERN DIVISION.

THE Exhibition of the Northern Section of this was held on April 29th in the New Town Hall, Manchester. It was a full and brilliant Show, with many fine examples of all the classes of the florist's Auricula. The competition was keen, and the competitors included some fresh growers, always a feature of interest and of promise for the future. Considering the coldness of April and its east winds there were many more flowers exhibited than were expected, and all the classes were well filled.

The following is the complete list of the prizewinners, with names of the winning flowers:—

Six Auriculas, dissimilar.—First, Rev. F. D. Horner, Burton-in-Lonsdale, with Magpie (Horner), Miranda (Horner), Rev. F. D. Horner (Simonite), Monarch (Horner), Mrs. A. Potts (Barlow), G. Lightbody (Headly). Second, Mr. T. Lord, Todmorden, with Rev. F. D. Horner (Simonite), G. Lightbody, R. Headly (Lightbody), Acme (Read), Mrs. A. Potts, Brunette (Pohlman). Third, Mrs. Kyrke Penson, Ludlow, with Prince of Greens (Traill), G. Lightbody, John Simonite (Walker), Heather Bell (Simonite), Mrs. Dodwell (Woodhead), Prudence (Kyrke Penson). Fourth, Mr. B. Simonite, Sheffield, with Heatherbell, Heroine (Horner), Dr. Hardy (Simonite), Mr. Hannaford (Simonite), and two seedlings unnamed. Fifth, Miss Woodhead, Hipperholme, Halifax, with Mrs. Dodswell, Acme, Black Bess (Woodhead), Prince of Greens, Talisman (Simonite), G. Rudd (Woodhead). Sixth, Mr. Jos. Butterworth, with Lancashire Hero (Lancashire), Ellen Lancaster (Pohlman), Acme, A. Meiklejohn (Kay), Chas. Perry (Turner), Lovely Ann (Oliver). Seventh, Mr. Henry Wilson, Halifax, with Prince of Greens, G. Rudd, Lancashire Hero, John Simonite, Mr. A. Potts, G. Lightbody.

Four Auriculas, dissimilar.—First, Rev. F. D. Horner, with Magpie, G. Lightbody, Rev. F. D. Horner, Mrs. A. Potts. Second, Mrs. Irving Hind, Halifax, with Acme, A. Meiklejohn, Chas. Perry, Mayflower (Traill). Third, Mr. T. Lord, with G. Lightbody, Brunette, Mrs. Dodwell, Rev. F. D. Horner. Fourth, Mr. Hy. Wilson, with G. Lightbody, John Simonite, Mrs. A. Potts, Prince of Greens. Fifth, Miss Woodhead, with Acme, Black Bess, Rachael (Woodhead), Imperator (Litton). Sixth, Mr. W. Taylor, Middleton, with Acme, A. Meiklejohn, Chas. Perry, Mayflower. Seventh, Mrs. Kyrke Penson, with G. Lightbody, John Simonite, Rev. F. D. Horner, Negro (Mellor).

Two Auriculas, dissimilar.—First, Mr. E. Shepley, Middleton, with A. Meiklejohn and Mayflower. Second, Mr. Geo. Middleton, Prestwick, with Beauty (Traill) and Mrs. A. Potts. Third, Mr. E. Shaw, Moston, with A. Meiklejohn and a seedling. Fourth, Mr. J. Beswick, Middleton, with Dr. Horner (Rudd) and Lovely Ann.

Auriculas, pairs for maiden growers.—First, Mr. Jas. Wood, with Prince of Greens and Frank Simonite (Simonite). Second, Mr. Irving Hind, with John Simonite and Lancashire Hero. Third, Mr. E. Walker, Leek, with G. Lightbody and Negro. Fourth, Mr. G. Thornley, with Chas. Perry and Traill's Beauty.

Premier Auricula of the Exhibition.—Rev. F. D. Horner, with Magpie (Horner), white-edged.

Single plants, green-edged.—Premium, Mr. B. Simonite, with Mr. Hannaford. First, Rev. F. D. Horner, with Attraction (Horner). Second, Rev. F. D. Horner, with Monarch. Third, Mr. B. Simonite, with Thalia (Simonite). Fourth, Rev. F. D. Horner, with Rev. F. D. Horner. Fifth, Mr. B. Simonite, with seedling. Sixth, Mrs. Kyrke Penson, with Col. Taylor (Leigh). Seventh, Mr. Hy. Wilson, with Prince of Greens. Eighth, Mr. W. Taylor, with Talisman.

Grey edged.—Premium, Mr. T. Lord, with G. Lightbody. First, Mr. T. Lord, with G. Lightbody. Second, Mr. J. Butterworth, with A. Meiklejohn. Third, Mrs. Kyrke Penson, with seedling. Fourth, Mr. B. Simonite, with Agamemnon (Horner). Fifth, Miss Woodhead, with Rachel. Sixth, Miss Woodhead, with G. Rudd. Seventh, Mr. E. Shepley, with Lancashire Hero. Eighth, Mr. W. Barnfather Leek, with Dr. Horner.

White edged.—Premium, Rev. F. D. Horner, with Magpie. First, Mr. E. Shepley, with Acme. Second, Mr. T. Lord, with John Simonite. Third, Rev. F. D. Horner, with Magpie. Fourth, Mr. E. Shaw, with True Briton. Fifth, Rev. F. D. Horner, with Reliance (Mellor). Sixth, Mrs. Kyrke Penson, with Dr. Kidd (Douglas). Seventh, Mr. W. Taylor, with Beauty (Traill's). Eighth, Mr. Hy. Wilson, with Mrs. Dodwell.

Selfs.—Premium, Rev. F. D. Horner, with Laura (Horner). First, Rev. F. D. Horner, with Dimple (Horner). Second, Rev. F. D. Horner, with Lælia (Horner). Third, Rev. F. D. Horner, with Lynette (Horner). Fourth, Mr. B. Simonite, with Heroine (Horner). Fifth, Rev. F. D. Horner, with Scarlet Gem (Horner). Sixth, Mrs. Kyrke Penson, with Prudence (Kyrke Penson). Seventh, Mr. E. Shaw, with seedling. Eighth, Mr. T. Lord, with Black Bess.

Alpines, shaded, four dissimilar.—First, Mr. J. Beswick, Middleton, with Emin and three seedlings. Second, Mr. H. Geggie, Bury, with Diadem and three seedlings. Third, Mr. J. Butterworth, with Victoria, Diadem, Almyra, and seedling. Fourth, Mr. E. Shaw, with Victoria, Mrs. Ball, Diadem, and Terminal. Fifth, S. Barlow, Esq., Stakehill, with Diadem, Prior, Mrs. Llewelyn, and seedling. Sixth, Mr. Wm. Taylor, with Diadem, Mrs. Dodwell, Nimrod, and John Leech. Seventh, Mr. T. Stelfox, Stalybridge, with Victoria, Mrs. Dodwell, Racer, and seedling.

Single plants (yellow centre).—Premium, Mr. J. Clements Harborne, with Unique. First, Mr. J. Clements Harborne, with Mrs. Ball. Second,

S. Barlow, Esq., with seedling. Third, Mr. J. Butterworth, with Unique. Fourth, Mr. Beswick. Fifth, S. Barlow, Esq., with Mr. Llewelyn. (White centre).—Premium, Mr. J. Beswick, with seedling. First, Mr. J. Beswick, with seedling. Second, Mr. J. Butterworth, Victoria. Third, Mr. J. Beswick, seedling. Fourth, Mr. J. Clements, Minnie Turner. Fifth, Mr. J. Beswick, seedling.

Polyanthus, black grounds, three dissimilar.—First, Mr. Jos. Butterworth, with Cheshire Favourite, Exile, and seedling. Second, Mr. J. Beswick, with Cheshire Favourite, Lancashire Hero, and Exile. Third, Mr. A. Oldham, Middleton, with three seedlings. Fourth, Mr. G. Thornley, with Prince Regent, Exile, and Cheshire Favourite. Fifth, Wm. Brocklebank, Esq., Didsbury, with Black Cap, Black Knight, and Jubilee. Sixth, S. Barlow, Esq., with Cheshire Favourite, Exile, and John Bright.

Polyanthus, red grounds, three dissimilar.—First, Mr. J. Butterworth, with George IV., Prince Regent, and seedling. Second, Mr. G. Thornley, with Lancer, George IV., and seedling. Third, Wm. Brocklebank, Esq., with Ensign, George IV., and Regina. Fourth, Mr. W. Taylor, with Lancer, Prince Regent, and George IV. Fifth, Mr. J. Beswick, with Lancer, seedling, and Prince Regent.

Polyanthus, light plants, black grounds.—Premium, Mr. J. Butterworth, with Exile. First, Wm. Brockbank, Esq., with Black Knight. Second, Mr. A. Oldham, with seedling. Third, Mr. J. Butterworth, with Cheshire Favourite. Fourth, Wm. Brockbank, Esq., with Jubilee. Fifth, Mr. G. Thornley, with Exile. Sixth, Mr. A. Oldham, with seedling. Seventh, Mr. A. Oldham, with seedling.

Polyanthus, single plants, red grounds.—Premium, Mr. J. Butterworth, with George IV. First, Mr. J. Butterworth, with George IV. Second, Mr. J. Butterworth, with Prince Regent. Third, Mr. A. Oldham, with seedling. Fourth, Mr. J. Butterworth, with Lancer. Fifth, S. Barlow, Esq., with Sydney Smith. Sixth, Mr. G. Thornley, with seedling.

Twelve fancy Auriculas.—First, S. Barlow, Esq. Twelve fancy Polyanthus.—First, S. Barlow, Esq. Twelve fancy Auriculas.—First, S. Barlow, Esq.

FRUIT FORCING.

VINES.—*Early Houses*.—Red spider is the bane of early forcing. It is hardly possible to escape visitation by this pest, therefore where it has obtained a footing prompt measures must be adopted for its destruction. Syringing is perhaps most effectual, as water is the great cleanser of plants, but its application to Grapes after they are advanced in colouring is dangerous, as the water, no matter how clear, is liable to leave a deposit upon the berries. Sponging the leaves, though an excellent mode of preventing the spread of the pest, and if taken in time an effectual one, yet is in most cases resorted to so late as to render it but a partial remedy by a tedious operation. The application of sulphur to the pipes in a judicious manner is the most effectual preventive. Flowers of sulphur mixed with skim milk to the consistency of cream and applied with a brush to the pipes when heated to between 180° to 200°, maintaining the pipes at the temperature indicated for an hour, and then the heat allowed to fall to the ordinary temperature, will kill all the pests existing, but it may be necessary to repeat it at intervals of a week or ten days in order to destroy those emerging from the eggs. Choose a calm evening, and in bad cases repeat the process. Take care not to overheat the pipes nor to give an overdose, or the skins of such varieties as Frontignans and Muscats will be seriously affected, especially those but partially ripened. Where fermenting materials and judicious ammoniacal vapour employed during growth red spider does not prove very troublesome. Fermenting material on outside borders will have become heavy and cold; a portion should be removed, leaving sufficient to avoid giving a sudden check. Early Grapes that are ripe will only require enough fire heat to maintain a circulation of dry air, allowing the temperature to fall to 60° at night.

Vines Started at the New Year.—The Grapes are commencing to colour. Inside borders must have due supplies of water or liquid manure in a tepid state, the quantity being such as to thoroughly moisten the borders to their depth and give a mulch of short material, but no great means should as yet be employed to produce a dry condition of the atmosphere, as the Grapes will swell considerably in ripening. A good moisture must be maintained in the early stages of ripening, sprinkling the house in the early part of the day and at closing time, a little ventilation being provided constantly to induce a change of air and prevent the deposition of moisture on the berries. A warm genial condition of the atmosphere with a circulation of air is essential to insuring thoroughly swelled berries. Maintain the temperature at 70° to 75° by day from artificial means, and 80° to 85° through the day from sun heat, advancing in the early afternoon to 90° or 95°, falling with the declining sun or light to a night temperature of 60° to 65°, 5° more by day and night being necessary for Muscats. As the fruit

advances in colouring the moisture should be gradually reduced and the ventilation increased, but there must not be any diminution of the temperature until the Grapes are fully ripe. Grapes that are liable to crack, such as Madresfield Court, may, when ripening commences, have the needful supplies of water or liquid manure, and then have the inside border mulched with 4 to 6 inches thickness of dry material, which with early ventilation insures this remarkably fine Grape arriving at perfection.

Succession Houses.—Thinning, disbudding, stopping, and tying must be attended to as occasion requires, proceeding on lines indicated in former calendars. Especially let all superfluous bunches be removed as soon as the number to be left on a Vine is decided. Examine the borders of all succession houses at least once a week, and when dry supply water freely. Inside borders will take almost any quantity of water after the Vines are in full foliage, and with a full crop of Grapes liquid manure should be applied at every alternate watering. Outside borders will not as yet require water.

Late Houses.—Late Vines progressing rapidly must be tied and stopped as soon as they have made sufficient growth to cover the trellis with foliage. Admit air freely on all favourable occasions, as there is the greatest benefit in well developed foliage, stout and firm in texture, as upon these and their continuance in health depends entirely the swelling and maturing of the crop, particularly the finishing or colouring process. Every advantage, therefore, should be taken of sun heat to increase the ventilation early in the day, but close early, excessive fire heat being injurious; avoid a vitiated atmosphere.

Newly Planted Vines.—With advancing growth, an evidence that the roots are active, close attention will need to be given to the roots to see that they do not suffer from over-dryness. Allow all the wood to remain that can be exposed to light, but supernumeraries intended for fruiting next year should be confined to one rod or cane, and the laterals pinched at the first joint, stopping the cane when it has made about 8 feet of growth.

Vines in Greenhouses and Unheated Houses.—With rapid progress as the Vines are now making the growths will require disbudding, stopping, and tying. One shoot is sufficient to each spur unless they are wide apart, when two may be left, but there must be scrupulous attention to prevent overcrowding; every leaf must have exposure to light and air. Reserve those that show the best bunches, rubbing the others off. Stop two joints beyond the bunch; but rather than crowd the foliage stop one joint beyond the bunch, or even level with it. Tie down the shoots carefully and gradually. Old Vines sometimes do not fruit freely on spurs, being weak. It is best to lay in shoots from the base and along the rods at intervals of 2 to 3 feet, which will increase root action, the Vines attaining increased vigour, and longer pruning will usually afford better crops of Grapes; indeed, old Vines with fresh canes bear excellently. Apply a dressing of artificial manure to the border, a couple of ounces per square yard, and point it in very lightly. Inside borders may be given water or liquid manure, when dry a thorough soaking, and a mulching of short rather fresh manure will, by keeping the surface moist, encourage active roots.

MELONS.—**Early Plants.**—Directly the fruit begins ripening lessen the supply of water at the roots, but not so as to distress the plants, for if the foliage has been kept clean and the roots in good condition a second crop of fruit may be had. Atmospheric moisture should be withheld, and a circulation of dry air ensured, increasing the temperature to 70° or 75° artificially, and 80° to 90° with sun heat. Cut the fruits before they are very ripe, keeping them in a fruit room for two or three days, or until they are in proper condition to be sent to the table. Cracked fruits are produced by a close and moist atmosphere, with too much moisture at the roots, which induces an excess of sap. If any fruits show a tendency to crack cut the shoots about halfway through with a knife a few inches below the fruit, and diminish the supply of water at the roots and in the atmosphere, leaving a little ventilation constantly to prevent moisture condensing on the fruit.

Successional Plants.—Continue to fertilise the flowers when fully expanded, the atmosphere being kept rather drier and warmer, and ventilation attended to early, with a little constantly if there is danger of moisture condensing on the blossoms. Stop the shoots one or two joints beyond the fruit at the time the fertilisation is done. To secure a full crop take care to have a number of fruits on individual plants in the same stage of growth. Earth up the plants with some rather strong and rich loam after the fruits begin to swell, ramming it down firmly, placing a little fresh lime around the collar to prevent canker. Plants swelling their fruits should be syringed freely in hot weather about 3 P.M., damping the floor several times a day, and in the evening sprinkle available surfaces with liquid manure or guano water, 1 lb. dissolved in 20 gallons. Shade only to prevent flagging. Ventilate freely in favourable weather, commencing from 75° to 80°, increasing or decreasing it through the day as may be necessary, maintaining a day temperature of 80° to 85°, or 90° with sun heat, closing between 80° and 85°, and if an advance is after closing made to 90° or 95° it will materially assist the fruit in swelling and lessen the necessity for fire heat at night, but it must be accompanied by plenty of atmospheric moisture. If thrips appear fumigate on two or three consecutive evenings, taking care to have the foliage dry, and for red spider dress the hot-water pipes with flowers of sulphur.

Train out the growths in pits and frames. Still maintain a good bottom heat by linings, and employ thick night coverings, as the nights are yet cold. Sow seed for raising plants to put out in pits and frames

as they become cleared of bedding plants, early Potatoes, &c., potting the young plants as required.

Tomatoes in Houses after Bedding Plants.—Structures that are light and airy may be profitably utilised for these plants. They do well in 10-inch pots, a single plant in each. Drain the pots efficiently, place a layer of rough pieces of turf over the crocks, and then turn out the plants, using turfy loam with about a fourth of well decomposed manure. A considerable space should be left in the pot for fresh compost, additions being made as the plants advance in growth, and feeding with liquid manure will secure an abundant crop of fruit. Train the plants as single condons to wires 9 inches from the glass, removing all laterals or side shoots, but being careful to preserve a leader. The plants will have fruit from the first show at about every second joint, and the lead should not be stopped unless the limit of the trellis is reached, then remove growth as it appears. Shorten the leaves about a third of their length. The plants may be 12 to 18 inches apart. Keep the house rather close until the plants are established. Ventilate a little at 65°, increase it at 75°, and above that ventilate freely. Close early, so as to run up to 80° or 85°, which will enable the grower to dispense with fire heat after the middle of the month.

PLANT HOUSES.

Epacris—Plants that flowered early may be repotted if they need more root room. Drain the pots carefully, and the soil must consist of good peat and sand. Do not disturb the old roots further than is necessary in removing the drainage. In potting press the soil firm, and be careful not to bury the collar of the plant lower than usual. If the plants have been carefully hardened they may be placed at once in cold frames. For the first ten days or a fortnight keep the frames close, and dew the plants with the syringe once or twice on fine days. Close the frame early in the afternoon. The plants must be watered carefully for some time after they are repotted. Later plants may be kept close, and syringed freely until they start into growth. A close moist atmosphere is beneficial at first, but as soon as they are well started air must be gradually admitted.

Erica hyemalis.—Plants that have commenced active growth may be placed in cold frames. Be careful not to crowd them, or the lower foliage will turn brown and eventually fall. If the plants need repotting do it at once. Peat and sand should be used for a compost, and pressed firmly round the balls, which should not be disturbed beyond the removal of the drainage. Keep the frames the same as advised for Epacris, and then admit air carefully at first, and increase it until liberal ventilation can be given. A firm sturdy growth should be aimed at if the plants are to flower freely.

Erica gracilis.—This Heath is very liable to mildew if the plants are subjected to a close confined atmosphere. Directly any trace is observed dew them with the syringe and dust the affected parts with powdered sulphur. These plants may be potted the same as advised for E. hyemalis, but the smallest possible shift should be given. Do not attempt to keep these close after potting, but place them in frame and admit air abundantly.

Cytisus racemosus.—Plants that have flowered may be well pruned and placed in the greenhouse until they start again into growth. They may be syringed once or twice daily, and repotted if they need it. Young bushy specimens in small pots may be transferred into 5-inch pots, a suitable size for decorative purposes. Young plants that are still in store pots may be potted singly into 2-inch size. Grow these cool, and pinch their shoots from time to time as they need it. Small standards with stems 18 inches high are very effective; these can be run up until the desired length has been attained before pinching is practised. They do well in a compost of good loam, one-seventh of decayed manure and sand. A little leaf soil may be used with advantage for those placed in their first pots.

THE BEE-KEEPER.

NOTES ON BEES.

THE WEATHER.

THE cold wintry weather which prevailed from the 7th to 29th April has given way to lovely summer-like weather, a pleasant change for everything depending upon it, the mean temperature rising from 36½ to 60° Fahr. The mildness induced me to take a ramble amongst fruit growers and bee-keepers. Notwithstanding the severity and ungenial weather in April there is no reason to suspect any damage to the fruit blossom.

Bees had a severe trial, and many were lost the last week of the three, and I learned that many weakish hives succumbed which but for the ungenial weather would have done well. After breeding commences briskly bees cannot defend themselves against a spell of cold so well as they can do before breeding against a zero temperature. The moral is obvious. Keep your hives protected so that they are little affected internally by extremes in tempera-

ture, and never alter the doorway until the bees show signs of performing this themselves. Let Nature take her proper course, and the bee-keeper provide in September all that is necessary to tide the bees over till May, and by that time nothing will be required to be done except to hive swarms. My visit to these apiaries was on the 1st of May, and many hives were crowding out, and with favourable weather swarming cannot be many days delayed. All districts may not be so early, but the same course of management applies to all.

ABSCONDING SWARMS.

As is usually the case these have been prevalent this spring. I have had a number of queens of these "fly aways" sent me, and in every case, as I have previously found, the queen was defective. I believe that cold has to do with this, and the term "hunger swarm" is an improper one.

QUEENLESS HIVES.

These appear to be numerous, and this defective state of matters is, in most cases, entirely due to the bee-keepers themselves by joining swarms without proper precautions to protect the best queens from harm, or carelessness in their manipulations, allowing stranger bees to enter. Virgin queens are also present from the same or similar causes, being raised at an improper season, and inaccurate instructions may fertile workers and imperfect queens be traced. Bee-keeping instructions, like other rural occupations, have been largely given by inexperienced persons from the writings of others, much to the discredit of themselves and to the loss of the unsuspecting novice. The wholesale plagiarism noticed lately is good proof of this. I send you by same post as this a journal containing an article of mine with *nom de plume* attached, but I think it scarcely fair to copy so largely without giving the source whence it was obtained.* An amusing case of plagiarism occurred some time since. An American paper published an article of mine, a person I had to call to order for his mis-statements copied it, and it appeared in the *Farming World* as original.

FOREIGN RACES OF BEES.

The Punic bees are still giving satisfaction, but are not yet far enough advanced to be put to a proper test. The Cyprian crosses that have given a large surplus of honey every year for thirteen years, and that without feeding, are storing honey more rapidly than any other variety. Carniolians are strong, and they, with the crossed Syrians, are ready for swarming. I saw lately a swarm of pure Ligurians supplied by Messrs. G. Neighbour & Sons, which for a time were rare, owing to the stupidity of certain individuals setting forth that beauty and industry went together, and encouraged the importation of Ligurians crossed with Cyprian or Syrian blood. We trust this practice has ceased. The foregoing hints will perhaps assist the bee-keeping readers. A future article will further enable them how to prepare for the Heather harvest.—A LANARKSHIRE BEE-KEEPER.

BEES IN THE NORTH.

THE prospect as regards East Yorkshire is cheering. The warm weather, with the Willow and Peach flowers, have rendered the bees busy. The Pears and Apples have also helped; the Thorns and Sycamore promise well. All we want is warm sunny weather, and our hives being strong the honey harvest of 1890 is assured. Spring dwindling is unknown to me this year. I went to winter quarters with twenty hives; these are all alive and doing well, and vigorous queens are filling the vacant cells with eggs. "A L. B. K." speaks of supering in the third and fourth week of June (page 329), but I like my bees to be ready for supers by the 12th of May, or before that date if possible. If I deferred supering until the third week of June the honey harvest would be nearly over. As before, I shall work my bees on the non-swarming system, as it suits me best, and with young queens, large hives, plenty of room at the right time, the swarming fever is reduced to a minimum. The non-swarming system I would recommend where the honey flow is of short duration and the bee-keeper's time limited. On the other hand, where the honey season is of longer duration the swarming system answers well. The honey season is over here by the 12th of July or nearly so. The non-swarming system has failed with some. Why? Simply because the requirements of the bees were not met at the proper time. I have worked my bees on the non-swarming system for some time, and have no cause for regret, and I know others that have done the same. This is scouted by some able bee-keepers, but facts and experience teach me in most cases swarming may be prevented, allowing an exception to every rule. However, such has been the experience of—A HOWDENSHERE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

B. S. Williams & Son, Victoria and Paradise Nursery, Upper Holloway, London, N.—*New and General Plant Catalogue, 1890 (illustrated).*

Thomas S. Ware, Hale Farm Nurseries, Tottenham, London.—*Catalogue of Choice Dahlias.*

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and these on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Garden Hose (W. G.).—Hose that is advertised periodically in the *Journal of Horticulture* is exactly suited to your requirements, and all particulars relating to size and price can be obtained from the vendors. The hose must either be attached to a pipe containing a good pressure of water, or to a pump for forcing the water to where it may be required.

Garden Plans (G. M.).—We are unable to say from whom you can get plans such as you need, and there is no work that contains plans suitable to all positions. For laying out a garden properly it is requisite that the site be carefully inspected by a competent person, who can furnish plans showing how the ground can be laid out to the best advantage. There are gentlemen's gardeners in your district who can no doubt prepare plans of gardens.

Peas for Preserving (M. G.).—If we understand your requirements they would have been best met by sowing such a variety as Dillistone's Prolific three months ago. You may or may not obtain a good crop by sowing now, according as the soil and weather may be favourable or otherwise for free growth. A good dwarf-growing, round, green seeded main crop Pea is Pride of the Market. The Peas are a little larger, though sweeter, than the small earlier white round-seeded varieties.

Figs Falling (Fig).—We have no doubt the excessive vigour of the tree is the chief, if not the sole cause of the dropping of the fruit. The border is too rich, and possibly may be deficient in calcareous matter. Much firmer soil with more restricted root action is essential in your case, and only with the leaves fully exposed to the direct action of the sun could the trees be fruit sustaining. We should lift them in the autumn, and add a sixth part of lime rubbish to the soil, making the border as firm as possible. If the soil is deficient in lime, some lime water given at once might act beneficially.

Mildew on Vines (Wet Border).—An excessively wet border would predispose the Vines to attack, inasmuch as the root action could not be free and healthy; the leaf action would then be correspondingly impaired and the sap imperfectly elaborated. Leaf action is similarly impaired by a too close and moist atmosphere, also by sharp currents of air striking directly on the Vines. Any or all these impediments to free sap movement and purification render Vines and plants liable to fungoid attacks, inasmuch as the conditions are favourable to the vegetation of the spores of the parasite.

Bedding Pelargoniums (Oaks, Surrey).—"Autumn cuttings" of these plants cannot be had now. They are plentiful early in August, and that is a good time for inserting them. Vesuvius is a favourite compact growing scarlet variety. John Gibbons is suitable for large beds, and Henry Jacoby, rich crimson, is highly effective and floriferous. Plants from autumn struck cuttings, established in pots, and ready for planting out as soon as the weather is safe, are provided by most nurserymen and florists in the metropolitan district. It is contrary to our rules to recommend any particular dealer, as we could not do this without being unfair to the majority not mentioned.

Marechal Niel Rose (W. S.).—The sooner the pruning is done the better, and the warmer and closer the plant is kept, consistently

* It is most unfair. The paper referred to is published in Edinburgh, and we are surprised that any proprietor of good standing should countenance such practice.—ED.

with the requirements of other plants in the house, the better. Give a liberal supply of very warm water as often as the soil gets somewhat dry; it must not be too wet when there are no leaves on the plant. Syringe once, twice, or thrice a day according to the weather. It will be advisable to let the soil get rather dry before the second pruning, and for a week afterwards, then proceed on the lines above indicated. As growths extend more water will be needed, and all the sun and air possible, while syringing must be reduced as the summer advances, and discontinued in early autumn for the ripening of the wood. Avoid overcrowding of the shoots and foliage, and prevent insect attacks.

Fungus on Gooseberries (*E. J.*).—The leaves and berries sent are seriously infested with the Gooseberry fungus (*Ecidium cancellatum*). Mr. John Graham, an experienced grower, cleansed his bushes by giving the ground a heavy dressing of lime, and syringing the bushes with the following mixture:—Alum, 1 drachm; tobacco essence, 2 drachms; flowers of sulphur, $\frac{1}{2}$ oz.; common salt, $\frac{3}{4}$ oz., in 3 gallons of rain water. This was done twice before the expanding of the leaf, and again as soon as the fruit appeared fairly set. The lime destroyed the mycelium in the soil, and the syringing cleared the bark of sporules, the result being clean bushes. You can try the same remedies now, but the attack being so virulent you may not effect a cure by one application, if in one season.

Apples and Pears for Light Loam over Chalk (*T. S.*).—Dessert Apples:—Irish Peach, Worcester Pearmain, King of the Pippins, Fearn Pippin, Claygate Pearmain, and Cockle Pippin. Kitchen:—Domino, Warner's King, Golden Noble, Annie Elizabeth, Bramley's Seedling, and New Northern Greening. Of dessert you may also try Cox's Orange Pippin and Golden Ducat; and of kitchen, Colonel Vaughan and Duck's Bill. Of Pears there is little prospect of a succession until May from standards, as the late varieties do not succeed as standards. Doyenné d'Ete, Jargonelle, Williams' Bon Chrétien, Beurré Superfin, Comte de Lamy, Louise Bonne of Jersey, Doyenné du Comice, Marie Louise, Passe Colmar, Knight's Monarch, Winter Nelis, and Bergamotte Esperen give a good succession. For stewing, Catillac, Verulam, and Vicar of Winkfield.

Thuia Lobbi for Screens (*G. H.*).—Without doubt this is one of the best Conifers for forming ornamental hedges and valuable sheltering screens, though it would be some time before getting tall enough for protecting standard orchard trees. It is very elegant in growth, and retains its bright green colour in winter. It grows freely in good loamy soil, such as is suitable for fruit trees. One row is sufficient for forming a good screen. We know of a number of trees that were planted 6 feet apart all grown together now forming a beautiful hedge 20 feet high and 8 feet through at the base. The distance for planting depends entirely on the size of the trees and whether a close hedge is desired at once. If a space be allowed between the trees equal to their diameter they will soon touch each other, and every alternate one can then be removed if desired to form another screen, or they can be left and trimmed to form a close hedge. You will find much of interest in respect to this fine North American tree in Veitch's "Manual of the Coniferae," in which it is illustrated. There is some confusion regarding its nomenclature. Its correct name is no doubt *Thuia gigantea*, but the Conifer widely known under this name is *Librocedrus decurrens*; but we think the Conifer you inquire about is sold as *Thuia Lobbi* by most nurserymen. It was introduced by Messrs. Veitch & Sons in 1853 through their collector, Mr. William Lobb, hence its name.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*A. F.*).—*Tritoma crocata*. (*K. E.*).—The specimens were much dried, and we can only guess that 1 is *Cassia corymbosa*, and 2 is *Corydalis lutea*. (*J. B.*).—It is apparently a form of *Cymbidium Parishii*. (*W. W., East Yorks.*).—*Laelia purpurata*. (*W., Reading*).—*Oncidium Marshallianum*. *Tecoma jasminoides* will succeed in a greenhouse, the others named require a stove. (*W. W.*).—*Acer saccharinum*. (*W. H. T.*).—The specimens are good examples of the Jack-a-napes *Polyanthus*. (*A. B., Lincoln*).—The Daffodil appears to be a form of the *N. Johnstoni* type. (*H. P.*).—The *Pelargonium* sport is well variegated, but it is doubtful if it would keep true.

Dimensions of Lanarkshire Hive (*S. R.*).—As you do not mention which Lanarkshire hive it is, we presume it is the L. D. one. The size of each division is 14 by 14 inside measure, and thickness of wood, five-eighths. This size should be strictly maintained, at least across the frames, nine filling up the space, $\frac{1}{4}$ inch centre to centre, the outside spaces for obvious reasons being a quarter of an inch wider. They are $6\frac{1}{2}$ deep over all, but that need not be maintained, but should not be less than 6 inches. The ends or uprights of the frames are three-quarters less, and there is no bottom rail where shallow divisions are used. Queens should be reared from a strong stock that has swarmed in the natural way, and at the proper season, during warm weather, when fertilisation will be effected in the most satisfactory manner.

COVENT GARDEN MARKET.—MAY 7TH.

Bedding Plants in variety, in boxes and pots.

YOUNG PASTURE.

YOUNG pasture of the second or third year must now in many instances cause some anxiety where it is seen to be so much thinner in plant and weaker in growth than it was in the first year. If it was sown in poor soil with a corn crop, without any special preparation of the soil, without manure (or if manure was used it was probably unsuitable), and has been grazed in the ordinary way from the outset, deterioration has set in, the sown Grasses are fast dying out, to be slowly replaced by natural Grasses, and the pastures are practically worthless. For such pasture in its third year there is nothing to be done beyond the usual process of regular manure dressings to encourage the growth of the natural Grasses, the herbage of which is so decidedly inferior to that of

the sown Grasses selected and mixed with so much care. It is at the beginning of the second season that remedial measures are possible, and if now the plant is seen to be less vigorous and thinner than it was last year careful sheep folding may do much to arrest and prevent further failure.

Small folds never left beyond the second day, and a liberal allowance of nourishing trough food, are the two most important points to observe. It is the turning in sheep to wander at will in new pasture that leads to such wholesale destruction of the young plant, for sheep have a decided preference for certain sorts of grass which they will feed off so closely and persistently as to kill it. Other grasses left untouched go to seed and die. All grasses do not fail after seeding, but some do, and the wisdom of prevention is obvious enough. No doubt many a puzzled farmer has asked himself why he has failed in laying down land to pasture, and we fear that in nine cases out of ten it is owing to mismanagement arising from ignorance of the few cultural points indispensable to success. It is not from mere prejudice that a tenant farmer almost invariably takes a corn crop with the pasture seeds, but rather because he considers he cannot afford to devote so many acres of land to pasture alone in the first year, and yet with good management a considerable amount of feed may be had from seeds the first season. To insure an end so desirable as this the land must have thorough autumn tillage, all perennial weeds then being got rid of, in doing which the soil is quite certain to be well broken up. After all we question if there is anything does this like a steam cultivator; only if we stir the soil too deeply and throw it up in huge clods the cleaning process is liable to be arrested if we depend upon autumn cultivation only, and therefore if the land is not available till after harvest, ploughing, followed by the duck-foot harrows, the roller, light harrows, and cross ploughing may be best. Every field must be treated according to its special requirements, and when the land is clean up with it at once into high ridges by means of the double-breasted plough, and so leave it till the following March. There it is, exposed as it can be by no other process of cultivation, to wind and weather—frost, snow, rain, and sunshine—in all the alternations of our changeable climate, so that when the sowing time comes it is so well pulverised as to insure us a fine deep tilth wherein shallow seeding and deep rooting are both admirably provided for.

Only get the land clean and ridged in autumn, and success is practically ensured; for is it not in our power to apply enough chemical manure to the soil to ensure fertility before sowing the seed? And even if we do take a thin corn crop with the seeds, can we not check the incipient exhaustion of the soil by the corn by another application of manure? Preferably we will avoid the corn crop, and do all that is possible to get in the seeds early, to prevent the annual weeds springing up among the Grasses and Clovers from producing any ripe seed. We will never turn in sheep or cattle upon young seeds to ramble and graze at will the first season, and if sheep go on at all it must be in folds; but the Rothamstead experiments have proved to demonstration how entirely possible it is to mow a new pasture from the first if only there is a regular and judicious use of manure.

WORK ON THE HOME FARM.

In our curtailment of the area of the Barley crop this season, not only was that devoted to Tartarian Oats largely increased, but also instead of drilling corn at all after the whole of the Turnip folds, much of it has been drilled with spring Tares and Oats both for silage and grazing, and that part of it reserved for Rape has just been sown. When the roots are so thin on the land that the sheep pass on quickly a little mineral superphosphate is used for the green crop, but this season the roots were a full crop; both sheep and lambs had too a liberal allowance of crushed corn and lamb food, so that the soil was thoroughly enriched, and no manure was required for the Rape. With deep, rich soil it answers best to drill Rape sufficiently wide to allow the horse hoe to be used, and to thin out the plant in the rows 9 or 10 inches apart. A crop of wonderful abundance is usually the result, and it comes into use in July just when feed is apt to run short on pastures.

Sheep continue so profitable that with the enlargement of the flock more land is taken for growing food of all kinds, and it was quite within the fitness of things that land on which sheep had been folded should be turned to account for a crop of early Turnips, which will come in for use when the sheep first go upon the stubbles after harvest. Sheep always thrive best when they have a frequent change of diet, and it is as unwise to keep them too long upon Rape or early Turnips as it is to suffer them to take fallen Barley ears too freely. Stubbles, pasture, Rape, Tares, Turnips all afford a wholesome change, and tend to promote health and condition. As the late summer folds are cleared of such crops the land is in admirable condition for ploughing for Wheat, for it is rich in fertility, and the sheep well repay us for the food they consume in this way. No autumn dressing of chemical manure is required, and it is most probable that the appearance of the corn in spring will be so satisfactory that we shall be content to let well alone, and to avoid any expenditure for manure then also. We have already seen lambs in considerable numbers offered for sale at market, and no wonder, for prices are very tempting to needy farmers.

CARTERS' NEW CROSS-BRED WHEATS.

MESSRS. JAMES CARTER & Co., the Queen's seedsmen, of 237 and 238, High Holborn, London, bring under public attention their new cross-bred Wheats—a feature of the Edinburgh Exhibition—which, from its practical importance to agriculturists, must arrest attention. These new Wheats, which have passed through one period of their existence on Messrs. Carter's seed farms at St. Osyth, first came under the eyes of the general public at the Paris Exhibition last year. Winning in 1882 the silver medal of the Royal Agricultural Society of England for the best variety of red seed Wheat, Messrs. Carter in the following autumn commenced experiments in the cross-breeding of Wheats, and for over six years have devoted unremitting care and attention to breeding, selection, and yearly re-selection, with the view of securing a thoroughly fixed character of the very best forms. The main objects sought for have been early maturity, quality of straw and grain, and vigour of constitution with increased productiveness. All these they claim to have obtained in a greater or less degree, and they urge that a trial of their new Wheats will prove greatly serviceable to all Wheat growers, as the blood of many of the most popular standard varieties runs in their veins. By observation during growth those selections can be determined for adoption and future cultivation that respond most liberally to the soil and surroundings, and by this means the most desirable varieties will be developed and reproduced. Mr. H. Evershed, in a late number of the *Journal of the R.A.S.E.*, summarises the experiments carried out by Messrs. Carter under his personal observation, and instances the varieties of the parents and the peculiarities of the offspring. It may be mentioned that length of straw is generally influenced by the male parent, and form and size of ear by the female. Mr. E. appends statistics showing the period at which twelve selections of cross-bred Wheats made their growth, together with comparative tables, giving the dates when "in ear" and when "ripe" in 1887 and 1888. These data sufficiently establish the systematic manner in which Messrs. Carter have conducted their experiments, and it cannot be doubted that the trials will have an historical bearing on the future life of the seed Wheat employed in British agriculture. Messrs. Carters' aim, as one of our great seed houses, has been that in view of keen foreign competition our indigenous grain may hold its own in the estimation of millers, and prove even more valuable for mixing with the hardest grains of India and America.

The French Government, desirous of recognising the service rendered to agriculture by the introduction of the cross-bred Wheats, have conferred upon the managing partner at Messrs. Carters' firm the high distinction of the Order du Mérite Agricole, this bestowal marking its first distribution in England.

REMARKS.

27th.—Fine on the whole, and frequently bright; but occasional spots of rain.
28th.—Heavy rain at 2 A.M.; fine day, with frequent sun, but spots of rain at midday.
29th.—Fine and bright.
30th.—Bright and mild.
1st.—Mild and almost cloudless; inner halo in evening.
2nd.—Fine but hazy at times, and cloudy about sunset; clear moonlight night.
3rd.—A little hazy, otherwise fine and bright.
A fine week; temperature just about the average.—G. J. SYMONS.

AMONG THE CATERPILLARS.

NOT a very attractive theme, will be the mental comment of some readers on first glancing at the above creepy-looking headline. It is certainly not pleasant to be crawled over by repulsive pests at any time, and it is distinctly the reverse of agreeable to see the enemies of plants and trees carry out a campaign of devastation. Yet this is what caterpillars have done and are doing in some fruit-growing districts, leaving behind them a scene of desolation dismal enough to engender feelings of despair in respect to the ultimate issue. Gardeners and others who are identified with fruit culture in localities which the winter moth has not yet invaded, have no idea of the destructive power of its larvæ, the caterpillars. It is the most insidious, persistent, voracious, and difficult to subdue of all the enemies that attack trees and plants. American blight, red spider, scale, Gooseberry caterpillars, and other familiar foes are troublesome enough where they abound, but the work of destroying them is considered as child's play in comparison with conquering the terrible pest under notice by persons who, day after day, and week after week, engage in the combat.

This is an old enemy in some districts, but until within recent years was more frequently seen stripping Hawthorn hedges and trees of their leaves, and huge Oaks of their foliage at midsummer, than as a visitant of gardens and orchards, but where it becomes established in these, and the season is favourable for its increase, it is bound sooner or later to ruin the trees. It is simply impossible if a number of winter moths deposit eggs on fruit trees in the autumn for any fruit to follow if the caterpillars are not promptly destroyed as they hatch out in spring. Nothing has been discovered that will destroy the eggs in winter without, at the same time, destroying those parts of the trees on which they are deposited. This has been proved by Mr. Lee Campbell at Glewston Court, Herefordshire. In the early part of the year his gardener sent some "prunings" from Pear trees to the *Journal of Horticulture* for showing the eggs of the moth *in situ* as they had been deposited by the moths two or three months previously. The parts chosen for nests were at the ends of stems that had been left after late summer or early autumn pruning. The wood in drying had shrunk sufficiently to leave small circular interstices between it and the bark, and in these minute chinks, only apparent on close examination, eggs were closely packed, and an example was shown (magnified) with some still much more enlarged on page 95, the issue of January 30th of the present year. This was something like a revelation, and at once accounted for the millions of caterpillars that come like a scourge with the bursting of the buds of the trees. Mr. Campbell has told us on page 333 that though sundry substances and liquids were tried for destroying the eggs, even vitriol, nothing was effectual. Since the publication of that article I have been to Glewston and seen there much that was admirable in fruit cultivation, much that was deplorable in the ravages of the caterpillars, much that was instructive in their methods of attack, and the measures that had been taken to destroy the eggs alluded to and the larvæ on emerging. A number of egg-holding stems were inserted in moist sand in a propagating pan, and all applications that were likely to destroy the eggs were tried. An enumeration is unnecessary, because when vitriol was used and killed the wood yet some of the

eggs hatched out, enough is said to show that they cannot be destroyed by anything that would not also injure the trees. Sealing the cut ends with lead paint answered the best, but as eggs are also deposited around the buds, and in slight depressions in the bark, the paint remedy is inapplicable, for to make sure of "sealing" all the eggs the trees would have to be painted all over, and there would be an end of them. The hatching process was expedited by placing the cuttings in heat, the experiments being immediately under the eye and conducted with the utmost possible care. They appear to have determined the fact that the eggs cannot be killed on the trees.

But having found the trees laden with eggs they were not allowed to remain, for we were told in the article referred to three men were employed for six weeks in cutting off the ends of the branches in which the eggs were so closely packed. These were burned, and though Mr. Campbell refrained from indicating the estimated number so disposed of lest he should have been thought to be making a sensational announcement, I am quite ready to believe, having seen examples, also inspected the re-pruned trees¹ that the eggs thus consumed must have amounted to several millions—a great riddance undoubtedly—yet, notwithstanding, if the work of extirpating the pest had ended there the trees would have been deprived of every vestige of blossom and leaf this season by the all-devouring caterpillars.

Fruit growers in localities from which this devastating pest is happily absent may almost be excused in suspecting, as some possibly do suspect, that its numbers, power of destruction, and the difficulty of mastering the nocturnal moth and larvæ, are exaggerated. It is simply impossible to exaggerate when the attack is virulent. Let me give an instance, and in a few words describe a scene that cannot readily be forgotten. It was in a southern county, not Herefordshire, and the month was June. There were acres of grand Oaks, and a considerable extent of old and new orchards; but neither on forest or fruit trees, or on Hawthorn hedges was a green leaf to be seen. The outlook was as dreary as at midwinter, and gates, fences, and road beneath the trees were covered with a writhing repulsive mass of caterpillars. In some places they were an inch thick, and caution was necessary in passing along to get a firm foothold amongst them. Exaggeration in such a case is out of the question, and I am fully convinced that fruit growers will err in lightly regarding the first mild attack of the enemy on their trees.

At Glewston Court some of the finest and best managed young trees in the kingdom were defoliated last year, and had not the autumn been fine, permitting a good second growth, something more than this year's crop would have been lost, for the trees must have been permanently weakened. The plantation consists of upwards of 6000 bush trees of Apples, Pears, and Plums, most of them planted six years ago. They have been admirably managed in every respect, and but for the caterpillars would now give a good return on the outlay that has been invested. This is proved by results, especially in an acre of Victoria Plums—680 trees at 8 feet apart. They are about 6 feet high, and there is only just room for passing between them. The ground is as clean as a garden, in fact the plantation represents first class garden culture. Planted in 1884 the Plum trees yielded in 1885 fruit to the value of £13; in 1886, £26; in 1887, £40; in 1888, £50. The last increase of £10 only was the result of the caterpillar seizure, and its effect on the trees was no fruit in 1889, while the leaves were devoured, consequently there will be little, if any, fruit to gather this year. Thus allowing for no progressive increase of crop since 1888 we find a loss by the scourge of £100 from this acre of Plums. To this has to be added the cost of spraying twice or thrice a week with Paris green. A Boulton and Paul barrel with pump and hose attached is used, and two men are always at work in the plantation, for though the caterpillars can be killed others are constantly hatching, and this has been the case since the last week in March

to the second week in May, and still they come. This prolongation of emergence is one of the most serious aspects of the visitation, necessitating, as it does, constant vigilance, anxiety, and action to subdue the ubiquitous enemy. The combat is very determined: the trees will be saved, perhaps some fruit on Apples and Pears secured, and success even to this extent will be richly deserved by Mr. Campbell and his watchful, industrious, and able gardener.

The fruit garden at Glewston is situated on a declivity above the beautiful valley of the Wye. The soil is a fertile sandy loam, quite light enough, yet splendid fruit is grown both outdoors and under glass, or chief prizes could not have been obtained for it at such shows as the Crystal Palace, Shrewsbury, Ledbury, Cheltenham, Ross, Monmouth, Manchester, and other places. Good glass structures have been erected near the Court. In a 120-foot range not many more fruitful Vines could be found, and their condition is largely attributed to applications of liquid manure in winter, when the soil is in a suitable condition for its reception. The value of this practice I discovered many years ago, and recorded the same in the *Journal of Horticulture* and subsequently. Some gardeners cannot understand how land charged with fertility in winter can benefit fruit and other crops in summer, and some writers who are not gardeners condemn the practice, which they have never tried. It is sound and good all the same when properly carried out, as it is at Glewston and in other gardens and orchards.

Long span-roof pits are devoted to Tomatoes, the plants being like trees, through being grown in firm shallow borders, abundance of air admitted, and a dry atmosphere maintained. There is more woody tissue in one of these plants than in a dozen of those which I have often seen fall a prey to disease. The Tomato disease is not in the least feared by the gardener at Glewston. He is of opinion that in by far the great majority of cases where it occurs it is the result of errors in management, and so am I. Cucumber growing, Peach growing, and various other items must be passed, but as showing that the climate is good as well as the soil a plant of *Coronilla glauca*, growing up the wall of the Court, easterly aspect, must be mentioned. It is 8 or 9 feet high, covering a space 4 or 5 feet wide with a sheet of glistening yellow flowers such as are not seen on plants in pots. The protection of a blind is afforded during severe or inclement weather. On the same wall *Eucalyptus globulus* is in the best of health, and has a good and distinct appearance.

Glewston is pleasantly situated, and notable for high culture on the farm and in the garden; for a splendid flock of Shropshire sheep; for its great collection of fruit; unfortunate for the hordes of caterpillars, and fortunate that it is the hands of a gentleman who appears to take delight in doing all things well. His gardener, Mr. S. T. Wright, is such a good man that I can scarcely suppress a feeling of regret in not being able to claim relationship with him. I intended in these notes saying something about Toddington, Lord Sudeley's great and splendidly conducted enterprise in fruit culture. From the trees and bushes it is hoped 500 tons of fruit will be gathered this year for making into jam on the spot by Mr. Beach. Something must be said on the remarkable undertaking, so well managed by Captain Corbett and Mr. C. D. Wise, on another occasion, and more must follow about caterpillars.—J. WRIGHT.

P.S.—Since writing the foregoing I have received the following note from Mr. Campbell, written on the 12th inst:—"Caterpillars are still hatching out, and yet it is nearly seven weeks since they commenced. Where no preventive measures have been taken it is safe to calculate on partial or total loss of fruit crops. It is too early yet to make any estimate, as the mischief is going on in the blooms to an extent of which very few people can have any idea. In spite of the good result from the repeated sprayings with Paris green, I can only speak with any degree of confidence as to the foliage, which I have great hopes of saving. I find that growers, who have taken no preventive measures, are now recognising that

the crop is a failure, and deciding that nothing can be done this season. On the contrary, I urge them to put forth all their energies to combat our foe. The caterpillar is beginning to let himself down to the ground. My emphatic advice is, Spray at once, and keep on as long as you can see a caterpillar, and then you may avert, or at least mitigate, an attack next year. Use, however, only 1 oz. of Paris green to 20 gallons of water, and be especially careful to keep the mixture thoroughly stirred."

PREVENTIVES.

"PREVENTION is better than cure" is an adage familiar to all from the days when it figured as the headline on our copybooks at school, and the forcible illustration of the pedagogue is still fresh in the memory of many an erewhile schoolboy. The successful man in any calling owes most of his success to forethought in preventing occurrences which would have entailed loss of time and much additional anxiety before the enfeebled result of a cure was obtained. Certainly there are events which no amount of ingenuity can prevent, and perhaps it is well that this should be so, although it forms no genuine excuse for the neglect of proper precaution in matters over which we have control. It is only the thoughtful man who finds real enjoyment in his work as he sees his carefully laid plans succeed each other with the same certainty that spoke follows spoke in a revolving wheel. In all matters contingencies have to be provided against, and the stronger the reinforcements in that direction the better.

Each individual seems to think that his own special pursuit calls forth the greatest mental exertion, this doubtless arising from intimacy with its intricacies; and, while not ignoring the work of others, it must be allowed that to be a successful gardener much forethought is necessary. There is the variability of climate which is beyond our control, and frequently makes the system that proved right one year to be quite the reverse the next. This is strikingly illustrated in that very important spring vegetable the Cabbage. Last year early plants were most useful to their possessors, turning in with only a very small per-centage "bolting," and owing to this favourable occurrence many were induced to plant largely at an early date during the past autumn, hoping to gain like results. But the different weather of the past winter has acted on many forms of vegetation in a different manner from its predecessor, so that this spring it is no unusual sight to see whole plantings of early Cabbages with scarcely an exception running to seed. It is at such times as these that the thoughtful man reaps the fruit of his forethought, for instead of trusting too fully to one planting he has reinforcements in succession.

Fruit culture has been receiving much attention lately, and great interest has been centred in its various details, and here again we see that forethought precedes success. Some time ago an account of the Castle Gardens, Cardiff, appeared in the *Journal*, and in the notice of the fruit trees I was especially struck with the winter dressing they receive. How many of the insect pests were destroyed through this agency it is impossible to imagine, and doubtless the annual application prevented some from ever gaining foothold. Many of the failures in fruit growing are rightly attributed to insect agency, and when our knowledge of their habits is more complete—and praiseworthy endeavours in that direction are going on—so that we may be able to catch them napping, we will soon get rid of their contumacy when awake. A thoroughly effective system of winter cleaning the fruit trees would undoubtedly be a good step forward in fruit growing.

A fondness for Roses is one of my failings, and from my intimacy with them I have found that many of the ills which they are heir to can be stopped by the timely application of preventives. Take the grub as an instance; the worm in the bud which blights the hopes and tries the patience of many a grower. It is the sad experience of many to find this enemy eating the bud of the most promising shoot, and the process of searching for them daily at a critical time is the most unpleasant occupation of a rosarian. Many an hour that could ill be spared have I spent in the vain endeavour to annihilate them until, a few years ago, I adopted a course similar to Mr. Pettigrew's with his fruit trees. About the beginning or middle of April, according to the season, just as the buds are bursting, before they show leaf, the plants get a good syringing with a mixture of petroleum, softsoap, and water rather stronger than is generally used for plants in leaf—i.e., two wine-glasses full of petroleum and a small handful of softsoap dissolved in three gallons of water. I cannot account for it being more efficacious at that time than when the buds are quite dormant, but it is so, and it may be that instinct causes the embryo grubs to leave their resting place then to search for prey. This is now a question.

for entomologists, but since using the insecticide grubs have rarely been found in the Rose garden.

Most plants which are subject to the attack of insects at an early period of their growth enjoy greater immunity after the application of this or some other insecticide at a similar stage. The Peach may be taken as a familiar example. Almost before the leaves can be noticed the aphids sometimes begins its destructive work, and if once it gets a footing while the trees are in bloom the crop for both that year, and to some extent the succeeding one also, is inferior. Even after a good winter dressing trees are occasionally infested at this critical time, and the remembrance of one house which I once saw so attacked has made me dread its appearance. It was not in the garden of a slothful man where this occurred, and the efforts to save the crop were tedious in the extreme. As far as my experience goes a dressing such as I have described has been effectual in keeping them in check until fumigation and the syringe can be safely used.

Again, how much of the general neatness of well managed gardens is the result of forethought exercised in that direction? Weeds are prevented robbing the legitimate occupants of the soil through being uprooted by the hoe in their infancy, and confusion is unknown by having a place for everything and everything in its place. Remedies to effect a cure are quite common for all diseases, but preventives are not so largely advertised.—M. D.

NOTES ON FRUIT TREES—APPLES.

(Continued from page 355).

FRUIT trees shelter each other when established, and as they differ in growth and in hardiness it will suffice in most localities to employ the stronger growing and hardiest as screens to the others. Northern Greening will stand quite as much wind as an Oak, and prove far more satisfactory pecuniarily than Lime, Sycamore, or other forest trees. Poplars and Willows are quick in growth and liable to the attacks of grubs and fungi.

In many localities where suitable sites exist for fruit plantations, hedgerows have been allowed to attain proportions little inferior to trees. Such ready-made shelters should be scrupulously preserved entire on the north, north-east, and north-west sides, opening out somewhat on the east and west, but leaving enough, however, to break the violence of winds from those points. From south-east to south-west the hedge may be cut as judgment determines, so as to afford in due course the requisite protection against intruders. No more trimming should be attempted on the other parts than will contribute to the formation of a good fence ultimately, but keeping in view that shelter for a few years is of primary importance.

Where such ready-made shelters do not exist and the location is not very bleak, it will not be necessary to incur any expense in providing shelter by planting, for whatever is planted will take time to become established so as to afford protection in any way beneficial to the fruit plantation, and by that time similar results may be attained by a judicious employment of the hardier and stronger growing fruit trees on the most exposed sides. On the north, north-east, and north-west sides Northern Greening alternating with Minchull Crab may be planted; inside those a line of Alfriston and Bramley's Seedling; and a third row of Baxter's Pearmain and Galloway Pippin. Those planted alternately 30 feet apart will ultimately afford all the shelter required from those points, but as immediate shelter is required the trees should have a temporary one planted between them in the lines, than which none stand wind better than Manx Codlin, Carlisle Codlin, Devonshire Quarrenden, Worcester Pearmain, and Dumelow's Seedling. Between the rows a line may be planted of Dutch Mignonne, King of the Pippins, Fearn's Pippin, and Greenup's Pippin (Yorkshire Beauty), so very efficient shelter would be provided by five rows of trees 15 feet apart, which would be profitable from the third year of planting, and in a dozen or more years will have amply repaid the first cost, independently of their value as shelter up to that time, when the other or permanent trees will have grown so as to necessitate their removal.

On the east and west Dutch Mignonne, King of the Pippins, Fearn's Pippin, and Lemon Pippin may be efficiently employed, the two first alternately in the second line, and the two former in the third, for as an outside line on those points Blenheim Pippin and Bess Pool are to have place alternately. Both are strong growers, stand almost any wind (I have seen Blenheim Pippin quite luxuriant over 500 feet above sea level in the Principality), and they help sometimes after fifteen to twenty years' uselessness in filling the fruit basket. The alternating distance can be filled both in the lines and between them with the hardier free early fruiting sorts, so as to have the trees 15 feet apart every way. This will give an enclosed space, in which can be grown the

kinds requiring shelter and warmth, and instead of the "twopenny-halfpenny" system of planting, let the whole of the space be covered with trees half the distance apart they are ultimately, both as to the rows and the trees in the rows to remain, and they will give in seven years a better account of themselves than under the usual plan of sticking in trees 24 to 30 feet apart, and getting only profit of a quarter the ground in seven years, and not half in fourteen to twenty-one years.

To plant an acre at 30 feet apart only requires forty-eight trees. Seventy-five trees at 24 feet, and at 12 feet 302, or 15 feet 193, which is not overwhelming as regards first cost, and the trees do not have to struggle against wind for two or three years ere they become acclimatised (for we must bear in mind there is a great difference between trees grown in nursery lines not as many feet apart as we propose to put them in yards under the quarter distance system recommended). Whatever may be thought of the distance, it is only what the nurseryman practises with trees under the dwarfing system, by which means they are much healthier, and though bearing may be somewhat delayed, it is marked by a decided increase and enhancement of product. Anyone planting a mixed hardwood plantation—Oak, Ash, Elm, Sycamore, &c., 20 feet apart without putting in the nursing Larch, Scotch Fir, Spruce, Austrian and Corsican Pine—the 2614 in order to shelter and bring on the 108 hardwood trees of the permanent plantation would be thought extremely careful of killing the goose that lays the golden eggs, and it tells far more against the planting of fruit trees. They require shelter to rear to planting size, at least it is most profitable to do so, and as it is effected by having them at such distances as to shelter each other, it is strongly advised as the only means by which fruit can (recourse not being had to intermediate cropping) be grown to command the market and return a good per-centage on the outlay. This, of course, would necessitate trenching the ground, thereby adding to the first expense a sum equal to the cost of the trees. What of that? It is the haphazard system of planting fruit trees anywhere and anyhow that has thrown the "plums" into the hands of the importers. If land will not pay to cultivate it is much better left alone, and instead of grumbling at those supplying our markets with wholesome cheap food, accord them the credit due to their superior knowledge, enterprise, and industry. By digging a pit in grass and sticking in trees 24 to 30 feet apart, we are as likely to supply the markets with British grown Apples as ever; besides, it is a sheer waste of energy.

Whether we have a fruit garden—i.e., dwarf trees or an orchard, shelter is a foregone conclusion. It can be either of the trees themselves as before stated, or special sheltering subjects employed. In dealing with a fruit garden it may not be necessary to employ large or standard trees, but have dwarf standards, or such as have stems of about 18 inches. These may be on the Crab stock, and planted 15 feet apart every way. The kinds and order of planting may be the same as detailed for orchards. Three lines will give all the shelter required, the trees being trained as hushes. The interior could be divided into quarters by lines of espaliers 6 feet high running east and west and north and south, the quarters being about 25 yards square, which distance I find quite sufficient to break the curling or eddying force of wind after its force is broken by the sheltering trees, and the less the wind acts on the fruit quarters the less warm air is blown out of them, to be replaced by cold. The same thing in a different manner can be effected by planting lines the reverse way; the others being north and south may have a cross row, or east and west, at every 25 yards instead of the espaliers. This does not materially interfere with the cultural operations, and it exerts considerable influence on the currents of air, which control the absorbing, retaining, and radiating power more than is generally supposed. What we want is warmth in the enclosure and to retain it without liability to sudden transitions, which are more liable to occur on slopes than on level ground. With suitable soil and location sheltered from north, north-east, and north-west winds, with the easterly and westerly gales tempered by broken or open shelter, and a free clear embrasure between east and west to let in the sunbeams, fruit culture may be entered upon with every reasonable prospect of success.

FENCES.

Whether a fruit garden or an orchard be made, a fence of some kind will be necessary. For a fruit garden oak palings (rended) are certainly durable, and being 6 feet high with a line of thick-set four-barbed fencing wire along the top a fence practically unassailable is formed, and it has the advantage of being available on the interior for trained trees of the choicer kinds, the north aspect being equally eligible for larger fruited hardier sorts. As a hedge nothing surpasses a quickset or Thorn, with enough Holly to impart a cheerful appearance in winter. Seven Quicks and one Holly per yard, planted in ground properly trenched and manured

and duly attended to in cleaning and trimming, will make a good hedge in four to six years. It will form a barrier in due course that will effectually stop intruders.

In locations near the sea winds are sweeping through, there being little wood, copse or hedgerow trees to soften their effects or break their force. Of all subjects that I have seen used for the purpose of shelter on the sea coast none had the vigour and sturdiness of the common Elder (*Samhucus niger*). A double row of plants, a foot apart, form in a short time a capital screen for fruit trees on the dwarfing system, which appears best suited to these locations, as it is difficult to get anything upon a plane surface sufficiently tall to protect standard trees. In some "burns," however, this is readily effected by Willows and Poplars, planting them about a yard apart so as to get up quickly. In these miniature valleys the ground slopes sharply, and has a sort of plateau here and there in the descent, which are taken advantage of by fishermen and others for gardening purposes, on some of the southern slopes of which I have seen as fine Apples and Pears grown as any reaching our markets from Canada or the Channel Islands, and at the base of these slopes there may often be seen a good sized orchard, which from the deposit of matter washed down from the higher ground, and the stream running higher than it does now, had a good depth of soil, in which the Apple luxuriates. These locations have the disadvantage of liability to suffer from spring frosts; indeed the trees there may often be seen fruitless when the bushes at an elevation of 100 feet or more on the slope are carrying heavy crops of full sized highly coloured fruit. In other respects they are admirably suited to the growth of Apples, being sheltered to the north by the acclivity, and it is not difficult to afford shelter from the west and east by planting Willows, Poplars and Sycamores, with Mountain Ash, wild Pear and Elder for undergrowth. As a hedge plant the wild Pear (*Pyrus communis*) is unequalled on the sea coast. It should be planted 6 inches apart, the ground being well trenched and manured so as to encourage free growth. It will make a hedge effectual in every way for a fruit garden.

PLANTING HEDGEROWS.

Planting fruit trees in the hedgerows of fruit gardens and orchards may be desirable, or rather feasible, if the proprietor or tenant own or rent the adjoining land. Land that grows good timber will grow Apples, but the farmer looks upon the removal of hedgerow timber as a great aid to successful cultivation, and it must be admitted trees in hedgerows prejudice the ground as far as their heads overhang and the roots extend. There is no certainty of a fence or crop whilst the trees remain. Fruit trees in the hedge of a fruit garden or orchard may be regarded in the same light. They may be used to the prejudice of another, and interfere with the keeping of an unbroken fence. It is only when the trees become aged and close headed that they are injurious to the fence, as up to a certain stage (which extends to the better part of their days) they are beneficiary as shelter and in fruit production. Up to a certain size and age Apple trees grow quite as freely and as abundantly fine, or finer, fruit trees in an orchard in grass from the circumstance that the ground has been thrown up and deeply stirred for the quicks—an advantage of amelioration and condition of soil of which the trees are not slow to avail themselves. It follows, however, that soil permeated by the roots of the hedge plants and trees will become sooner exhausted, the trees will overpower the fence, when it is of course a question as to which shall go to the wall. That is so remote a contingency that it may be excluded from present consideration, besides it is easily remedied when the time arrives by a retention of the "fittest."

In planting the hedge with trees we must bear in mind that we lose half a row internally, as by planting trees in the hedge we must put the first line of trees half as far away from the fence as where there no trees in the fence, unless no account is taken of the trees in the fence, only relying on them for shelter and fruit in the early stages of the fruit plantation. This would, perhaps, be the best lines on which to set out, planting in the first instance with a view to shelter and early profits, and as experience is gained thinning can be effected in accordance with exigencies as they arise, which can only obtain where judicious planting has been made—namely, thick as compared with current method, in order to get shelter, a reasonable, early and increasing return on the outlay.—G. ABBEY.

(To be continued.)

INSECTS OF THE FLOWER GARDEN.

(Continued from page 253.)

A very beautiful beetle, almost an inch long, which sometimes disports itself upon our flowers during May is called the "Cardinal," from its colour, or in Latin *Pyrochrea coccinea*. The thorax and

body are scarlet, also downy; the head black, having a curved mark of dull red between the eyes, and the antennæ are elegantly toothed. It nibbles slightly the petals of flowers, but is not guilty of doing much damage. As larva its life is very different, for then it inhabits the wood of decaying Poplars or Willows. Nearly related to the Cardinal beetle is a species generally visible about the same time, for which we have no English name, so must call it *Rhipophorus paradoxus*, but it is less than half the size. This insect is partial to the flowers of Umbelliferous plants, and to the cymes of such species as the Guelder Rose. On the slightest alarm, however, it bends down the head under the thorax, hides its longish antennæ, and raises the wing cases, which are orange and black. Possibly this odd movement is a precaution against an attack from a hostile wasp, for it is now a well-ascertained fact in the history of the species that the larva or grub preys upon the grub of the common wasp, and therefore it must be accounted a somewhat useful insect. How the beetle manages to travel about amongst the cells to deposit eggs, and also when reared how its offspring escapes unobserved, is rather mysterious. It is noticed that extra large beetles emerge from the grubs that have been so fortunate as to feed up in the cells of queen wasps. If this species subsists, as beetle, upon flowers it is not capable of damaging them materially. That pretty but rare beetle, the Spanish fly, Blister beetle, or *Cantharis*, has occurred in gardens upon the flowers of Privet and Syringa, and its tints of green and gold might attract persons to it, so that we need not regret its scarcity with us, for, both living and dead, it is a dangerous species to approach near.

I have now reached the group of beetles which contains the bulk of those that are specially injurious to vegetables, fruit, and flowers, but which do not cause so much loss in the flower garden as in other departments; still many species appear there in large or small numbers, and they bear the familiar name of weevils, a word apparently derived from the old German *wifel*, curious because it is said to mean something woven, and is probably an allusion to the closely spun cocoons of some species. They are also called "long-nosed" beetles, the head being lengthened so that it forms a kind of snout, upon which are the antennæ. In front are mandibles or jaws furnished with muscles of surprising strength considering the size of the beetles. A few of them can produce a slight sound by vibration of the wing cases, and a few others that frequent woods have the power of leaping. The grubs of all the weevils are short and stout, usually whitish, and they are, as in the Pea, Bean, and Nut species, exceedingly mischievous.

The Pea weevil, so familiar to all who shell Peas, is an insect we may at some time or other notice upon the flowers of our beds, but so far as I have observed it limits its attacks to the edible Pea, the ornamental species escaping. Much more frequent in gardens is the Bean weevil, a tiny creature which looks grey, though its colours are really black and white. It haunts the early flowers of spring, presumably for their honey, and then betakes itself to the rows of Beans as soon as the pods are beginning to form. Less even than the weevil of the Bean is the host of minute beetles belonging to the genus *Apion*, which have received the English name of Pear weevils, because their bodies, if magnified, resemble Pears in shape, the head of the insect representing the stalk. We may see them upon flowers by hundreds and thousands. In their larval life they dwell within the roots or stems of plants, occasionally we discover that they are tenants of some gall-like swelling upon leaves. Under the microscope they are most interesting objects, both from their varied colours and curious tracery on the thorax and wing cases, and the majority do no serious damage to our flowers, though they may disfigure a few plants. The one which has been most frequently complained of is *A. radiolum*; it deposits eggs in spring upon the stems of several herbaceous plants, being partial to the Hollyhock. The grubs feed within the stem on its pith, become pupæ there, and appear as beetles in October, hiding somewhere during the winter months. Some people introduce into their gardens specimens of the Mullein, or a variety, it being somewhat showy, if not a choice species, and this plant is the favourite resort of weevils, their larvæ nestling in the woolly leaves, upon which when full fed they spin netted cocoons of silk.

The larva or grub of the grooved or black weevil (*Otiorhynchus sulcatus*), a well-known pest of fruit, occasionally turns up in the soil of beds and borders, but it is chiefly troublesome from its habit of infesting plants in pots both in and out of houses. Its favourite position is just beneath the earth, where the roots radiate from the stem; one even has been known to kill a good sized plant, but they generally occur in small parties. These grubs are legless and hairy, white or dull yellow, and live from August to April, when they cease to eat. The beetles are about in May and June, and they creep upon the soil in an insidious manner, getting partially under the earth, so are seldom noticed while depositing their eggs. I may note that clear lime water has been recom-

mended for the destruction of this grub in pots or borders, a decoction of quassia with softsoap is fatal to it, and a solution of hellebore kills it; but this cannot always be conveniently applied to infested plants. An application of petroleum diluted, strength 1 oz. to 2 gallons of water, has been recommended. Happily, there are two or three species of weevil that are quite different in habit from the rest of the group. These belong to the genus *Anthribus*, and in their larval state prey upon the scale insect or coccus of various kinds. Hence, so far as they can be recognised by the gardener, they should be left alone both in and out of doors, for Nature's parasites do a great work in preventing the rapid increase of species. The *Anthrabi* are distinguished from their relatives by their clubbed antennæ. The grubs are hairy, and appear to attack principally the female coccus, preventing the development of her eggs.

A not uncommon garden beetle of the long-horned family is that called the wasp beetle (*Clytus arietis*). When it is seen upon flowers most persons feel inclined to avoid it, for its aspect and movements suggest that it must belong to the wasp family. The head and thorax are black, the latter globular, and the body is yellow, ringed with brown. This insect can fly and also run rapidly, owing to its long legs. It is, in fact, a mischievous species, and we find out the harm it can do not unfrequently when we examine into the state of garden palings. These may be found reduced to a condition like tinder by the operations of the larvæ of this species, sometimes living in parties of twenty or more, small, but with broad muscular bodies and horny heads. Another beetle that, like the preceding, is abroad in June is conspicuous, but in a different way, and more directly troublesome to the horticulturist; but of late years it has been scarce fortunately. It is akin to the too plentiful *Asparagus* beetle (*Crioceris asparagi*), and has been called the Lily beetle. In length it is about a third of an inch, and in colour bright scarlet. The squat grub feeds upon the leaves of Lilies, Daffodils, Gladioluses, and allied species. It received the name of *C. merdiger* from its peculiar habit of forming a protective cover of the excretions, beneath which it feeds securely, and is also sheltered from the sun.

In leaving the great order of the beetles it is only needful to mention the abundant insects of the last division—the ladybird tribe. These, in their beetle or larva state, may be seen from March to September upon almost every plant, their object being a good one, the destruction of the aphides or flies, by which so many of our choice plants are infested and greatly weakened if not killed.—ENTOMOLOGIST.

FORCING SWEET PEAS.

IN accordance with your request, it affords me much pleasure in relating the culture of the above practised here. In many places, where large quantities in succession of sweet scented cut flowers are in demand, I can recommend these as a good substitute. When they are gently forced under glass in a temperature ranging from 50° to 60° Fahr., with abundant ventilation in favourable weather, they are among the most delicate and beautiful flowers; especially as they need so little attention, and give a good supply of flowers. They are grown in a compost of turfy loam slightly enriched with decayed hotbed manure. The first sowing is made the first week in June for late autumn supply, in boxes or 10-inch pots, which size is most suitable for conservatory decoration, and grown outdoors in full exposure until the approach of frost, when they are taken inside, and, being full of flower buds, expand freely in the above-named temperature, and give a good supply of flowers onwards to Christmas.

A second sowing of the Sweet Peas is made early in August. When these are taken inside they are wintered in the vinery, Peach, or Fig houses at rest. When forcing commences in these houses early in January, they remain here until the night temperatures are raised to 60° Fahr., whence it becomes necessary to remove them to other succession houses at from 50° to 55° at night. If warmer than this I find the growth becomes elongated, they refuse to flower freely, and consequently they fall a prey to green fly. A moderately warm dry atmosphere, with abundant ventilation, suits them admirably. Plants from another sowing late in December in 5-inch pots are grown in cold frames until 5 or 6 inches high, when they are planted out on a warm border, and ultimately form a good succession by the time the August sowing is exhausted. Then with still further additional sowings outdoors, there are few months when we are without them. There are times during hot dry weather, when they refuse to flower freely outdoors, owing to seed podding, but if denuded of these with the shears, accompanied with a good watering, they break freely into growth, and will well repay the trouble bestowed upon them.—J. T. EBBUTT.

MARIANTHUS DRUMMONDIANUS.

THIS charming little blue-flowered twining plant is but seldom seen, and is known by few cultivators, though it was introduced to

public notice some twenty or thirty years ago. Early in the present season a specimen flowered extremely well in one of the houses at the Crystal Palace under the management of Mr. W. G. Head, and the freedom with which it produced its flowers, and the long period during which they lasted, amply proved the value of the plant. It succeeds in a compost of light loam, peat, and sand, in a greenhouse or any other cool structure.

The plant has been thus described by Sir Joseph Hooker:—*"Marianthus* of Huegel is a genus now, according to Mr. Bentham, including fourteen species, of which all, except two (*M. procumbens* of New South Wales and *M. bignoniaceus* from Victoria and South Australia), are natives of Western Australia, and chiefly from the Swan River settlement. The blue-flowered species are extremely

FIG. 59.—MARIANTHUS DRUMMONDIANUS.

pretty, as may be seen by the present figure, and by that of a nearly allied species given at t. 3893, *Marianthus coerulescens*. The *M. Drummondianus* is a more slender and graceful twiner than that, while the flowers are of a paler blue. Whole plant, except the petals, more or less villous or ciliated (in the leaves) with soft patent hairs. Stem filiform, long twining, branched with short patent branches, the upper ones especially flowering copiously. Leaves 1 to 2 inches long, oblong or lanceolate, scarcely petiolate, rather acute, lower ones toothed or subpinnatifid, the rest entire at the margins, smaller upwards. Peduncles very slender, terminal and lateral subcorymbose; pedicels elongated, filiform, with a small bract at the base. Calyx of five linear, subulate, erect, distantly placed sepals. Petals spatulate, very acute, bright but pale blue, the claws erect, the lamina spreading. Stamens five, much shorter than the petals. Ovary cylindrical, stipitate,

gradually tapering upwards into a short style. Stigma small, capitate two-lobed."

PRESENTATION TO MR. W. BARDNEY.

A MOST enjoyable gathering of gardeners and the horticultural trade took place on Saturday evening, the 10th inst., at the Falcon Restaurant, Lord Street, Liverpool. The occasion was a farewell dinner and the presentation of an illuminated address to Mr. W. Bardney, who is leaving Norris Green, West Derby, to take charge of the beautiful gardens of Osmaston Manor, near Derby, the seat of Sir A. B. Walker, Bart. Mr. Thomas White occupied the chair, in the absence of Mr. W. Tunnington through indisposition. Mr. J. Glover was in the vice chair. About seventy gentlemen partook of an excellent repast. After the loyal toasts were given and duly honoured, the Chairman, in submitting the toast of the evening, "Our Guest," referred to Mr. Bardney as our representative and friend, who was well known and highly respected in the surrounding district, and his common-sense articles that had appeared in the *Journal of Horticulture* during past years were highly appreciated and a gain to horticulture by the valuable information they afforded. On behalf of those interested in horticulture in Liverpool, he had great pleasure in presenting Mr. Bardney with an illuminated address as a proof of their esteem, wishing him health, happiness, and prosperity in his new position. (Sustained applause). Messrs. J. Glover, T. Davies, H. Middlehurst, A. R. Cox, and others supported the Chairman's remarks as to the abilities and unvaried courtesy of Mr. Bardney, and of his integrity and uniform honesty in his writings, and his practical worth as a gardener.

The illuminated address was well designed, and enclosed in a neat oak frame. The inscription was as follows:—"William Bardney.—We, representatives of the horticultural trade and gardeners in the neighbourhood of Liverpool, take the opportunity on your leaving Norris Green, where you have been for a period of 12½ years as head gardener, to present you this address as a token of our great esteem, and whilst regretting the loss of one who has done so much in the interests of gardening in this neighbourhood, we congratulate you and wish you every success in your new undertaking at Osmaston Manor. We trust that in the future we may be benefited with your contributions to the horticultural press as heretofore." The address was signed—R. P. Ker and Sons, Thomas Davies & Co., Henry Middlehurst, R. Rowlands, C. Young, J. Williams & Co., Thomas White, John Glover, R. G. Waterman, Edward Bridge, J. Massey, S. Whitfield.

Mr. Bardney, in rising to respond, was received with much enthusiasm. He thanked the company for the kindly words that had been spoken, and for their cordial reception and splendid address. The kindly gathering of so many friends on this occasion would never be forgotten, and the address would continually remind him of their friendship and esteem. In reference to his writings in the horticultural press, he had always endeavoured to write for those requiring information. Those who have advantages and opportunities should at all times be willing to give of their knowledge in the cause of their pursuits. He was leaving Liverpool with deep regret, as it was leaving a district of unusual merit in horticulture, and where he had enjoyed the friendship of a large number of those engaged therein. In his new position he hoped to merit the approval of his employer and the continued esteem of all those engaged in horticulture.

Mr. R. W. Ker, in responding to the toast "Horticulture," spoke of the genial brotherly friendship existing amongst all connected with horticulture. Other toasts included the Chairman, Mr. C. Young, organiser of dinner, Mr. H. Middlehurst, and the thanks of the company were tendered to Messrs. P. Jackson, G. Hulatt, W. H. Read, W. Bramham, and R. G. Waterman for their excellent services in the musical portion of the evening.

[We join in congratulating Mr. Bardney on his appointment to his new charge, and are well assured that he possesses the necessary qualifications for managing successfully the large and well equipped gardens at Osmaston.]

THE CARNATION.

(Continued from page 385.)

[PRIZES for essays on the Carnation having been offered through the Ealing Gardeners' Improvement Society, Mr. Charles Turner, the adjudicator, awarded the first prize to the following useful contribution of Mr. David Cooper, foreman, Gunnersbury House, Acton.]

SEED SAVING.

AS I have already remarked raising seedlings is a very interesting way of increasing the stock, especially when we fertilise and save seed from our own plants. The Carnation, as a rule, is not a prolific plant, and the more double the flowers are the less likely are they to seed. Therefore semi-double blooms are the best for that purpose. But very much depends on the season, for as it is a rather late flowering plant the seed has not much time to ripen. When the seed-pod begins to swell, showing signs of containing seed, which will be when the flower is fading, the withered petals should be pulled out from the corolla to prevent any damp collecting upon it, as that would retard the ripening of the seed. Great care should be taken in removing the petals not to

injure the styles, or all chances of success would be destroyed. The seed should not be gathered until fully ripe, which will be about the middle of September, and it will then be almost black in colour. The pods should be cut, put on a sheet of paper, and placed on a shelf in a dry airy situation near the glass to finish it off, as it were, for about a fortnight. Afterwards carefully rub it out, and if not intended to be sown until the spring it should be stored away in a cool dry place. It would be almost two years from saving the seed before the worth of the flowers is ascertained. And since the Carnation is such a variable flower it is almost certain to produce many worthless kinds; but if one good new variety be secured in a season an enthusiastic cultivator would be amply repaid for all the labour.

INSECTS.

The wireworm is one of the most destructive insects to Carnations, and is generally brought into contact with it in the loam and leaf mould, especially if it has been allowed to lie outside in the rain. It is easier to detect in the latter on account of its colour, which is of a yellowish cast, and it is nearly an inch in length. It attacks the plants at the roots, and will soon make sad havoc among them if not quickly disposed of when detected. This is not an easy matter, as it works below the surface of the soil. If the plants show any signs of being attacked by it a trap may be set by inserting a piece of Carrot in the soil near the stem, which would be almost sure to attract them, examining it from time to time, and destroying any found. Soot water is an excellent remedy to drive them away, but the destruction of them is doubtful. In preparing and turning the soil a sharp look out should be kept, which would be the most effectual remedy as regards pot plants.

Earwigs.—These, I believe, form the most troublesome pest to deal with on account of their travelling propensities, eating and disfiguring so many flowers in such a short time. They attack the blooms from the time they are in bud until they are over, eating the petals through at the base, going through the calyx if the corolla is not expanded enough. I do not know any means to prevent their attacking the blooms except that they should be well sought after during the night, which is generally their feeding time, with a lamp, showing the light on them suddenly, as they drop on the ground as soon as they are disturbed. Bean stalks make good traps. Cut them in lengths about 6 inches long, putting them near the stem of the flowers. They will conceal themselves in the bean stock when it begins to get light; they should be looked for every morning and blown out into a can of water.

Greenfly.—This is another pest the Carnation is subject to, and if remedial steps are not taken to dislodge them as soon as they appear they will increase with alarming rapidity, and will seriously affect the health of the plants. The insecticides used for their destruction are numerous, but when injudiciously applied often cause more injury to the plants than the aphides do. If the plants are infested with them before the blooms begin to expand steep some quassia chips at the rate of 2 ozs. to 1 gallon of water, applying it with the syringe, which is not only a good remedy for destroying the insect, but an excellent preventive. The same might be applied when in bloom with a little tobacco juice added, using a soft brush, taking care it does not touch the bloom; or if convenient, and the buds are not too far opened, fumigating with tobacco would bring about the desired effects.

Grubs.—These, like the earwig, attack the flowers in the night-time. They are from 1 to 2 inches long, of a greenish colour. They feed on petals, eating holes through the calyx, and will also devour the young growth. In the daytime they might be found buried in the soil near the stem. The best remedy is hand-picking at night with a light.

I will now make a few remarks with reference to another enemy, which is sometimes called a disease. Anyone conversant with Carnations would have noticed the top of the foliage will occasionally become crimp and hard, stunted in growth, and with the least touch will fall off. This is caused by a very small insect (which cannot be discerned by the naked eye) of the spider tribe. They affect many other plants in the same way. They are more noticeable in Carnations when in a young state, especially during the winter and early spring months. The safest and most effectual remedy is by dusting the parts affected with tobacco powder, slightly damping the foliage so that the powder will stick on, repeating the operation when necessary.

DISEASES.

Spot is a disease unhappily known among Carnations, taking its name from the manner in which it affects the foliage of the plant. This occurs more in the winter during damp and close weather. It is

caused by water coming in contact with the leaves, which is sometimes done by careless watering in the case of plants under cover. Outside it totally rests with the weather and the class of protection afforded. For this quicklime might be used with good effect, dusting the plants all over, and a little soot mixed with it would do no harm.

Mildew.—This is a very troublesome disease to be guarded against, and is almost sure to attack plants if they be kept close and warm, which should at all times be strictly avoided. Should it make its appearance, flower of sulphur may be shaken over them through a piece of muslin or a sulphur distributor. There are many preparations used for this malady, but I believe the old-fashioned one recommended above to be the most effective.

There is another disease I might mention, but I must frankly confess that my knowledge of it is very slight. It comes in the shape of an insect mite that attacks the roots, working its way through the centre or pith and ascending into the stem. Plants when attacked soon begin to turn yellow and assume a sickly appearance. If allowed to go unchecked it will often affect the whole stock of plants, which will soon become an eyesore and a source of annoyance to the grower. In this case I should advise soot to be used, shaking a little over any plants that show signs of becoming a prey to this insidious disease, and watering with soot water. But the better plan, when the foliage is showing any suspicion of the disease, is to take the plants and burn them; thus sacrificing a few might be the means of avoiding all further trouble and anxiety.

WINTER TREATMENT.

Presuming the layers and cuttings have been rooted and potted, I might be allowed to give a few hints respecting their winter situation and treatment. Cold frames or shallow brick pits would be the best place to keep Carnations during the above season, having several inches in depth of coal ashes at the bottom to stand them on and to keep out the worms, having the plants near the glass, and giving abundance of air, removing the lights altogether in the daytime, and leaving them tilted at night in mild dry weather, and in wet weather they should be tilted in opposite directions to the wind, either sideways, top, or bottom. A little air might be afforded them for an hour or so in the middle of the day in frosty weather if the frost is not too severe. They are less likely to be injured by two or three degrees of frost than by keeping them close and covered for any length of time. Of course this is unavoidable sometimes when there is a long spell of sharp weather, but a chance of giving air should never be missed. For covering the frames straw mats are the best, as they can be rolled on and off with ease, besides keeping out more frost than many other materials used.

Watering.—This should be done very sparingly during December and January, and should be done with a small-spouted can, never using a rose on account of wetting the foliage, choosing bright days and early in the morning. They should never be allowed to get too dry for any length of time, as the stem will lose its pith and thus be seriously injured. Steer between the two extremes as near as possible. They should be gone over at intervals, picking off any decayed leaves, and keeping a sharp look out for any disease or vermin, and as soon as observed take measures against it at once. If the soil gets green and crusted on the top, it might be stirred occasionally with a pointed stick. Towards the end of February, if the weather be mild and genial, the plants would be greatly refreshed if allowed to receive the benefit of a gentle shower, coming from the south or south-west, for a half hour or so, taking care to get the foliage dry again as soon as possible. Any plants that have been left in the open ground should be protected in the manner advised for seedlings.

TREE OR PERPETUAL CARNATIONS.

Anyone acquainted with the London or other flower market of consequence, will know to some extent how highly this Carnation is esteemed by the quantities that are disposed of there. Unlike many other flowers they never appear to be out of season, and as I remarked before, they are decidedly the best for pot culture. There are numbers of sorts grown both for private and market purposes. For the latter the delicate flesh colour variety of *Souvenir de la Malmaison* and *Miss Jolliffe* seem to hold the sway, and are estimated at no mean value by almost all cultivators.

Propagation.—This can be done in July and August, or in the following January, either by layering or cuttings. It would be advisable to propagate at both seasons, as by so doing there will be two sets of plants in different stages of growth; by this means, and growing early and late sorts, and regulating them by stopping, you prolong the

flowering period a considerable time. All plants that are rooted the two former months can be done on the same principles laid down for summer flowering varieties, and potted in small pots according to their size and habit of growth, and wintered near the glass in a greenhouse or some cool structure, giving plenty of air during the day whenever possible; and if the ventilators are so constructed that they can be used without fear of the rain beating in, a little air should be left on at night in favourable weather. The temperature should not go below 45° at night, or above 50° with fire heat, but sufficient warmth should be afforded to keep them gently moving, using judgment in regard to watering, and taking the same precaution as to vermin and diseases. If green fly be troublesome fumigate with tobacco. About the beginning of February shift the plants into size larger pots, and so follow on as they need it, until they are in the sizes required to flower in; 32's to 16's would be convenient for that purpose. The compost for potting should be about the same as is used for the summer flowering kinds except a little more loam in proportion, with a little broken charcoal, should be added. During the summer they should be placed outside, where they would be sheltered from high winds. The most tender sorts should have cold frames for their summer quarters, or skeleton frames might be made so that lights could be put over them to protect from heavy rains; and if the whole could be so protected it would be a great advantage, as sometimes during the summer we get heavy thunder storms and occasionally hail, and if not protected the young shoots are damaged, while the roots may be too wet. The plants should be properly staked. When the roots have well filled the pots they should be supported with weak liquid manure, using sheep dung if procurable, if not cowdung, preparing it as before directed. Soot water prepared in the same way may be used (not too strong), giving it about once in ten days, and liquid manure alternately for a week, then resting a week. This will serve as a general guide, but judgment should be used, as some sorts are more gross feeders than others. As soon as they show signs of blooming the tops should be taken out (which in ordinary seasons would be about the middle of June) and at frequent intervals throughout the summer the tops of the side shoots. If early flowers are desired to succeed the late summer varieties a few plants can be selected of the sorts required, and the stopping regulated so as to get them into bloom about the second week in September, taking them under cover a week or so previous. About the above date the whole should be placed inside, and allowed to follow on flowering during the autumn and winter until about the middle of January, when propagation should commence again, and spring-struck plants should be just coming into flower. Either method of propagating could be resorted to at this season.

If layered a good plan is to plunge them in a warm pit, or in a Peach house or vinery, that is started, where there would be a brisk moist heat, spreading the shoots all round the pots, and layering in light prepared soil, where they should quickly take root; or they can be struck from cuttings, selecting the medium size side shoots, as they will be more likely to root than the large gross ones. Soil for this purpose should consist of two-thirds loam to one of leaf mould, sifted and mixed with plenty of sand; over the crocks put a layer of fertilising moss, crumbled to prevent the fine soil from getting among the crocks, also for the small rootlets to strike in, and from which they can be separated without much fear of breaking them, filling up the pots within an inch from the rim, finishing off the remainder with sand mixed with a little powdered charcoal. Dibble in the cuttings firmly, about six to eight in a 4-inch pot; give them a good watering, and plunge in bottom heat of about 75°. The propagating pit would presumably be used at this season, and if the temperature be over 70° the lights should be removed, providing the house temperature is about 65°. When sufficiently rooted they should be potted off (also layers), gradually hardened, and taken into a cool house, where they should remain until safe to go outside, potted, and treated in the same manner as previously stated as regards staking, watering, topping, &c. These plants that were rooted in the above-named season should be topped later, so that some will be coming into bloom about the beginning of the following year, to succeed those that have been flowering during the late autumn and winter, which will then be going off and used for propagating, and may continue until the summer-flowering varieties are in bloom. Thus by having two sets of plants, both early and late sorts in each, by skilful culture and good management starting them into flower when about one year old with a good selection, including the summer flowering varieties, I see no reason why Carnation blooms cannot be obtained all the year round. Old plants

should be grown throughout the summer, or might be planted out to furnish cuttings and layers the ensuing July and August, besides giving a quantity of flowers.

(To be continued.)

EVENTS OF THE WEEK.—As noted in another paragraph, the Covent Garden Fête, on behalf of the Gardeners' Orphan Fund, will be held on Wednesday next, May 21st, from 8 to 12 P.M. The Society of Arts will meet on the same date at 8 P.M., and the usual auction sales will be held in London.

— **THE WEATHER IN THE SOUTH.**—Frequent and heavy rain has distinguished the weather of the past week, and in light soils or high lands this is an advantage that can be duly appreciated in May. In low situations, and where the soil is heavy, it is a doubtful benefit, and in some cases the land is saturated or even overflowed. Generally, however, the rain will help vegetation greatly. The deciduous trees have made rapid progress, all except the latest being now in full leaf. For some days the wind has been easterly, and consequently cold; lately it has changed to a south-westerly direction, with a corresponding rise in temperature.

— **THE WEATHER IN THE NORTH.**—May 5th-12th. The weather has during the week been seasonable, with occasional showers, which did much good. Last night rain fell heavily for hours. Easterly winds have generally prevailed, but growth has been rapid everywhere. The thermometer has never been under 43°.—B. D.

— **GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—In our advertising columns will be found a list of contributions in view of the fifty-first anniversary dinner to be held on June 12th, under the presidency of Mr. H. J. Veitch, the Treasurer. There are, doubtless, a large number of gardeners and others who will be glad to enhance the funds, on the occasion, of this valuable Institution.

— **GARDENERS' ORPHAN FUND.**—The grand Floral Fête and Promenade in aid of the above Fund will be held, by permission of the Duke of Bedford, in the wholesale Flower Market, Covent Garden, on Wednesday next, May 21st, from 8 to 12 P.M. The Lady Mayoress has consented to open the Fête, and the band of the Royal Horse Guards will perform a selection of music from 8 to 11 P.M. The tickets (limited to 2000) are 5s. each, and can be obtained from Mr. J. Assbee, Market Office, Covent Garden, or the Hon. Sec., Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick.

— **NOBLE STRAWBERRY.**—I have had a few pots of this Strawberry, the size and colour of the fruit not to be surpassed by any other variety, but the fruit has no flavour. My employer describes it as dry and not worth eating. Vicomtesse Hericart de Thury, growing on the same shelf, is splendid, and a great favourite here. Will Mr. H. S. Easty, or any other correspondent, tell us about the flavour of Noble, and if it requires any special treatment?—CRAVEN.

— **CALMON'S RED UNIVERSAL HOSE.**—We have received from Messrs. Clarke & Co., 3 and 4, Great Winchester Street, London, a sample of hose under the above name, which possesses several excellent qualities. It is well made, light, yet remarkably strong, very pliable and elastic. One special character claimed for the hose is that it is not liable to harden or crack, and its appearance justifies this assertion. It is admirably adapted for garden purposes.

— **THE DOUBLE FURZE.**—This is a valuable plant for seaside planting. At the present time it is in full bloom, its double golden flowers having a grand effect amongst other shrubs. It makes a fine hedge and bears clipping remarkably well, but it is seen to the best advantage when allowed to grow freely. The sea breeze does not seem to affect it, and it grows and flowers in the most exposed places where other plants can scarcely live. It is raised from seed grown in pots and then planted out. It does not bear transplanting in an older state.—J. B. S., *Bournemouth*.

— **DEATH OF MRS. RIDGEWAY, MOTHEL RECTORY.**—It may interest many of the readers of the Journal to learn that this venerable lady (I have been told the only remaining daughter of the distinguished Sir Joseph Paxton), at about the scriptural age of threescore and ten, quietly passed away at the residence of her late husband, at the Mothel Rectory, not far from here, on the 8th inst. She had been to the West Indies on a visit to the Governor of Jamaica, Sir Henry and Lady Blake, vainly trying to recover her health, and only recently returned. She was reputed to have all the enthusiasm and love for horticulture which her father did so much to extend and popularise, and my gardening friends at various shows have often told me many anecdotes in illustration.—W. J. MURPHY, *Clonmel*.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of this Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 21st inst., at 7 P.M., the following papers will be read:—"Rainfall of the Globe—Comparative, Chronological," by W. B. Tripp, M.Inst.C.E., F.R.Met.Soc. "Mutual Influence of two Pressure Plates upon each other, and Comparison of the Pressures upon Small and Large Plates," by W. H. Dines, B.A., F.R.Met.Soc. "On the Variations of Pressure Caused by the Wind Blowing Across the Mouth of a Tube," by W. H. Dines, B.A., F.R.Met.Soc.

— **PARIS GREEN AND CATERPILLARS.**—Mr. S. H. Stott writes that in making experiments with Paris green some of the poison entered his hand through small wounds that had been caused by pruning Roses. He advises that it should not be handled without gloves for avoiding similar accidents. He is making further experiments with a view to its safe distribution. We may remind our readers that Paris green is prepared in the form of paste, and this Miss Ormerod recommends; it is also preferred to the powder at Toddington, where it has been successfully used in the extensive fruit plantations of Lord Sudeley.

— **THE WEATHER IN NOTTINGHAMSHIRE.**—The following summary of meteorological observations at Hodsock Priory, Worksop, for April, has been sent by Mr. Joseph Mallender:—"Mean temperature of the month, 43·8°; maximum on the 30th, 65·1°; minimum on the 1st, 24·8°; maximum in sun on the 30th, 121·4°; minimum on grass on 2nd and 11th, 17·1°; mean temperature of the air at 9 A.M., 45·7°; mean temperature of the soil 1 foot deep, 45·3°; nights below 32° in shade, eleven; on grass, twenty. Sunshine.—Total duration in month 129 hours, or 31 per cent. of possible duration; five sunless days. Total rainfall, 0·46 inch; rain fell on thirteen days. Wind.—Average velocity 9·5 miles per hour; velocity exceeded 400 miles on six days, and fell short of 100 miles on six days. A fine dry month with a good deal of frost at nights. Vegetation did not grow much during the month, and rain was much wanted at the end."

— **THE RATING OF ORCHARDS.**—Mr. Hobhouse has introduced a short Bill into Parliament, the purpose of which is "To amend the law relating to the rating of orchards for sanitary purposes." In the Public Health Act of 1875 it is provided that "the occupier of any land used as arable, meadow, or pasture ground only, or as woodlands, market gardens, or nursery ground," shall be assessed to the general district rate in an urban district, or to a separate rate levied within the meaning of the Act named in the proportion of one-fourth part only of the net annual value or rateable value of such land. Doubts have arisen whether orchards are included in this provision, and some are accordingly rated at one-fourth, while others are rated at their full value. To remedy this Mr. Hobhouse's Bill expressly provides for the insertion of the word "orchard" after the word "woodlands" in the above quotation, thus placing them upon the same scale as other land cultivated for profit.

— **THE SPARROW PEST.**—Having taken much interest in the communications which have appeared in the Journal recently respecting the destruction of fruit buds by several kinds of small birds, I wish to add my testimony respecting the supposed harmlessness of the common house sparrow. I can sorrowfully inform the readers of the Journal that the last two seasons the sparrows have alighted upon the Red Currant bushes here, piped to each other, and denuded the shoots of every bud within their reach, from the base upwards, excepting the terminal one. I have watched them particularly, and I feel quite satisfied that it is their mischievousness, as plenty of food is available close by. The bullfinches have also done us much damage with the bush fruits and several varieties of Pears, especially the Jargonelle, Beurré Clairgeau, &c., as they are fond of these. The tomtit tribe really do good by picking out the insects, which I have noticed frequently. I wish to thank Mr. J. Hiam for his kindly hints respecting taking bullfinches by

trap cages. I did this and caught several, selling them at 1s. 3d. each. I kept them a fortnight according to his directions.—J. T. EBBUTT.

— **OUTDOOR MUSHROOM GROWING.**—In the Journal of May 8th, at page 381, your correspondent "D. S. H." writes of successful outdoor culture at King's Heath, near Birmingham. I have recently had an opportunity of inspecting some large outdoor pyramidal formed beds in Mr. James Murdock's extensive market gardens at Crewe, close by Kenilworth, and there Mushrooms are grown on an extensive scale both indoors and out. The outdoor beds are made up as recommended in Mr. Wright's treatise, spawned in the winter, covered with litter, and cutting has been going on for some time, from a very heavy crop. This method of growing Mushrooms is so simple and inexpensive as to be within the reach of all. A well made bed lasts in bearing for a long time, and the exhausted manure and soil of the beds is useful for surfacing, especially for heavy soils. Barns, well built but unused pigstyes, and any description of outdoor building is utilised at Crewe for Mushroom growing, even an old silo of considerable size doing duty, and one had to keep toes straight forward to avoid kicking the Mushrooms over, so narrow are the paths. Everywhere are shoals of Mushrooms without any artificial heat whatever, and grown in an inexpensive manner.—W. D.

— **EARLY TOMATOES.**—Kenilworth bids fair to become as celebrated for early Tomatoes, Cucumbers, Mushrooms, and Strawberries as for its grand old castle ruins and excavations at the churchyard, which is laying bare some superb work of past ages. Mr. Henry Whateley has two large blocks of glass structures in Spring Lane, each consisting of ten houses, and each house 103 feet long by 12 feet wide, and the height 6 feet to the apex. They are really Covent Garden supply houses, a style well known to London growers. One block is devoted at present to Cucumbers, from which many thousands of fruits have, and still will be, cut, the varieties grown being Whateley's Hybrid, an excellent variety raised by Mr. Whateley, sen., of Stoneleigh; and a seedling variety of handsome form. Both are heavy croppers. The other block of ten houses are devoted entirely to Tomatoes, each house containing 550 plants in treble rows on each side of the pathway. The sorts grown are the Glamorgan, which is evidently a selection from the 'Old Large Red'; Hackwood Park, but chiefly an excellent stock of the Old Large Red. The plants are very strong and vigorous (my visit was late in April), as high as they will be allowed to go, stopped, and loaded with fruit and flowers, many of the former ready for colouring. They are the finest cropped plants I have ever seen at the period of the year I have mentioned. In one house Ham Green Favourite is planted on one side, the selected Old Large Red on the other, and the latter will, I think, win in a canter for earliness. For cropping the test will be later on, as this house was planted later than the others. They are planted out in old Mushroom beds and soil, plenty of good loam on the grounds, and some excellent Mushrooms are gathered amongst the Tomato plants.—W. D.

— **FRUIT PROSPECTS.**—Peaches and Nectarines on unprotected walls are a good average crop, but have been much infested with green and black fly, and several blistered leaves on some of the trees. This no doubt is owing to the cold north-easterly winds, but now we have had showers of rain, nearly an inch in two days, and warmer weather, the trees will grow freely. Apples, according to present appearance, will be a good average crop. Blenheim Pippin and Keswick Codlin on old trees, and all the Codlin type, are wonderfully prolific in blossom, but it does not always follow where there is so much blossom there is fruit in proportion. The following varieties are showing fairly well on bush trees:—Jolly Beggar, Court Pendu Plat, Kerry Pippin, Northern Greening, Dumelow's Seedling, Devonshire Quarrenden, King of the Pippins, New Northern Greening, New Hawthornden, Worcester Pearmain, Adams' Pearmain, Cellini, Cox's Orange Pippin and Ribston Pippin, a good deal cankered. Laxton's Schoolmaster is showing well on small bush trees. Pears are not so fruitful. The following are the best:—Louise Bonne of Jersey, Williams' Bon Chrétien, Comte de Lamy, Bergamotte Esperen, Beurré de Capiaumont, and Catillae. These are bush trees. On wall, east aspect:—Forelle or Trout Pear, Louise Bonne of Jersey, Williams' Bon Chrétien, and Glou Morceau appear to have set fairly well; but the same varieties on bush trees seem to have suffered from the late sharp frosts. Plums are very thin. This in many instances is caused by the ravages of bullfinches and other birds. Small fruits, including Gooseberries, Currants, and Strawberries, are fairly good. Gooseberries are very clean and healthy. Laxton's Noble is leading the way in Strawberries; it is the first to come into bloom, and is the earliest variety we have for outdoor work.—G. R. ALLIS, *Biggleswade*.

— **THE ROYAL BOTANIC SOCIETY** has arranged for a "Floral Parade and Feast of Flowers" to be held in the Regent's Park Gardens on June 26th next, in the same place as that held last year. The schedule states that—"The idea of the Floral Parade is to encourage the use of floral decorations as in the South of Europe, in public and family rejoicings, such as public festivals, weddings, majorities, and processions. Memorial, funereal, or political indications or suggestions will not be allowed. It is to be distinctly understood that all decorations, dresses, &c., are for out-of-door use. Carriages, &c., can be dressed before entering or in the gardens. The parade will pass the Royal dais, then round the course. The awards will be presented at the Royal dais. Prizes are offered for flower-dressed carriages, horses, pony carts and cars, riding horses, children's carriages, &c., designs and groups of plants and flowers. The classes are as follows:—Victoria or other carriage and pair of horses, all dressed in natural flowers; ditto, ditto, all dressed in Roses; Victoria or other carriage and one horse, all dressed in natural flowers; ditto, ditto, all dressed in Roses; pony basket or car and pony, all dressed in natural flowers; carriage dressed inside as a bower, drawn by one or two horses, also dressed in flowers; riding horse, decorated with flowers; children's pony or donkey, ditto; other carriage or conveyance not included in above drawn by horse or other animal, decorated with flowers; carriage or conveyance moved by man, woman, or child, decorated with flowers; children's mail cart, decorated with flowers; tricycle, decorated with flowers; design or garden in cut and pot flowers; group of Roses, all kinds and colours; climbing plants; specially scented plants; Palms; group of foliage plants, not including Crotons; Crotons; Ferns; variegated hardy plants, Ivies, &c.; hardy cut flowers; standing basket of flowers. Medals are offered in the classes, and for the best of all exhibits a prize of £20.

ODONTOGLOSSUMS AND THEIR CULTIVATION.

[A paper read before the Birmingham Gardeners Mutual Improvement Society at the Midland Institute, March 18th, 1890, by Mr. W. Stevens, Walton Grange Gardens, Stone, Staffordshire.]

ODONTOGLOSSUMS form such a large genus, to which so many additions have been made in the last few years, that they include at the present time some of the most beautiful and useful decorative plants in cultivation. They are all evergreen, producing their flower spikes from the base of the last made pseudo-bulb. Some have large stout pseudo-bulbs and foliage, some small and narrow, the spike usually being produced from the largest sheathing leaf in the shape of spike or panicle. Sometimes two are produced, one on each side, and on strong plants I have even seen three, one on each side and one from the top of the pseudo-bulb. Most of them grow well and flower freely, although there are a few exceptions. *O. coronarium*, for instance, grows well with me, but seldom flowers, or at least not with any regularity.

Then, again, others produce their flower spikes from the matured pseudo-bulb, others come up with the growth, and make the pseudo-bulb at the same time, *O. naviam majus* for instance; and again some flower out of the young growth when about an inch long, *O. citrosium* being an instance. Some produce spikes 3 to 4 feet long, while others only as many inches. Some flower only in the spring, summer, or autumn, but the most beautiful and popular—*i.e.*, *O. crispum* and *O. Pescatorei*—produce them all the year round, and where numbers of these two beautiful species are grown the houses are seldom or never without a few spikes of bloom.

Before proceeding to discuss the cultivation of *Odontoglossums* it will help us very much if we just have a glance at the climate and district from which most of the *Odontoglossums* are collected, and by the kindness of Messrs. Veitch of Chelsea, who have given me the permission to quote from their "Manual of Orchidaceous Plants," part I, I think we shall be able to form a pretty good idea of both climate and district.

The *Odontoglossums* are confined to the mountain region of tropical America that extends from about lat. 15° S. to lat. 2° N. They are also restricted to particular mountain chains within these limits, so that while spreading to an immense distance in one direction, they are included within a comparatively narrow space on the other. Their southern limit is where the great Cordilleras of the Andes begin to draw closer together after enclosing the lofty plateau of Peru and Bolivia, and where a change in the climatic condition of the Andean region becomes perceptible.

From Cuzco northwards as far as Chachapojas, a distance of over 500 miles, the *Odontoglossums* occur very sparingly, only three or four of the small flowered species having yet been met with, but at the last-named place they begin to appear at much smaller intervals. North of the equator the Andes break into three distinct ranges; one, the eastern Cordillera, running in a north-easterly direction, bends along the coast of Venezuela as far as Cape Paria. It is on this range that the greater part of the most popular kinds occur, being most numerous and abundant on that portion that lies between Bogota and Ocaña, and which may be regarded as an *Odontoglossum* centre. The middle

range, called the Central Cordillera, extends northwards, and terminates at Cape Gallinas. Only a few species inhabit this region, but the valleys on both sides, that of the Magdalena on the east and the Cauca on the west, are exceptionally rich in orchidaceous plants.

The third range, or Western Cordillera, has its trend near the Pacific coast, continues its course through the Isthmus of Panama, and onwards to the high table land of Mexico. No *Odontoglossums* are reported from this range within the new Granadian territory or from the Isthmus itself, where the lowest summit level between the oceans on each side of it is probably not greater than 150 feet, but northward of this the land again rises, forming at places peaks of great altitude, and here the *Odontoglossums* again appear.

Throughout Central America there extends a series of table lands, which gradually increase in elevation as the distance between the seas increases, till the great wedge-shaped plateau of Mexico is reached, the average elevation of which is not less than 7000 to 8000 feet. On these elevated lands the *Odontoglossums* occur at first sparingly, but gradually increasing in numbers on advancing northwards towards Oaxaca, where they appear to attain their greatest northern development, beyond which they again diminish in numbers till their northern limit is reached, at about the twentieth parallel.

Not far from this line is the southern limit of the Sierra Madre, where *O. maxillare* has its home; and eastwards from this is the Irapean range, on which *O. maculatum* and *O. Cervantesi* were discovered nearly a century ago by the veteran orchidologist Laxara. These are the most northern *Odontoglossums* known.

Not only are the *Odontoglossums* confined to the mountain chains and table lands above described, but they are also restricted with few exceptions to a zone whose vertical range is confined within comparatively narrow limits. On the South American continent, from the southern limits of the genus to as far as the Isthmus, by far the greatest number occur within a zone whose vertical range rarely descends below 5000 feet, or ascends above 9000 feet. There are some species indeed, such as *O. densiflorum* and *O. compactum*, and a few other small-flowered species which grow on rocks or on the bare ground above the timber line to as high as 11,000 to 12,000 feet elevation.

The climate of this zone, by reason of its elevation, is decidedly temperate, the mean annual temperature being about 57° F. for the higher portion, and 65° F. for the lower; but the difference between the maximum and minimum temperature observed during the year is very great, the thermometer sometimes standing at 90°, and even higher when the sun is vertical, and descending to 40° in the night. The atmosphere of this elevated region is always at a very high degree of saturation, caused chiefly by the north-east trade wind, by which the enormous evaporation from the Atlantic Ocean is constantly being drifted towards the Cordilleras, where it is arrested and condensed.

The rainy season of parts of the *Odontoglossum* region is thus almost continuous throughout the year. At night, when the temperature falls considerably below the mean, the vapour with which the atmosphere is always charged takes the form of a dense fog, which always leaves a copious deposit of dew before being dispersed by the rising day temperature. As a consequence of these climatic conditions the vegetation of this region is uninterrupted throughout the year, and the whole belt is covered with a dense forest.

The *Odontoglossums* are found in the greatest abundance in those parts of the forest which skirt the occasional openings, and along the numerous streams where there is freer access of light and air, and where it not unfrequently happens that numbers of plants are found fully exposed to the direct rays of the sun. It is observed of these that the pseudo-bulbs are always smaller than those which are in partially shaded situations, while those growing in more complete shade, on fallen trees, or on the ground where there is an excess of moisture have large fleshy pseudo-bulbs, rarely flower, suffer much by removal, and generally perish during transmission to Europe.

North of the Isthmus, and especially within the Mexican territory, the local circumstances are somewhat different from those of New Granada, caused chiefly by the peculiar configuration of the land. Here the *Odontoglossums* appear to be spread generally over those portions of the plateau wherever the conditions suitable to their well-being exist, as well as the slopes of the central mountain ranges, and the various spurs that branch from them. The climatic conditions of the *Odontoglossum* region north of the Isthmus of Panama are also somewhat different from the region of New Granada and Venezuela; thus in Guatemala there is a wet and dry season, the first commencing in December and ending in April, and the second (dry) lasting through the remainder of the year, thus there is a decidedly pronounced rest in the vegetation of the country; but on the higher grounds, where the *Odontoglossums* have their homes, there is always a high degree of saturation in the atmosphere even in the dry season, caused by the moisture from the Atlantic and the lowlands being drifted thither by the trade wind, and which during the nights in the early part of the year takes the form of dense fogs. In Mexico the climatic conditions of the Sierra Fria are similar to those of the highlands of Guatemala, but the rainy season is of shorter duration, and the temperature is remarkably uniform, the mean summer and winter temperature varying scarcely more than from 10° to 12°. The precipitation caused by the trade wind attains its greatest strength on the eastern slopes of the mountains skirting the high central table land; here the rainy season lasts eight months of the year, and the temperature ranges between 53° to 60° F.

Throughout the whole of the *Odontoglossum* region there is never a

perfect rest; in the aerial currents there is always a gentle breeze to be noted.

(To be continued.)

THE ROYAL HORTICULTURAL SOCIETY.

THE schedule issued for the Society's Show in the Inner Temple Gardens, May 28th and 29th, states that "silver cups and medals will be awarded according to merit for exhibits in the following classes:— A, Flowering plants: Orchids, Anthuriums, Azaleas (Indian and Mollis), Begonias, Calceolarias, Roses, Rhododendrons, Gloxinias, Alpines, Clematises, Pelargoniums, &c. B, Foliage plants: Palms, Ferns, new Plants, Dracænas, Caladiums. C, Cut flowers: hardy herbaceous plants, Rhododendrons, Tulips, Lilies, Irises, Roses. D, Miscellaneous Groups (flower and foliage). E, Market plants. F, Bouquets, table decorations, &c. G, Fruit. H, Vegetables. The Society will issue for this Show a catalogue comprising a history of the Royal Horticultural Society, including particulars of their meetings and shows both at the Drill Hall, James Street, S.W., and at Chiswick. It will contain the programme of the music to be performed each day by the band of Her Majesty's Royal Horse Guards (Blues), and a list of exhibitors and of their chief exhibits; but we are requested to state that no names, &c., can possibly be inserted unless they are received by Mr. Barron, R.H.S. Gardens, Chiswick, or at the Society's offices, 117, Victoria Street, on Saturday, May 24th, at the latest; 10,000 of the schedules are being printed in expectation of the Prince of Wales opening the Show."

As the position is the best to be found in London we shall hope for favourable weather and a brilliant success.

We have received the following letter for publication:—

DEAR MR. EDITOR,—With regard to a report which has appeared in a contemporary of my resignation of the secretaryship of the Royal Horticultural Society, may I ask you to be so kind as to contradict it? The report, however, has somewhat more truth in it than have most reports, for I am very anxious to find someone who will take up the work. The Society may, I think, now be said to have turned the corner, and has, I hope, seen its worst days. I feel, therefore, that I have done my duty by the Society, and that I could now hand things over to a successor in a far more satisfactory condition than I found them. A new era, too, is commencing, with the prospect of a new hall, and therefore it seems to me a most fitting time for a new shoulder to be put to the wheel. At the same time, though on many accounts I am very desirous of retiring into private horticultural life, I have not actually resigned, nor shall I do so until a successor is forthcoming unless more urgent reasons arise than I am glad to say at present exist.—W. WILKS.

Mr. Wilks has laboured incessantly in the interests of the Society, and won the esteem of a host of friends. The value of his services are fully, and we believe unanimously, appreciated. We should rejoice to see him retain the honourable, if exacting, position he holds till the new Hall is an accomplished fact. We have done our best to make clear the conditions of co-operation. We are convinced that Baron Schröder's project is absolutely safe, and the sums contributed—be they large or small—will be repaid to the uttermost farthing. It is a question of sacrificing the interest on the amount subscribed, and that alone, for a time in the interests of horticulture. We are glad to find from a list before us that additional promises of support are recorded, and we earnestly hope that all connected with the industry of horticulture who are in a position to help forward the project will do so, and that amateurs with means at their disposal will not hesitate to enrol themselves as supporters.

SPARROWS AND RATS.

It seems to be now pretty generally acknowledged that sparrows have become an actual pest to the farmer and gardener, but it is odd how differently they behave in different places. I have never had any Primroses or Crocuses injured by them, but a neighbour who lived less than a mile away (and each of us adjoined a farmyard where sparrows swarmed), had to protect these flowers most carefully, or every bloom would be plucked off as soon as it opened. The only garden produce of mine which they injure is Peas. These are easily protected by dark thread when in the ground or just coming up, but it is a nuisance to have to net them when in pod. The families of young birds just able to fly give the most trouble at that time.

There is no doubt they are very destructive. The worst injury they do, as I have before pointed out in the Journal, being the driving away of martins, which are naturally appointed to keep down hurtful insects by destroying them in the air in their winged breeding state. And I quite agree with Mr. A. T. Marston that "Nature herself provides the requisite balance in all things," and that an undue increase, amounting sometimes to a pest, arises when that balance is interfered with. But

I cannot think that in this case the injury has been done by the destruction of hawks. Sparrows constantly hanging about houses are pretty well protected from birds of prey, and if hawks abounded in sufficient numbers to keep down sparrows we might have the Green Peas perhaps, but very few young ducks and chickens, I fear, to eat with them. No; the balance of Nature has been interfered with in their favour by the artificial housing and feeding of sparrows. We provide them in our houses, our Ivy, and our barns, &c., with comfortable roosting and nesting places, and we feed them in winter by allowing them access to the food supplied to animals and fowls. And the fault lies, I think, in the apathy with which farmers, and perhaps others, view what seems to them to be small matters, and to some extent in a sentimental feeling, excellent in itself, against destroying nests with old birds and eggs or young together. It seems rather strange that a farmer should complain and "write to the papers," and employ boys with guns to scare the sparrows from his corn, when he has quietly allowed them to breed by scores during the spring and summer all over his premises, pulling about and spoiling his thatch before his very eyes; but it is so.

I was present the other day at the threshing of a Wheat stack where there were very few rats but hundreds, perhaps thousands, of mice, though white and brown owls breed within half a mile. Neither the farmer or his men took much heed of them, or seriously attempted to destroy them, though showers of chaff, attesting the damage done, poured from every sheaf lifted. They escaped by scores into the straw, though my boys killed some hundreds. And are there not a good many farmers who look upon rats as small matters, not worth the trouble of destroying unless they make a really great show? I was walking with an old gamekeeper a good many years ago by a stack and hedgeside where the presence of a good many rats was very evident, and on my saying what a pity it was to let them do so much harm, he answered, "Harm, sir? Oh, no! Dear little things! they don't do any harm, bless you, not they! while a poor innocent rabbit, sir," &c., &c. He "spoke in bitter jest," and also, of course, to a large extent in party spirit; but while fully recognising the great injury rabbits are capable of doing, I could not help thinking that he had some cause for his "chaff," and I was, and am, surprised that farmers take so little trouble to utterly destroy rats. To this desirable end I believe there to be only one royal road, and that is, first, to employ a professional ratcatcher, and, secondly, to pay him on the same principle on which the Emperor of China is said to pay his physician: while the emperor is well, the physician gets a fair salary; when he is ill, off comes the doctor's pay; and when he dies, off comes the doctor's head. Pay the ratcatcher a very small but regular salary as long as there are no rats, and stop it on the first appearance of a rat till it is caught.

In the destruction of rats and rabbits there is one individual that is far more desirable and difficult to catch than the others, and that is the last one. By the present system of paying ratcatchers the very rat you want to get is the one he wants to keep alive; by the other system he would be as anxious for it as you are, as it would be the only one he would get anything for. Of course, it would be desirable, if not necessary, for occupiers to combine over a considerable area. One man would then eventually have charge of a large district for a very small fee from each occupier, which would act as a kind of insurance against rats.

I hope we shall not have to come to this with sparrows; but at any rate every gardener may seriously lessen his own injury by regularly and properly looking after the nests. With a little care and practice the hen bird may generally be caught on the nest at night, and though this sounds cruel, it is surely not so bad as the use of poison, which would cause the young to die of starvation.—W. R. RAILLEN.

with darker veins, the sepals and lower petals being ivory white. The unfolded lobes of the lip are white beautifully spotted with bright rose, and this gives a peculiarly distinct and pleasing appearance to the flower.

This grand hybrid was named in honour of the Baroness Schröder, and in the collection at The Dell Gardens a fine specimen is grown, which has been shown on several occasions in first-rate condition.

FIG. 60.—CYPRIPEDIUM SCHRÖDERÆ.

CYPRIPEDIUM SCHRÖDERÆ.

SEVERAL handsome hybrids have been obtained in what is often termed the Sedeni section of Cypripediums, but that of which a flower is depicted in fig. 60—obligingly lent by Messrs. J. Veitch and Sons, Chelsea—is one of the best and most distinct. It resulted from a cross between *C. caudatum* and *C. Sedeni*, effected by Mr. Seden in the Chelsea nurseries, and presents an interesting combination of characters, while surpassing both in floral attractions. The flowers are large, being fully 4 inches from the apex of the dorsal sepal to the base of the lip, the petals being 4 to 6 inches long, half an inch broad at the base, tapering and twisting to the points. The colour is rich rose, is strongly marked in the fine rounded lip; a similar tint but slightly lighter is seen in the petals

PROGRESS WITH VEGETABLES.

PART 1 of vol. xii. of "The Journal of the Royal Horticultural Society" recently issued forms a volume of 232 pages. It contains the papers read at the Vegetable Conference and the Chrysanthemum Centenary Conference last year, together with reports of the Society's Committee meetings and list of plants certificated. Under the Chrysanthemum report the returns from eighty-seven voters have been tabulated by Mr. Molynaux, and lists of varieties suitable for different purposes are thus furnished.

From the report of the Vegetable Conference we extract the following remarks by the Chairman, Mr. H. J. Veitch, at the opening of the Conference, and dealing with the progress in vegetables.

While decorative plants and flowers, in all their varied forms and

brilliant and delicate colours, must necessarily form the most striking part of a horticultural exhibition, and also the chief attraction for the general public, it cannot be otherwise that the homely aspect of the vegetables in daily use should cause them to fall into a subordinate place as objects for exhibition to the majority of the visitors. To the gardener, however, they have a different significance, and often a deeper interest attached to them than the more showy products of the flower garden. In fact it is not too much to say that an exhibition of vegetables like the present one is essentially a gardener's exhibition.

There are some simple facts connected with the present state of development of our most commonly cultivated vegetables that are worth bearing in mind. One of the most prominent of these facts is the length of time that it has taken since these plants were first reclaimed from the wild state to attain the perfection in which we now have them. Scarcely a vegetable in daily use can be named that has not been in gardens for centuries. The Runner Bean, the Tomato, and the Vegetable Marrow were probably among the latest to come into general cultivation, and these were as familiar to our great-grandfathers as they are to us, although in a lower degree of perfection and productiveness. The Cabbage is one of the most ancient of vegetables, for we know that it was cultivated by the Greeks and Romans, and it has therefore been in cultivation as an article of food for more than 2000 years in the south of Europe generally, and following the spread of civilisation into more northern latitudes. In a wild state the Cabbage has been observed to deviate a little from a common type, but under the care of man, in such a variety of climate and soil in which it has been cultivated during so many centuries, it has broken into the various forms we now have it, these forms including the Broccoli, Cauliflower, Brussels Sprouts, Savoy, Kales, and Borecole, besides all the varieties known in gardens as Cabbage; and yet it is an accepted theory, I may say a positive belief, held by botanists, that all these various forms have originated from a single herb still to be found wild in places on our own coast, and somewhat more plentifully on the neighbouring coast of France. This plant is the *Brassica oleracea* of science, and is, I daresay, known to many of you. When we contemplate this seaside herb in comparison with its descendants in our gardens, the results brought about by cultivation are truly astonishing; but the surprise must be modified by the reflection on the length of time it has taken to accomplish them.

Let me quote another instance. The Potato was introduced from America three centuries ago, and has been generally cultivated for at least 200 years. Quite recently one of our most accomplished botanists, Mr. J. G. Baker of Kew, has investigated the tuber-bearing species of *Solanum*, and has expressed his belief that all the various forms of the cultivated Potato have originated from one species—viz., *Solanum tuberosum*. From these two instances we see plainly how remarkable are the changes brought about by the continuous cultivation of a single species, and at the same time how long a period, extending over many generations of human life, it takes to effect them. We can understand, too, from these same facts how it is that a plant or herb with properties rendering it suitable for food when improved by cultivation is rarely, if ever, taken in hand by horticulturists of the present day.

There are six known species of tuber-bearing *Solanums*, from one of which, *S. tuberosum*, as I said before, all our garden Potatoes have originated. Of the other five there is at least one that promises to be very valuable as the starting point of a new race of Potatoes, which, under the more scientific gardening of the present age, may be made to bring about satisfactory results in a much shorter space of time than it has taken to bring our present race of Potatoes, under the more primitive practice of our forefathers, to the perfection in which we have them. This is *Solanum Maglia*. I will quote Mr. Baker's words from the "Journal of the Linnean Society," vol. xx., page 507:—"As far as climate is concerned, it cannot be doubted that *Solanum Maglia* (or the Darwin Potato, as we might suitably christen it in England) would be better fitted to succeed in England and Ireland than *S. tuberosum*, a plant of a comparatively dry climate. We have indisputable testimony that *S. Maglia* and *S. Commersoni* yield readily an abundant supply of eatable Potatoes. What I would suggest is that these should be brought into the economic arena and thoroughly tested as regards their economic value, both as distinct types and when hybridised with the numerous *S. tuberosum* forms." It is very gratifying to know that the Messrs. Sutton of Reading are already busy in this direction.

The vegetables of the immediate future may possibly include the tubers of a Chinese species of *Stachys* (*S. tuberifera*) which was put into commerce two or three years ago by MM. Vilmorin et Cie. of Paris. The tubers have an agreeable flavour peculiar to themselves, but seem to require a few years of assiduous cultivation to develop them into a sufficient size to afford a remunerative crop.

This being the first time such a meeting as the present, with such an object, has been held, I hope you will agree with me that a brief review of our present position will not be out of place. Let us now, therefore, carry back our recollections of vegetable culture twenty-five to thirty years, a period still fresh in the memory of many of you, and try to ascertain approximately what progress has been made during that period, and in what direction it has chiefly tended. The garden vegetables cultivated a quarter of a century ago were much the same as now as regards kinds, and the comparison can thence be made without the introduction of any new element.

To begin with Peas. As the improvement obtained among these during the period in question will be the subject of a special paper, I

need only take a general review of the progress achieved. The varieties of Peas in commerce from twenty-five to thirty years ago were probably as numerous as at the present time. During the interval an uninterrupted stream of novelties have been offered to the public year after year, and during the same time upwards of a hundred names have disappeared from catalogues. Of the new varieties brought into cultivation in the period under review forty-two have been awarded first-class certificates by the Royal Horticultural Society, after having been grown in the comparative trials in the Society's garden, and most of these were subsequently put into commerce, but eight or ten of them have already disappeared. Besides these, a large number of new, or so-called new, varieties have been sent out without having been submitted to the test of the Chiswick trials; and, although some are acquisitions, many of them soon passed into oblivion, or were found to be synonymous with other sorts. Many of the older sorts, however, still hold their place; among such are notably Champion of England, Veitch's Perfection, Ne Plus Ultra, and British Queen—for quality and general usefulness these are difficult to beat; whilst we find such varieties as Early Emperor, Early Charlton, White and Blue Prussians, Waterloo tall Marrows, and others that could be named, which were once standard varieties and most largely grown, are now happily almost entirely superseded by the later acquisitions.

Under the general name of Brassica is included Cabbage, Broccoli, Cauliflower, Kale or Borecole, Brussels Sprouts, Savoy, a series of vegetables of the highest importance as furnishing a supply throughout the year. A review of what has been done in the way of improvement during the past quarter of a century must, however, be brief, taking them in the order named. Upwards of fifty names of Cabbage in seed lists thirty years ago are not now found there, and perhaps deservedly; but yet very few real acquisitions have been made since. Ellam's Dwarf Early Spring, certificated in 1884; Early Etampes and other varieties of French origin, valuable for spring sowing and main crops; and Early Offenham, a fine example of the old Enfield type, are all of comparatively recent introduction. The Broccoli family has always been a numerous one; as many as forty-five names have been noted in a seed catalogue published at the beginning of the period under review, but all are now lost to fame. Their place has, however, been taken by perhaps more than that number of new names, their greatest merit being the lengthening of the season. I must mention here the Cabbage-Broccoli called Chou de Burghley, raised and distributed by Mr. Gilbert of Burghley Gardens; and also the new form of sprouting Cabbage raised by Mr. McIndoe of Hutton Hall, both of which indicate a new departure. Among the newer Cauliflowers, the Autumn Giant, certificated in 1870, has stood the test of time, and is now an established favourite both in gardens and for market purposes; its introduction prolonged the season very considerably, while the Extra Early, certificated in 1880, has lengthened the season in the opposite direction by being grown in frames or under hand-glasses. Kales are not much appreciated south of the Tweed, although, after a severe winter, they may be relied on when everything else is crippled. Many selections have been offered during the past quarter of a century, but none much in advance of the old Green Curled. In Brussels Sprouts, on the contrary, a marked improvement has been made; but the Savoy has remained much as it was, with the addition of Early Dwarf Vienna, and Gilbert's Universal, certificated in 1884.

Among Beans not much has been done in the way of improvement. We still cultivate the same varieties of Dwarf French Beans as we did twenty-five years ago. Ne Plus Ultra among the early sorts, and Canadian Wonder among the long-podded late sorts, are the best introductions of late years; and among Runner Beans, Girtford Giant and The Czar, which were raised by Laxton, are the most prominent improvements. The French varieties of Butter Beans are, I think, deserving of more attention than they have hitherto received; as served in France they are certainly a great delicacy. Some of the old sorts of Broad Beans, as White Blossom, Red Blossom, and others, have nearly disappeared. Beck's Green Gem may be considered an improvement on the old Dwarf Fan; Seville Long-pod and Aquadulce, introductions from Spain, have certainly the advantage of producing very long pods, but it is doubtful whether they have so many beans in a pod as a well-selected stock of Hang-downs, of which Bunyard's new selection is perhaps the best.

After dealing with Potatoes, Mr. Veitch proceeded:—Turning to tap-root vegetables, we find that thirty years ago only three varieties of Beet were generally cultivated. Dell's Crimson, introduced in 1869, has, under many synonyms, taken the place of most of the older forms, while the Egyptian Turnip-rooted has been a welcome addition to the sorts for early use. Among Carrots the old sorts are still more or less cultivated, but selections from some of the French varieties, such as the Early Nantes, Guérande, and St. Valéry, are now extensively grown. One peculiarity in some of the newer sorts should be noted—they are of a uniform bright red colour throughout, and destitute of the yellow core so familiar in the older kinds. Generally speaking, the improvement in Carrots has tended towards the production of earlier varieties, better shape, better quality, and greater weight of crop. The Parsnip being of so much more restricted use, naturally falls into a subordinate place, and the old sorts still hold their sway.

The season for garden Turnips has commenced earlier by the introduction in 1883 of the Extra Early Milan, which comes into use from ten to fourteen days before any other sort. Many of the old kinds of Onions are still the best, but among more recent and desirable varieties I may

mention the Rousham Park, the Queen, the Roccas and other Italian Onions, all useful introductions and much in demand of late years.

The Vegetable Marrow, one of the most popular and cheapest of vegetables when in season, has received at least two useful additions of late to the number of its varieties in Pen-y-Byd (the best in the world), raised by Mr. Muir, of Margam Park, Glamorganshire, a small round-fruited sort, and Hibbert's Prolific, a small egg-shaped variety. One of the first to improve the vegetable was the late Mr. Thomas Moore, of the Chelsea Botanic Garden, who raised Vegetable Cream.

A few other kinds of vegetables have yet to be noticed which, on account of some special requirements in their culture, are still restricted to gardens in which these necessary requirements can be provided, or can be grown on a large scale for market. Among these the fine form of Seakale called Lily White is an improvement both in colour and flavour on the old form with purple colouring. The Tomato is yearly increasing in popularity, and receives a corresponding increase of attention from cultivators; its season has been extended to almost throughout the year. Thirty years ago not more than four or five varieties appeared in seed lists, but now the enumeration of them fills well-nigh a whole page of some catalogues; without referring to any of them by name, the best of them are undoubtedly in advance of such old sorts as De Laye, Powell's Prolific, &c. The cultivation of the Mushroom has increased enormously of late years; it is perhaps no exaggeration to say that, for every pound produced by cultivation thirty years ago, upwards of a ton is so grown now.

I will take but a glance at the progress made in Saladings. In Lettuce, during the period under review, a multitude of varietal names have appeared and almost as rapidly disappeared. In the Cabbage Lettuce section the kind known as All the Year Round has proved a useful introduction, and retains its place as one of the best. Early Paris Market is one of the best early kinds, and is much cultivated. In the Cos section, Paris White, Hicks, Hardy White, and Bath Cos are among the most useful. In Celery, too, the list of names constantly increases, so that selection sometimes becomes difficult. Of the red varieties, Major Clarke's is one of the best of recent introduction, and, among the white kinds, Turner's Incomparable White (syn. Sandringham) holds its own. The finest addition to the varieties of Endive is the Improved Brown-leaved Batavian, certificated in 1878; this is by far the best of the broad-leaved forms.

Among Radishes the best improvements come from France; the extra-early Turnip varieties are useful for growing in frames, whilst the white-tipped olive-shaped, or French Breakfast, is one of the most largely grown. Although the Cucumber is properly a fruit, it is practically looked upon as a salad. Here again, as in the case of many other popular vegetables, the multitude of names is bewildering. Rollisson's Telegraph and Douglas's Tender and True are both standard sorts.

MARÉCHAL NIEL ROSE.

I SEND you a few blooms of Maréchal Niel Rose, cut from plants one year old from cuttings, with a brief note as to how such results are obtained.

A deep box (an old tea chest, for instance) is procured, in which are placed 2 inches of drainage, 2 or 3 inches of light soil, with a surfacing of silver sand, and a square of glass to fit closely. Now as to cuttings. They consist of the remaining portion of the flower stalk after the flower has been cut, taken off back to the old wood with a heel, shortened to one or two joints if necessary, but the leaves left intact. They are inserted in the said box, a good watering is given through a fine rose to settle the soil about them. They are covered closely with the square of glass, plunged in the manure of a Melon or Cucumber frame where there is a good bottom heat, and shaded from sun. We occasionally examine them, removing decaying leaves, and giving a sprinkling of warm water.

As soon as rooted they are placed singly into 3-inch pots in a compost of loam, leaf soil, and sand, and returned again to the frame, placing them as far from the point where air is admitted as possible, and shade till established. Then they are gradually inured to cooler treatment and have the benefit of full sunshine. As soon as the pots are filled with roots the plants are shifted into 6-inch and finally into 8-inch pots, which will well accommodate them to flower in, using a mixture of good strong loam, old mortar rubbish, and a small portion of leaf-soil rammed into the pots.

The treatment here indicated, together with a free use of the syringe, plenty of air, unobstructed light, the judicious use of some fertiliser, and liquid manure occasionally when the pots are filled with roots, will result in good stems capable of giving a score of first rate blooms. One shoot only should be taken up with no stopping whatever, just the unripe point is taken off at the winter pruning, and ours are kept entirely under glass. I may add that from eight

plants grown as here described we are taking 150 blooms.—T. CROSS-WELL, *Homewood, Eden Park, Beckenham.*

[Remarkably fine were the blooms received, substantial, clean, and sweet. The foliage also was most vigorous.]

ROYAL HORTICULTURAL SOCIETY.

MAY 13TH.

A LARGE portion of the Drill Hall at Westminster was filled with plants and flowers at the meeting on Tuesday last, the exhibits being varied in character, and comprising many novelties of interest. At the afternoon meeting Mr. W. Goldring, who has just returned from India, discoursed upon "Spring Flowering Trees and Shrubs" to a large and appreciative audience.

FRUIT COMMITTEE.—Present: Sir Chas. Strickland, Bart. (in the chair), and Messrs. R. D. Blackmore, Harrison Weir, T. Francis Rivers, J. Cheal, W. Bates, G. W. Cummins, T. J. Saltmarsh, G. Bunyard, P. C. M. Veitch, G. Wythes, H. Balderson, F. Q. Lane, and James Hudson. The work of this Committee was extremely light on this occasion, for the exhibits were few, and small space at the end of a table sufficed to hold them. The Right Hon. Lord Foley, Ruxley Lodge, Esher (gardener, Mr. Miller), contributed some fine specimens of Mushrooms, also some Asparagus (vote of thanks). J. Butler, Esq., Warren Wood, Hatfield (gardener, Mr. G. Aslett), sent two dishes of Alexander Peaches, large well coloured fruits (vote of thanks). Mr. E. Chopping, Milton, exhibited specimens of Bugg's Apricot Pippin; Col. T. P. Turberville, Ewenny Priory, Bridgend, showed a green flesh Melon; and from the Society's gardens at Chiswick came a collection of Broccolis. A first-class certificate was awarded for the following:—

Veitch's Model Broccoli (W. C. Leach, Albury Park, Guildford).—A solid white-headed variety of good quality, of moderate size, and well protected with long leaves.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair, and Messrs. R. Dean, B. Wynne, H. Herbst, T. Baines, C. T. Druery, H. B. May, W. C. Leach, G. Mawley, H. Cannell, R. B. Lowe, Lewis Castle, G. Paul, W. Holmes, G. Nicholson, and Rev. D'Ombrian.

Many novelties were submitted to the judgment of this Committee, and a considerable proportion of these had to be passed without any award; indeed, in one or two cases it was surprising that the exhibitors had not exercised more discernment before taking the trouble to bring their "novelties" into public with the expectation of receiving any recognition. From the Royal Gardens, Kew, came an extensive collection of flowering specimens of hardy trees and shrubs, representing many of great beauty, though their attractions cannot be seen to the best advantage in small pieces arranged in bottles or other vessels. Mr. R. Irwin Lynch, Curator Botanic Gardens, Cambridge, also exhibited plants of *Arisæmas*, *Asarums*, and *Aristolochias*, including some very interesting species.

Messrs. J. Veitch & Sons, Chelsea, contributed a small group of *Phyllocactus* varieties and the bright red flowered *Epiphyllum Gaertneri*, but although the former included two excellent varieties, one bright crimson named *Admiration*, and the other a soft rose named *Delicatus*, the Committee did not accord them any special recognition. When plants become unpopular it is very difficult to restore them to favour again, and beautiful as many of the *Phyllocactus* and *Cereus* undoubtedly are, nurserymen and the public look at them with little enthusiasm. Mr. Poupart, Twickenham, sent three large pots of Lilies of the Valley bearing long spikes of flowers (cultural commendation). Messrs. Ryder & Son, Sale, showed a group of Japanese Primulas similar to those at the Crystal Palace on the previous day. Mr. F. Hooper, Bath, exhibited flowers of the large white Pink *Her Majesty* and a collection of Pansies (bronze medal). Mr. R. Dean showed some Alpine Auriculas; Mr. Simpkins, Camberwell, sent a new white Zonal Pelargonium named *Miss F. Measures*; Messrs. H. Cannell & Son, Swanley, exhibited a choice collection of Zonal and Show Pelargoniums with fine Pansies (bronze medal).

Messrs. W. Paul & Son, Waltham Cross, exhibited blooms of a new Hybrid Perpetual Rose named *Denmark*, of similar colour to *La France*, but different in the form of flower and the foliage, and the Committee asked to see it again. Plants of the white Tea Rose *The Queen* and *Souvenir de S. A. Prince* for comparison, and the Committee was asked to express an opinion regarding the identity of the two Roses. This, however, they declined to do, but as they were shown, and compared also with the blooms from Mr. G. Prince of the *Souvenir* there is a strong resemblance between them, and it is possible the National Rose Society will find an opportunity of dealing with them, as they will probably go into the list of too much alike Roses if both names are retained.

Mr. Forbes of Hawick sent a large collection of his best Pansies, for which a bronze medal was awarded. Messrs. Barr & Son had a group of *Daffodils* and hardy flowers (bronze medal).

Messrs. J. Veitch & Sons also had some hardy shrubs and trees, such as *Sedum latifolium*, *Abies excelsa mutabilis*, a new *Cydonia*, and a *Juniper*, for which certificates were awarded. Messrs. Paul & Son, Cheshunt, had a most interesting collection of flowering tree and shrub specimens, *Azaleas*, *Rhododendrons*, and *Lilacs* being well represented (silver medal); and Messrs. Kelway & Son, Laugport, showed numerous boxes of fine *Pæonies* and *Pyrethrums* (silver-gilt medal).

ORCHID COMMITTEE.—Present: Sir Trevor Lawrence, Bart. M.P., in the chair, and Messrs. S. Courtauld, F. Moore, H. J. Veitch.

J. Sander, H. M. Pollett, E. Hill, J. Douglas, H. Williams, H. Ballantine, T. B. Haywood, and C. Pilcher.

An excellent group of plants of *Cypripedium barbatum* came from the Duke of Northumberland (gardener, Mr. Wythes), for which a vote of thanks was accorded, though a medal, or at least a cultural commendation, would have been an appropriate recognition. There were eighteen plants, all well grown, and bearing fine flowers of rich colour. N. N. Sherwood, Esq., Dunedin, Streatham Hill, showed an excellent plant of *Phalenopsis grandiflora* with good blooms, and a deeply coloured *Odontoglossum crispum*. Mrs. Studd, 4, Royal Crescent, Bath, sent a specimen of a variety of *Laelia purpurata* named Studdi. From Sir Trevor Lawrence, Bart, M.P., Dorking, came an example of *Laelia purpurata* Brysiana, the flowers beautifully coloured. R. J. Measures, Esq., Camberwell, showed a fine plant of *Masdevallia ignea* Southgatei having numerous bright orange-red flowers, also a diminutive species, M. O'Brieniana, with small yellowish flowers, and *Cattleya Mendeli* Venus with pale delicate, but charming flowers (vote of thanks.) Mr. James O'Brien exhibited a plant of *Disa tripetaloides* with small, pale mauve-spotted flowers.

G. Burnham, Esq., 17, Paget Road, Stoke Newington, sent plants of *Cymbidium albucaeflorum*, with long spikes of small yellowish green flowers, and *Dendrobium thyrsiflorum*, having ten long racemes. Mr. Lucien Linden, Brussels, exhibited a pure white *Odontoglossum crispum virginalis* (vote of thanks), *Dendrobium Gallicanum*, in the style of *D. thyrsiflorum*, but with longer flowers and looser racemes, and *Cattleya Warocqueana*, which some thought resembled *C. Warneri*. Messrs. Sander & Co., St. Albans, exhibited a plant of a handsome *Odontoglossum excellens*, named Albert Edward (vote of thanks). G. Cooke, Esq., Kingston Hill (gardener, Mr. J. D. Cullimore), had plants of a light coloured *Laelia purpurata*, and a richly tinted *Cattleya Mossiae* (vote of thanks). A. G. Smith, Esq., Silvermere, Cobham (gardener, Mr. J. Quarterman), had a good plant of *Cypripedium barbatum*; H. Balderson, Esq., Hemel Hempstead, showed *Cattleya Warneri*; Sir Chas. Strickland sent *Cattleya citrina* (vote of thanks); and Messrs. Pitcher & Manda, Hextable, showed a collection of hardy *Cypripediums* and other Orchids.

CERTIFICATED PLANTS.

Cytisus scoparius var. *Andreanus* (Sir Trevor Lawrence, G. Paul and Son, and J. Veitch & Sons).—A handsome distinct variety of the common Broom, which has been already shown elsewhere, and certificated under the name of *Genista Andreanus*. With this name it also appeared at the Drill Hall in the collections for the three exhibitors above named, but in the Kew collection it had the name here adopted. It is said to be a variety of the common Broom, and was found wild in Normandy and elsewhere. It was sent out by a French firm, and has appeared in some lists with the name *Genista bicolor*. The flowers are large, bright yellow, with the "alæ" or wings—an easily distinguished portion of a papilionaceous flower—being a rich reddish brown, a striking contrast with the other portion of the flower.

Calla Elliottiana (Mr. G. M. Knight, Farnborough Park).—A remarkable Aroid, with large deep green leaves spotted with white, and a fine rich yellow spathe; a decided advance upon any so-called yellow *Arum* yet exhibited.

Odontoglossum maculatum, dark variety (W. C. Atkinson, Esq., Liverpool).—A variety with large, well formed flowers of an extremely dark colour.

Blandfordia nobilis imperialis (F. Sander & Co.).—A superior form of a handsome plant, the flowers large, drooping and bell shaped, rich orange red and yellow, the leaves long, narrow and grass-like.

Pansy Eynsford Yellow (Messrs. Cannell & Sons).—A good bedding variety with deep yellow flowers of good shape and freely produced (award of merit).

Cydonia japonica var. *Moorlezi* (J. Veitch & Sons).—A variety with large soft red flowers, but chiefly remarkable for its floriferousness and the long period during which it continues flowering.

Juniperus canadensis aurea (J. Veitch & Sons).—A dwarf variety, the young growths tipped yellow.

Pæony Beatrice Kelway (Messrs. Kelway & Son).—A tree *Pæony*, with large white single flowers of a cupped form, and very handsome.

Cælogyne tomentosa (R. J. Meadows, Esq.).—Flowers with narrow sepals and petals of a pale terra cotta tint, borne in long drooping racemes, the plant shown having five of these.

Lunaria biennis variegata (Messrs. Cutbush & Son).—The deep purplish crimson flowers of this plant contrasted strangely with the variegated foliage. Very distinct.

Enkianthus campanulatus (J. Veitch & Sons).—An interesting little shrub of compact habit, with numerous small bell-shaped reddish flowers, like diminutive *Abutilons*.

Acer Prince Hendjery (Paul & Son).—A beautiful variety of the common Sycamore, with bronzy coloured leaves; very attractive at this time of year.

CRYSTAL PALACE SHOW.

MAY 10TH.

THE annual Exhibition of plants at Sydenham in May has acquired considerable fame amongst competitive shows, and at one time constituted an imposing display of the gigantic trained specimens which have astonished so many thousands of visitors. It has been evident, however, for some years that the number of these specimens is gradually being reduced, and this was indicated at the Palace Show on Saturday.

The competition in what are termed the leading classes for specimen plants was restricted to few exhibitors, and even they, with some exceptions, were not showing in their best style. Fortunately, however, in the smaller classes the exhibits and competition were excellent, and though in the general arrangement they were rather too much scattered, yet even that is preferable to undue crowding which too frequently takes place at shows of this character. The Palace is splendidly adapted for large shows, but small ones are lost there, and require concentration to produce a satisfactory effect.

STOVE AND GREENHOUSE PLANTS.—The only nine plants came from Mr. Chapman, The Gardens, Hawkesyard Park, Rugeley, his best specimens being *Erica profusa* in excellent condition and well flowered, *Tremandra ericæfolia* fresh and good, *Anthurium Schertzerianum*, two small *Ixoras*, and *Statice profusa*. An ill-formed *Hedera* and a poorly flowered *Erica Cavendishiana* would have spoiled the collection in a moderate competition. With six plants Mr. Chapman was again first, Mr. Offer, The Gardens, Handcross Park, Crawley, taking the second prize, but neither had any very remarkable plants. Mr. C. Turner, Slough, was the premier exhibitor of *Azaleas*, securing first honours both for eighteen and nine plants, fresh, neat, moderate size plants of a most useful character. Orchids were represented by few plants. Mr. J. Douglas, gardener to Mrs. Whitbourne, Great Gearies, Ilford, was awarded the second prize for nine and the first for six, but they do not call for special description. Mr. Douglas was also first with an ordinary *Dendrobium nobile*, and Mr. W. Finch second with *Lycaste Skinneri* alba bearing two flowers, in the single specimen class. For a single specimen greenhouse plant in flower Mr. Turner was first with *Azalea* Duc de Nassau, very handsome and well flowered, Mr. Chapman following with *Tremandra ericæfolia* also in good condition, the same exhibitor being first with a single stove plant in flower, showing *Ixora* Dixiana.

Roses constituted a pleasing portion of the Exhibition, and the centre transept round the band stand, by the orchestra, and in front of the stage, they had a charming effect. Messrs. W. Paul & Son's non-competing group must have prominent mention here, as it included a number of well-grown plants tastefully arranged, and comprising some choice varieties. In the class for eighteen Roses in pots Mr. C. Rumsey, Waltham Cross, secured premier honours with admirable plants bearing fine blooms, *Beauty of Waltham*, *Thomas Mills*, *Madame Gabriel Luizet*, *Dr. Andry*, and *Centifolia Rosea* being notable. Messrs. Paul & Son, Cheshunt, were second with a collection of nearly equal merit, particularly fresh, and Mr. C. Turner was third with rather smaller but healthy plants. *Pelargoniums* of both show and fancy varieties were chiefly exhibited by Messrs. Turner and Phillips, the prizes being nearly equally shared by them. The plants were in good condition, but the flowers suffered much during the day.

Calceolarias were largely shown, no less than five competing in the class for eighteen plants. Mr. Ford, Wexham Park Gardens, Slough, took the lead with excellent specimens, compact yet vigorous plants, bearing large richly coloured flowers. Mr. Mursell, gardener to Mrs. Burton, Town House, Streatham, was a good second, and Mr. Slater, North House, Sydenham, was third. For twelve *Calceolarias* the prizes were secured by Messrs. Ford, Guyett, and Long in that order. *Gloxinias* were fairly represented.

FINE-FOLIAGE PLANTS.—The exhibits in these classes were generally marked by a deficiency of colour, the *Crotons* and *Dracænas* especially. Perhaps the best class of all was that for *Caladiums*, in which Messrs. J. Laing & Son won the first prize with nine grand specimens capitally grown, and with the finely developed leaves delicately and beautifully coloured. Very remarkable were *Comtesse de Condeixa*, *Mithridates*, *Clio*, *L'Automne*, *Ferdinand de Lesseps*, *Leopold*, *Robert*, and *Triomphe de l'Exposition*. Mr. J. Day, gardener to W. E. Gover, Esq., Casino House, Herne Hill, was second with smaller but good specimens. For nine fine-foliage plants and the same number of Ferns Mr. Offer gained the first prize without any difficulty, his plants being large, and in the case of the Ferns, especially the *Cyatheas* and *Dicksonias*, uncommonly healthy and good. He was also first for nine *Crotons*, *angustifolius*, *Morti*, and *Weismanni* being the best for colour. Mr. Bird, Lodgemore Gardens, Dulwich, was the leading exhibitor with nine *Dracænas*, *Lindeni* being his finest plant as regards colour. Messrs. Offer, J. Hudd, Gordon House Gardens, Blackheath, and J. Lambert, Elfindale Lodge Gardens, Herne Hill, exhibited fairly well in this and other classes for *Dracenas* and *Crotons*. Mr. Ford had the best six fine-foliage plants, and was followed by Mr. Hudd.

Table plants contributed a good class, seven competitors staging eighteen plants each, and the majority of these were exactly adapted for table decoration, being of moderate size, light, graceful in habit, and bright. Mr. C. Lane, gardener to E. H. Coles, Esq., Burntwood, Upper Caterham, succeeded in winning the chief award with excellent plants in small pots. The best were *Crotons* Laingi, interruptus, *Dormanianus*, and *Lady Zetland*; *Cocos Weddelliana*, *Dracæna superba*, and *Cyperus alternifolius variegatus*. Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, was second with rather larger plants; and Mr. Simmonds, gardener to F. W. Wiltshire, Esq., Alverstone, South Norwood, was third with neat but somewhat small plants.

CUT FLOWERS.—The floral decoration department is invariably a feature at the Crystal Palace summer Shows, and on Saturday last there was an interesting and tasteful display. In both bouquet classes Messrs. Perkins & Son of Coventry were first with beautiful arrangements of choice flowers, Mr. G. Newman of Bromley following closely in each class with six examples. For six buttonholes Mr. Newman

succeeded in defeating Messrs. Perkins, gaining premier honours for charming sprays, &c., Orchids and Roses being chiefly employed. Messrs. Perkins and J. Peed & Son were second and third. Mr. H. Bawtree had the best three stands of flowers, and Mr. Prewett of Hammersmith the best twenty-four bunches of cut flowers.

Miscellaneous exhibits were numerous and of remarkably good quality. Messrs. Paul & Son, Waltham Cross, had, as already noted, a magnificent group of Roses in pots; Messrs. Sutton & Sons, Reading, contributed an exceptionally fine display of Calceolarias, representing their "Perfection" strain, and a group of the Cloth of Gold variety; Messrs. Laing & Sons, Forest Hill, had a group of choice tuberous Begonias, several of which were certificated; Messrs. Paul & Son, Cheshunt, showed a group of hardy flowers; Messrs. Barr & Son, Covent Garden, sent a collection of Daffodils and hardy flowers; Messrs. J. Peed & Sons, Roupell Park Nursery, had a tasteful exhibit of floral wreaths, crosses, sprays, buttonholes, &c., also a group of *Sarracenias*, *Anthuriums*, and *Cypripediums*; Mr. T. S. Ware showed a collection of Daffodils and spring flowers; Messrs. Ryder & Son, Sale, sent examples of their Japanese Primulas, varieties of *P. cortusoides*; Messrs. Balchin & Son, Brighton, showed plants of the brilliant blue *Leschenaultia biloba* major, and Messrs. J. Carter & Co. exhibited plants of Wallflowers, Miss Primrose Carter, pale yellow, and Golden Bedding, deep orange. Certificates were awarded for the following *Primula cortusoides*:—Queen of the Whites, Ruby Queen, Harry Lee, Alba magnifica, Leo H. Grindon, and Mrs. Ryder, from Messrs. Ryder and Son, which have been previously noted, also for those here described.

Begonia Beauty (J. Laing & Sons).—Double crimson, with a creamy centre; very full and distinct.

Begonia Mammoth (J. Laing & Sons).—An enormous double scarlet flower; very massive, and aptly named.

Begonia Rosy Mari (J. Laing & Sons).—A rich clear rose, finely formed flower.

Begonia alba plena compacta (J. Laing & Sons).—Flower double, very large, of good form, and pure white; compact and dwarf in habit, but very floriferous.

Genista Andreanus (Paul & Son).—A novel and peculiarly handsome hardy shrub of slender graceful habit, with small leaves, and large bright yellow flowers, having the "wings" a rich reddish brown, contrasting well with the other portion of the flower.

Rose Corrinna (W. Paul & Son).—A Tea Rose, with substantial flowers of a bronzy or rosy salmon hue, very distinct, and tint that is likely to please many.

Anthurium Schertzerianum sanguineum (J. Peed & Son).—A fine variety, with large broad well-shaped spathes of a rich colour.

ROYAL BOTANIC SOCIETY.

MAY 14TH.

WHEN a Society has once secured a reputation for liberal encouragement of exhibitors it can ensure shows of a highly satisfactory character, comprising the best examples of cultural skill to be obtained either in plants, fruits, or vegetables, and therefore possessing some educational value. When, too, a Society confines itself entirely to the show element in horticulture it is more than ever necessary to render the exhibition as complete as possible. It is therefore a most dangerous policy to start considerably reducing prizes without making some corresponding alterations in the classes. This course has been adopted by the Council of the Royal Botanic Society in recent years, and the result is that the character of the once famous shows is rapidly changing. Exhibitors complain that the second and third prizes offered in the large specimen classes will not pay the expenses of carriage, and the consequence is the chief awards are left to a few who practically make exhibiting a trade. Certain specimens are grown to be conveyed to as many shows as possible, and the grower is expected to be able to show a favourable balance at the end of the year. Were this confined to nurserymen it would be perfectly legitimate, but when amateurs take up such a method of procedure it is at least somewhat degrading to genuine horticultural enthusiasm.

The schedules of the Royal Botanic Society require a thorough revision and considerable alteration to render them in accordance with the times, and many would gladly welcome some indication of energetic action in popularising the work of the Society.

The summer shows held in the spacious marquee are, of course, invariably attractive; the contour of the ground and the style of the place altogether are unsurpassed in producing tasteful floral effects. The courteous Superintendent, Mr. Coomber, knows well how to take advantage of the capabilities of the situation, and he has earned a well merited reputation for skilful arrangement. At the Show held yesterday (Wednesday), the usual style was adopted with excellent results. Flowers and foliage, bright and soft colours, were contrasted or associated with most satisfactory results, but still that essential element in a first-rate horticultural show, keen and abundant competition, was wanting, and this detracted from the interest of an otherwise fine display. Miscellaneous non-competing exhibits were, as they always are, very numerous. These help greatly in a popular show; something more is needed in one based upon competitive classes.

Orchids have been strongly represented at some of the shows, but on this occasion they were few, only two collections in competition were entered. Mr. T. Whellans, gardener to the Duke of Marlborough, was first with twelve Orchids, remarkably fine specimens of *Cypripedium*

selligerum majus, eight flowers, *Cattleya Mendeli*, fifteen flowers, *Laelia purpurata*, nine racemes, *Odontoglossum sceptrum*, five strong racemes of large flowers, *Cypripedium Lawrenceanum*, thirty-two flowers, *Cattleya Lawrenceana*, well flowered, *Dendrobium thyrsiflorum*, a very large specimen, *Odontoglossum vexillarium*, *Cypripedium caudatum*, with about forty flowers, *Cattleya Mendeli*, *Dendrobium Jamesianum*, and *D. suavisissimum*. Henry Little, Esq., Baronshall, Twickenham, gained similar honours for a group of Orchids tastefully arranged with Ferns on a bank.

Pelargoniums furnished much bright colour, and the groups and corner banks had a capital effect. Mr. C. Turner, Slough, and Mr. D. Phillips, Langley Broom, Slough, were the prizetakers as usual in open and amateur classes, their plants being in excellent condition and well flowered. Hardy herbaceous plants and alpine were shown by Messrs. Paul & Son, Cheshunt, and the first prize was secured in each class with admirably representative collections.

Roses were good, especially the premier nine from Messrs. Paul and Son, large healthy plants, good alike in foliage and flowers. Beauty of Waltham and Catherine Soupert were notable for their fine condition. Exhibitors in other classes were Mr. W. Rumsey, Mr. J. F. Mould, and Mr. C. Turner, who had smaller but good plants. Mr. Rumsey, Waltham, was first in the class for twenty Roses, similar to those shown at the Crystal Palace on Saturday.

Azaleas were bright and effective, particularly the premier six from Mr. C. Turner, large conical specimens bearing abundant flowers. The second prize plants in the same class from Mr. James were not fully out, and one plant was very thin. In the amateur class for six Azaleas Mr. Offer had some well grown plants bearing numerous flowers. Model, Due de Nassau, and Roi d'Hollande were unusually fine.

Stove and greenhouse plants were deficient in several classes, and some were much inferior to those usually seen in large classes. Mr. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley, had the best ten specimens, and these constituted a fine group on one of the slopes, *Ericas*, *Ixoras*, *Statice*, *Tremandras*, *Dracophyllums*, and *Anthuriums* having a capital effect. The same exhibitor was also first with six stove and greenhouse plants of similar size. Mr. J. F. Mould was also first for six specimens in the nurserymen's class, fairly good plants and well flowered. He was also second with twelve plants.

Mr. Offer, Handcross Park Gardens, Crawley, was first with six large Ferns, healthy finely developed specimens; with nine *Dracenas*, moderate sized plants, furnished with leaves to the base; with six Azaleas, small globular plants, crowded with flowers, being followed by Mr. T. Lockie, Oakley Court Gardens, Windsor, and Mr. James, the latter showing very poor plants. Mr. Offer also had the best six fine-foliaged plants, comprising gigantic *Cycas revoluta*, *C. circinalis*, *Encephalartos villosus*, *Croton Warreni*, *Croton undulatus*, and *Dasyllirion acrotichum*. Mr. H. James, Castle Nursery, had the best six Heaths, small but healthy plants. He was also first for twelve stove and greenhouse plants, and second with six, but they were not of special merit.

MISCELLANEOUS EXHIBITS.—As already indicated these were very numerous and of capital quality, varied and beautiful groups occupying considerable space in the marquee. Three of the central stages were devoted to contributions of this character, and these were unsurpassed in the whole show for interest and effect. Messrs. B. S. Williams and Son, Upper Holloway, had a grand group of Orchids and fine-foliage plants (silver-gilt medal). Messrs. J. Laing & Sons, Forest Hill, had a charming group of *Caladiums*, tuberous *Begonias*, Azaleas, Orchids and Ferns (silver-gilt medal). Messrs. Wm. Paul & Son, Waltham Cross, had a superb group of Roses in pots and a large collection of cut Roses (large silver medal). Mr. T. S. Ware, Tottenham, had a large collection of hardy plants (small silver medal). Messrs. Paul & Son, a group of *Lilacs*, shrubs, *Rhododendrons* and Azaleas (bronze medal). Messrs. Ryder & Son, Sale, a collection of Pansies and Japanese Primulas. Mr. G. James, Slough, had a group of *Calceolarias* (large bronze medal).

Messrs. J. Veitch & Sons, Chelsea, showed a large choice group of plants similar to those at the Drill Hall on the previous day; Mr. C. Turner, Slough, had a group of fine *Lilium Harrisii*; Mr. J. Walker of Thame two boxes of *Maréchal Niel* Rose blooms; Messrs. Kelway and Son, Langport, had a large group of Paeonies and hardy flowers; Messrs. Barr & Son showed Daffodils and hardy Ferns; Mr. J. Forbes, Hawick, a collection of Pansies; and Messrs. Balchin & Son, Hassocks Gate, a group of *Leschenaultia biloba* major.

Certificates were awarded for numerous plants, some of which have been previously honoured elsewhere, and one at least had been certificated by the Judges at the summer Show of the Royal Botanic Society last year under another name. Some of the plants distinguished were as follows:—*Cypripediums Elliottianum* (Low & Co.), *Acer Prince Hendjery* (Paul & Son), *Cattleya Mendeli alba* (Mr. White), *Genista Andreanus*, *Acer japonicum laciniatum*, and *Nephrolepis cordata laciniata* (J. Veitch & Sons), *Calla Elliottiana* (Knight), *Abies excelsa mutabilis*, *Juniperus japonica aurea* (J. Veitch and Sons), *Syringa grandiflora alba* (Kelway), *Trollius caucasicus aurantiacus* (T. S. Ware), *Tulipa elegans alba* (Barr).

SCOTTISH AURICULA AND PRIMULA SOCIETY.

THE fourth Exhibition of the Scottish Auricula and Primula Society was held in the City Assembly Rooms, Dundee, on May 8th. There was a large and good collection, and the attendance of the admirers of this special flower was excellent, the various points being criticised keenly.

The Show was formally opened by Robert Cathcart, Esq., of Pitcairrie, in a neat speech, in which he expressed the hope that the taste for the Auricula would spread. My colleague, Mr. J. Morris of Dundee, and myself when judging the plants came to the conclusion that the quality was an improvement on last year, the closest attention to the various points being necessary repeatedly to decide the awards.

In addition to the prizewinners which are named below, Mr. J. Morris exhibited a collection of twelve exceedingly well grown Auriculas, having fine blooms, including selfs—Morris's Fidelity, King Lea, and Blue Gown, Duke of Argyll, Barlow's Mrs. A. Potts (a grand bloom of the finest self in commerce). The Secretary, Mr. W. Stratton, Dundee, to whom most of the success of this Show is due, had a good display of plants, which, with Calceolarias from Miss Cox, some interesting Orchids from Mr. Mudie, and miscellaneous plants from the local nurserymen, added much beauty and variety to the Show, which had a most pleasing effect. The Scottish Society have the use of a room for this Show, which is far superior to those used by the southern societies.—F. POHLMANN.

PRIZE LIST.

Class A, six dissimilar Auriculas.—Mr. W. Kilgour, Blair Drummond, first with Mrs. Potts, Beeston's Apollo, George Lightbody, Lancashire Hero, Acme, and Kilgour's Andrew Millar; Mr. J. D. Kerr, Douglasfield, second with Acme, George Lightbody, Black Bess, F. D. Horner, Col. Taylor, and George Rudd; Mr. James Black, East Calder, third with George Lightbody, Brunette, John Simonite, F. D. Horner, Mrs. Potts, and Mrs. Dodwell.

Class B, four dissimilar Auriculas.—First, Mr. W. Kilgour, with Talisman, Acme, Blackbird, and Geo. Rudd; second, Mr. J. D. Kerr, with Acme, Blackbird, Geo. Lightbody, and Col. Taylor; Mr. W. Stratton, Dundee, third with Lancashire Hero, Acme, Blackbird, and plant unnamed, possibly Alex. Meiklejohn.

Class C, two dissimilar Auriculas.—Mr. W. Kilgour first with Geo. Lightbody and F. D. Horner; Mr. J. Kerr second with Acme and Geo. Lightbody; Mr. J. Menzies, Duns, third with Acme and Mrs. Erskine.

Single specimens.—Class D, one green edge.—First Mr. J. Menzies, Duns, with Prince of Greens (this was also premier of its class and premier of the Show); second, Mr. W. Kilgour, with Rev. F. D. Horner, and third with Lancashire Hero. Class E, one grey edge.—First, Mr. J. D. Kerr, with Alex. Meiklejohn, second with Geo. Rudd, third with Geo. Lightbody. Class F, one white edge.—First, Mr. W. Kilgour, with John Simonite, second with Regular, third with John Simonite. Class G, one self.—First, Mr. W. Galloway, with Patronella; second, Mr. J. Menzies, with Black Bess; third, Mr. W. Kilgour, with Heroine.

Premier green, Prince of Greens, from Mr. J. Menzies; premier grey, Geo. Lightfoot, from Mr. W. Kilgour; premier white, Acme, from Mr. W. Kilgour; premier self, Mrs. A. Potts, from Mr. W. Kilgour. Seedling selfs, special prize.—First, Mr. W. Kilgour, for Vidette (certificated), and Cornet (certificated).

Alpine Auriculas, six dissimilar.—First, Mr. W. Kilgour; second, Mr. J. Menzies. Four dissimilar.—First, Mr. W. Storrie; second, Mr. J. Black. Six gold-laced Polyanthus.—Mr. J. Menzies. Six dissimilar, Fancy.—First, Mr. W. Stratton; second, Mr. O. Stratton.

FRUIT FORCING.

PINES.—Attention to details is very essential in fruit, particularly in Pine Apple culture, at this time of the year, when the weather is changeable, especially as regards plants with the fruits in an advanced state, a moderately moist atmosphere and high temperature being necessary to their well-being, which condition renders them more susceptible of injury, the effects of sudden outbursts of sun telling disastrously, especially upon the crown, which is not infrequently scorched if the ventilation is not carefully attended to. Large well-finished fruits are only to be obtained by attention to details, especially when the plants are cultivated in pots. Watering will require attending to once a week, but avoid indiscriminate periodical waterings. Plants that have heat at the roots by means of hot-water pipes need more water than those having the heat furnished by means of fermenting materials. The former should have water as often as required, on every occasion employing some stimulant; 1 lb. guano to 20 gallons of water is a suitable quantity. Amit air at the top of the house, maintaining the temperature during the day at 80° to 90°, closing at 85°, but unless it be desirable to enlarge the crowns do not quite close the houses. Fire heat must be employed to prevent the temperature falling below 70° at night, and to raise it to 75° in the day, the bottom heat being kept at 80° to 90°. Syringe the house and plants two or three times a week according to the weather, and maintain the atmosphere in such a condition as to secure the perfect development of the fruit.

PEACHES AND NECTARINES.—*Trees Started at the New Year.*—The fruit is in the last stages of stoning, and must not be subjected to a higher temperature by artificial means than 60° to 65°, commencing

to ventilate early and at 65°, not allowing 75° to be exceeded without full ventilation. Tie in the shoots as they advance, removing superfluous growths, as it is important no more be trained in than can have full exposure to light and air. If the shoots are crowded thin them well as soon as the stoning is completed. Allow one fruit to every square foot of trellis covered with foliage, which will be one to every shoot of last year, although vigorous shoots may be allowed to carry two fruits. By apportioning the fruit to the vigour of the trees or degrees of vigour in different parts the evenness of vigour may be maintained throughout the tree. After stoning, maintain adequate moisture in the house, watering the inside border copiously, which in well drained borders will be required at least once a week, mulching the surface with about 2 inches thickness of short half-decayed manure. Unless it is desired to accelerate the ripening, continue 60° to 65° as the night temperature, and 65° by day artificially in dull weather, and 75° with sun heat, closing at the latter with plenty of moisture. In a high temperature and moist atmosphere Peaches swell to a great size after stoning, but are not so tempting in appearance nor so well flavoured as those in less heat and moisture with freer ventilation.

Trees Started in February.—The fruit of these will soon be commencing stoning and should have the number reduced, leaving two fruits on strong shoots, but one will be sufficient on the weaker. The fruit in all instances must be the best situated for receiving air and light. Thin the shoots where crowded. The temperature by artificial means may be kept at 55° to 60° at night, and 60° to 65° by day artificially, ventilating from 65°, and fully between 70° and 75°.

Trees Started in March.—The fruits are swelling and require to be freely thinned. It can now be seen which have taken the lead. Two or three will be ample to leave on strong shoots, and less on weak shoots. Afford liquid manure to weakly trees, but vigorous trees being more prone to cast the fruit must have clear water only. Remove all superfluous shoots, the remaining growths being trained to the trellis as they advance.

Late Houses.—The fruits are well set, and syringing will be needed in the morning and early afternoon, but on fine days only, to rid the fruits of the remains of the blossom. Commence thinning when the fruits are the size of horse beans, removing the smallest and worst placed, leaving very few more than will be required for the crop. Disbudding and heeling in the shoots must be carefully attended to. A temperature of 50° at night will be safe, and 55° by day artificially, ventilating freely above that unless it is desired to hasten the crop, when a temperature of 55° at night and 60° to 65° by day artificially may be secured, with 70° to 75° by day, ventilating from 65°.

Unheated Houses.—The promise of an abundant crop seems assured, the set being good, nine-tenths too many for a crop. A moderate syringing on fine mornings will be a great assistance in ridding the fruit of the remains of the blossoms; but there must not be any attempt at an afternoon syringing for the present, and no sprinkling practised likely to cause a moist temperature at night, as the weather is not yet to be depended on, and a sudden severe frost occurring whilst the house is moist is very much more likely to prove disastrous to the crop than if the atmosphere is dry. Ventilate at 50°, not allowing an advance above 65° without full ventilation, and close at 50°, or before if there is a prospect of frost at night. If water be necessary apply it sufficiently early in the day to allow of the surface becoming fairly dry before closing time.

CHERRY HOUSE.—Cherries are ripening rapidly; the fruits must be kept dry, but the surface of the borders should be rendered moist by damping with the syringe, air being admitted constantly, or condensation will seriously affect the fruit. Damping the border is calculated to mislead as regards its condition, therefore if necessary a thorough supply of water must be afforded without delay. Tie-in the shoots as they lengthen, and stop those not required for training in, at the fifth leaf. Black aphides may be kept in check by fumigation or by dipping the shoots or leaves in tobacco water. Ventilate freely on all favourable occasions, and when the external conditions are unfavourable recourse must be had to the heating apparatus to ensure a circulation of warm dry air. Netting will be necessary over the ventilators with sufficiently small mesh to exclude birds, which have a striking partiality for Cherries.

CUCUMBERS.—Clean growth is imperative in the cultivation of fruits. Aphides must be kept under by fumigation, filling the house with smoke in the evening, and repeating in the early morning, or it may be practised on two or three consecutive evenings. It is essential to have the foliage dry, but the floor well damped. Red spider is the worst enemy, and is sure to put in appearance. Remove the worst leaves, and keep the atmosphere charged with ammonia vapour by damping the floor in the evening with guano water, supplying the roots with the same about twice a week. The hot-water pipes may be thinly brushed over with sulphur mixed with skim milk to make it adhere. Let the roots be duly supplied with water, affording the same temperature as the house or bed. Plants in bearing all the winter will now be showing signs of exhaustion, and had better be removed, and young plants placed in without delay. All the old soil must be removed and the house thoroughly cleansed, using entirely fresh sweet material for the young plants. Assist young plants showing signs of weakness by removing the staminate flowers and the first fruits, stopping at every third or fourth joint, removing all weakly and superfluous growths. Shading will be necessary for an hour or two in the middle of the day when the sun is hot, especially houses facing south, but let it be done before the plants flag, as afterwards it will only prevent further injury, flagging being invariably injurious. Houses with roof lights facing east

and west will not require shading. Little or no fire heat will be required by day, shutting the valves at about 8 A.M., and opening them again at about 5 P.M. Syringe the plants moderately between 3 and 4 P.M., keeping a good moisture all day by damping the floors.

Pits and Frames.—Sow seed for raising plants to occupy pits and frames, a fair bottom heat being first secured by using the less decomposed material from Seakale, Vine borders, or exhausted hotbeds, which, with about a fourth of fresh material, will afford all the heat required. Close pits and frames as early in the afternoon as is safe, not allowing the temperature to exceed 90° to 95°, and employ good night coverings. Maintain a good bottom heat by duly renewing the linings. Prepare for planting out ridge Cucumbers under handlights, the plants being hardened off previously.

STRAWBERRIES IN POTS.—Noble is one of the finest Strawberries for growing in pots. It may not colour well to the "tip" when subjected to early forcing, but forced to ripen in late March or early April it is of fine size and colours well. Auguste Nicaise is unquestionably the best of second early forcing Strawberries, the fruit being large and bright in colour. We still give preference to La Grosse Suerée as a first early, following with Noble and Auguste Nicaise. These two last may be had with a dozen to the pound or dish ordinarily, and are very attractive in appearance. La Grosse Suerée does not usually require above twenty fruits to the pound dish, and it is very bright and clear in colour. Those three have a happy knack of not flowering their vigour away in a number of useless blossoms, but give six to eight or a dozen fruits in a very full crop per plant, but number always tells against size of individual fruits, and mars the quality to a very serious extent. To follow those we have President and Sir Joseph Paxton, which are large, getting up in "king" fruit to 1½ oz., Sir Joseph Paxton being a heavier and firmer, as well as better forcer, and sometimes reaches 2 ozs. Sir Charles Napier is a fine bright fruit, and crops splendidly, it, with Dr. Hogg, being the finest for late work. The latter is superb in flavour. It is necessary to grow Vicomtesse Hericart de Thury as an early, both forced and outdoors, in order to secure succession of quality. We also find Unser Fritz a fine late sort, affording 2 oz. fruits of a brilliant glossy red. For quality there is none to equal Dr. Hogg or British Queen. Some like a glossy dark fruit like Sir Harry and Waterloo, but they are soft, which, however, does not matter when they are grown for home consumption.

There must not be any lack of moisture at the roots of Strawberries as when the sun is powerful the fruits are apt to have the skins dried, and they do not swell freely afterwards. After the fruits commence swelling a brisk moist atmosphere is essential, supplying liquid manure liberally until the fruits change colour, when it must be discontinued, giving less water at the roots. Admit air freely whenever the weather is favourable, avoiding drying currents. Nothing is so advantageous as well thinning the fruits, especially the large varieties. See that late plants are free from aphides, and fumigate if there be the least trace of them. Do not keep fruiting plants a day longer in the houses than absolutely necessary, as it is hardly possible to force Strawberries without their being infested with red spider. Water the plants twice a day, and in bright weather three times, at least examine the plants for that purpose, and supply it if required. Liquid manure may be given at the afternoon watering.

THE FLOWER GARDEN.

Alternantheras, Coleus, and Iresine.—Now is a good time to put in a large batch of cuttings of these. They strike root in a few days, and by the time wanted for the beds, or say towards the middle of June, fine strong plants will be ready. The simplest method of preparing large or moderately large numbers of each or all of these useful plants is to either utilise a partially exhausted hotbed, or to form a shallow new one, in either frame or pit, sufficient material being thrown inside to raise the soil well up to the glass. A layer of about 4 inches of light fine sandy soil is sufficient, the cuttings being dibbled out 3 inches apart each way direct into this. Every short piece will strike, and no time need be wasted in trimming them. The lights, if the beds are not dangerously hot, to be kept on closely, and shade must be afforded whenever the sun shines on them. Later on, or when the cuttings are well rooted, a little air must be given during the hottest part of the day, the plants being eventually well hardened and finally transferred direct to the beds.

Late Struck Verbenas.—The latest rooted plants not unfrequently grow more strongly than do those that have been longer exposed to various injurious agencies. They succeed well treated much as advised in the case of Alternantheras, the soft young tops striking root in a week. Being stopped soon after they commence to grow afresh, the plants break strongly and move well.

Annuals that may yet be Sown.—French and African Marigolds and Tagetes germinate very quickly under glass, and may be sown thinly either in boxes or on beds of fine soil in frames, and from which they may be transplanted direct to the beds and borders. The miniature forms of French Marigold and Tagetes signata pumila are fairly good substitutes for Calecolarias, and should be raised in quantity if the latter are scarce or are liable to fail. Amaranthus, of which there are several with ornamental foliage, grow very rapidly, late raised plants being less liable to receive a severe check either before or after planting. Sow in pans in heat, prick out the seedlings singly into small pots, and keep growing in heat till large enough to harden off and plant out. They are somewhat tender, and ought not to be put out much before the middle of June. Ricinuses again are of rapid growth. Sow seed singly in 3-inch pots, and keep the pots in heat near the glass till the end of May, then harden off and plant out during the second week in

June. Sunflowers may, as a rule, be sown where they are to grow, but early strong plants may be had by sowing seed in gentle heat, potting off the seedlings singly, and planting out when large and hardy enough. Balsams may be similarly treated.

Hardening off Plants.—The time has now arrived for transferring the Zonal Pelargoniums well established in pots and boxes to a sheltered position where they can be temporarily protected if need be from late frosts. What bedding plants, more especially those in boxes, suffer from most is too much moisture, heavy cold rains doing much harm. They ought not, therefore, to be watered in a reckless manner, and never in the evening. When the pits and frames are cleared of the more hardy plants, they will be available for the forwardest seedling and cutting raised plants of various kinds, but the tender Coleus and Iresine should not be too quickly transferred from warm quarters to much colder positions or they may experience a check from which they will not properly recover. They are best kept in gentle heat till near the end of May.

THE BEE-KEEPER.

SEASONABLE NOTES.

THE fine weather experienced at the beginning of the month changed on the 4th with thunder showers, and it has been much cooler. The sky keeps cloudy, preventing the rapid evaporation of the moisture, so beneficial to the growth of all crops, although retarding the preparation of land for Turnips and other late crops. For the present bees are being deprived of the benefit of the blossom of the Sycamores so plentiful this year. But we do not count it all loss. Rather I would see this than a superabundant gathering of honey, which sometimes hinders the breeding to the loss of the bee-keeper, the hives being not in the best condition for gathering from the Clover as when they are kept steadily breeding till the proper time, the older bees being preserved, and the younger ones more numerous, and hives, as a rule, better conditioned in every respect for the gathering than when they are favoured with fine weather and an abundance of Sycamore honey during May.

SWARMING.

This has commenced, but the dull weather is retarding others. We prefer June to May swarms, but in some districts which are earlier May swarms are most desirable. Swarms not later than the 15th of June is the best time for the young queens to mate. The two last weeks of June and the two first of July are commonly the warmest, and appear the most natural time for the fertilisation of queens. It not unfrequently happens that queens hatched in May are not fertilised till June, although drones may be numerous. The bee-keeper will study his own interest best to keep no queens for profit but those fertilised in June or July, raised from strong stocks and by young bees.

REMOVING FILLED DIVISIONS BEFORE APPLYING SUPERS.

"Is it advisable to take off the top body box previous to putting on the box containing the supers on the Lanarkshire storifying hive? I am under the impression that by taking off the top box when filled with honey the bees would have less distance to travel before reaching the supers, returning the box after the harvest is over for the bees to winter on.—R. A. C."

The above query covers a wide and important field in bee-keeping. The system has been practised here for a long time, both by removing the upper and under division, as circumstances demanded, the main object being to crowd the bees into the supers, and prevent or delay swarming; it cannot be prevented at all times nor in every case, but we use the means.

There are times and seasons when it is inadvisable, but in others very advisable to so manipulate. In 1872 our bees missed the Gooseberries, and the spring throughout was untoward, consequently they were in a backward state. The Sycamores had abundance of bloom, and the weather was favourable, the bees soon filled every available space with honey, completely stopping breeding. Removal of the upper divisions of the storifying hives and the side combs of the one-divisioned frame hives would have been done, but the weather changed to cold and wet, which delayed the operation, and well it was so, for the season turned out a failure, but had the weather kept fine the surplus honey would have been removed and the bees encouraged to breed to be in strength for the Clover.

At one time "raises" were extensively used for maintaining strong stocks, affording a drying ventilation that the ventilating floor has superseded them. Just before the honey flow they were placed under the non-swarming hives for a day or two, sometimes longer, depending altogether on the weather. The extra room

tended to delay swarming, and when removed at the commencement of the honey flow immediately crowded the bees into the supers. The combs built in the "raise" were employed for guides or "tooks," as they were termed, for the honey boxes, the splitting of the top bar to receive the combs, and the heated iron along with wax to fasten them, were plans or contrivances invented to complete the system, and the way we produced ornamental designs before foundation was heard of. Height is no obstacle for bees to reach supers; it is in accordance with the nature of the bee to ascend, and in opposition to the clumsy method of lateral extension.

Surplus honey serves no good purpose in a hive during summer, and if it is sealed, remove it, but in doing so care must be exercised to prevent brood drawing. A little food will serve the purpose. Honey is of more value than sugar; the latter may be profitably employed, instead of returning the division of honey. In all cases where it is inadvisable to remove the upper division, the side combs, if sealed, should either be removed and frames of foundation substituted, or the seals broken, so as to induce the bees to enter the supers, which they do reluctantly if they have to pass over sealed combs.

When bees are located in a full sized hive, all the small quantities and different varieties of honey, sometimes (the reverse of fine), is stored above, leaving ample breeding space below. Such divisions will be best returned to the hive, and the bees will neither be disheartened nor lessened in numbers by the act, and supers will be filled expeditiously, providing the foregoing precautions are taken, as well as to preserve the normal form of the crown of the hive. The foregoing will perhaps impress bee-keepers with the importance of the three-divisioned-bodied Lanarkshire hive, and to answer several other queries which a modern writer has prompted by advising bee-keepers "not on any account to purchase a hive that has not the Association standard size frames, as another size will only be worth the price of so much firewood!" But apparently the author is not very clear upon the question, for after descanting upon the inadvisability of using deep frames for storifying and setting forth the advantages of shallow frames, he says:—"We can see many advantages in thus using shallow frames for extracting purposes. No wire need be used, the combs are always clean, the difficulty of uncapping is reduced to a minimum, they very rarely break out of the frame when extracting, and the honey is of as fine a colour as that extracted from sections. To Mr. Carr of Cheshire we are indebted for the promulgation of this system."

Not so fast Mr. Webster, the system was promulgated a long time before Mr. Carr's day, but you are very near correct in what goes before the last sentence, only it is a pity your experience did not extend further to have enabled you to state the properties the shallow frames possess for bee-keeping generally. Perhaps the next edition of your useful work will do so, as well as to remove other errors, and tell us a hive not having standard frames need not "be burned." The book has been sent me with a number of queries, but no name attached, so I suppose they are readers of this Journal, which I may answer again, and supplement the answers to "R. A. C." as the season advances.

COVERING HIVES.

"Will 'A Lanarkshire Bee-keeper' give his advice as to covering hives, as many more are interested than myself? I use the hives without any external covering further than filling the top box with hay, then covering with a sheet of iron weighted with bricks. I shade with mats during the summer. I would like to hear of the advantages, as I thought sacking would hold water instead of allowing it to escape. But if covering is better I must adopt it. I must own that the paint blisters and peels off uncovered hives.—R. C."

It is a good plan before tearing down a structure either to have a makeshift or a new permanent building ready for the reception of the inmates whatever they may be. Our modern reformers in bee-keeping did not adhere to this policy, being ignorant both of the habits and nature of bees, as well as of the methods of managing them and their domiciles. They set to work demolishing all the appurtenances connected with bee-keeping, and some of them went so far as to express their dissatisfaction with the build and form of the bees themselves, and made an effort to alter the structure, but the bee still reigns supreme, and happily the bee-keepers north of the Tweed maintained their position. Double cased hives are expensive, clumsy failures; single cased hives are light and handy, suitable for every phase of bee-keeping and every clime, but they must be protected. Both single and double cased hives unprotected or unventilated during winter condense the moisture upon the inner walls, rotting the combs, destroying the honey, and causing death and disease to the bees. The damp oozes through the wood and lifts the paint and rots the hive. Double cased hives always do this, but well protected single cased ones will carry

the perspiration of the bees through the top of the hive and its entrance, as well as what falls upon the sides will pass through the walls, hence the reason I advocate thin walled hives. Well protected single walled hives during summer prevent the heat of the sun melting the combs as well as preventing the bees crowding out and loitering instead of working. During the spring the hive is kept at a uniform degree of temperature, thus breeding is carried on uninterruptedly and in a regular manner without the slightest chance of brood drawing or brood chilling taking place.

Even with all our care during extremely warm weather bees are apt to get too hot. I shade as well as cover my hives with damped grass or cloths. About twenty years ago I introduced a shade for bee hives—a light simple contrivance, as a framework crossed the top of the hive, and a sheet of calico thrown over it held in its place by pockets with stones. This simple device, like most others, was appropriated. Mr. Abbott might have seen it at Glasgow; though shortly after he wrote that "No one had attempted a shade for hives."

I almost forgot the most important part. Well covered hives of bees will build more comb during the night than naked ones, consequently more honey is gathered next day, and the comb is always whiter. I trust these few hints will enable bee-keepers to see the advantages gained, and place themselves in a position independent of the advice of any association, and enjoy the "privilege of independence" at least with bees.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Thomas S. Ware, Hale Farm Nurseries, Tottenham, London.—*Catalogue of Dahlias and other Plants.*

James Carter & Co., 237, High Holborn, London.—*Catalogue of Seeds and Plants.*

James Veitch & Sons, 544, King's Road, Chelsea.—*Catalogue of New Plants for 1890 (illustrated).*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Summer-pinching Fruit Trees (F. J.).—Thin the shoots to prevent overcrowding, and allow the growths to extend till July, then pinch them as required. If the trees require much summer pruning to keep them within bounds it is certain they will not be profitable, and should have their vigour arrested for the formation of fruit buds. This can only be effected by judicious root-pruning or lifting, and affording firmer soil. Remove the ill-placed shoots at once. The wood is firm or soft, fruitful or unfruitful, as it is exposed to the sun and air.

Chalk for New Garden (Imprimatur).—From your description of the soil a dressing of chalk would probably do good; but unless it is in very small particles it might be better to trench the land first and have the chalk placed on it in small heaps before winter, so that it would be disintegrated by the action of wet and frost for spreading and forking into the ground in spring. From 60 to 80 cubic yards per acre are applied to heavy chalkless soils. The best chalk for your purpose is usually taken from a good depth in pits, not from near the surface.

Mildew on Roses (F. J.).—Syringing with a solution of soft soap 2 ozs. to the gallon, and a handful of sulphur added to three gallons, is an effectual remedy, applied so as to reach every part of the plant, and is good against other or insect pests. We presume it is the white mildew to which you allude. It may also be destroyed by Harris's sulphide of potassium. Indeed sulphur is the most reliable frustrator of its ravages. Sulphur water may be prepared as follows:—Boil 1½ lb. flowers of sulphur and 1½ lb. quicklime in a gallon of water, preferably in an earthen pot, for a quarter of an hour, stirring constantly whilst boiling. Allow it to settle, and when cool pour off the clear liquid and place in a stone bottle, keeping closely corked for use. Use a quarter of a pint of the preparation to a three-gallon can of water, applying it with a syringe.

Vine Leaves Diseased (G. B.).—The leaves are attacked by a fungus, which at first appears as spots or roundish pustules, which soon extend, and becomes confluent adjacent to the midribs, isolated or less confluent on the thinner tissue. The spots are at first greenish yellow, soon passing to pinkish grey, and finally become black or dark brown, with a reddish brown border or next the unassailed portion of the leaf. The fungus is not very destructive except under special conditions, such as a close vitiated atmosphere, alternating with checks consequent on injudicious ventilation, and is most prevalent in structures where the roots of the Vines are in rich, wet, cold, outside borders. There is no preventive equal to a genial freely ventilated atmosphere, so as to insure sturdy growth, thoroughly stout firm-textured foliage, therefore better able to resist the intrusion of the fungoid germs through the epidermis. The growth when attacked is arrested or, in bad cases, destroyed; but this rarely occurs when the foliage becomes sufficiently hardened, although one form of the parasite not infrequently attacks lateral growth in autumn, completely crippling the foliage and preventing its enlargement. There is no remedy. Perhaps a solution of sulphate of iron would prove beneficial, a quarter of an ounce to a gallon of water being sufficiently powerful, distributed over the border at the rate of one gallon per square yard. Burn the prunings summer as well as winter.

Peach Leaves Injured (G. H.).—The leaves have been scorched by fumigation, and the parts affected with blisters will fall, giving the foliage a scalloped appearance as if gnawed and eaten by insects. The leaves, in some cases, fall entirely, but not usually, as the parts near the midribs are generally firmer in texture, and not so liable to be covered with moisture as the softer parts. It is always a risky proceeding fumigating Peach houses in the early stages of the trees' growth, as the leaves are not only liable to suffer, but the fruit is in danger of being damaged, therefore it should always be practised very carefully, and with considerable judgment. It is necessary to have the foliage dry, and deliver the smoke as cool as possible. The more healthy and succulent the foliage is, the more susceptible to injury are the leaves and incipient fruits, therefore we make a practice of fumigating on two or three consecutive evenings moderately, to avoid as far as practicable making a mistake. Whether the trees have suffered through want of water or not, that is not the cause of the foliage being in its present condition. Eighty gallons is not much to give to nine trees in two months, but as they are not large trees, it may, or may not, have been adequate to their requirements. The trees must be kept well supplied with moisture at the roots, never allowing the soil to become so dry as to affect the foliage. When the soil is becoming dry it must be watered so as to moisten it as deeply and as far as the roots extend. Two 3-gallon watering pots full of water, allowing for loss, are equal to about an inch of rainfall per square yard, which is a minimum quantity to apply to fruit borders at one time to insure their being moistened down to the drainage.

Peaches and Nectarines Falling (M.).—The cause is imperfectly assimilated matter, usually termed imperfect wood. Food in the previous year has not been stored in the adjacent wood to sustain the fruit in the early stages of its development, and the trees make an effort to rectify the deficiency by the production of growth, in order to a large elaborative power and resultant assimilation of the food supplies. This is often frustrated by the cultivator by too early and too free and full disbudding, and the maintenance of a close moist atmosphere, which is favourable to growth rather than elaboration and assimilation; the fruit falling in the incipient state from a deficiency of stored food. The wood is very unripe, weak, and long jointed. Therefore recourse must be had to root-pruning, or preferably to lifting, if it can be safely done. The roots should be raised and laid in firmer soil, so as to insure stouter, shorter jointed, thoroughly solidified wood. The soil not being calcareous may have a sixth of old mortar rubbish added to it, or if it be light add a similar proportion of clay marl, and make the soil as firm as possible about the roots. This should be done after the wood becomes firm and before the leaves fall, the close of September or early in October being a suitable time in your case. With care we see no reason why the trees should not be successfully operated upon in the manner indicated, which is the only means calculated to effect a beneficial change. Keeping the house close and moist for the bedding plants would aggravate the evil, as with a drier atmosphere and allowing the disbudding to stand over longer than usual, the sap would have been better elaborated and the fruits supplied with assimilated matter, which would to a certainty have prevented their falling to so serious an extent, if at all.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (F. A.).—The specimen sent had no flower, but it is no doubt *Amelanchier Botryapium*. (T. K.).—Much crushed and carelessly packed, perhaps it is *Tiarella cordifolia*. (W. C.).—The numbers were not attached to the specimens, so we can only distinguish the large "Cactus" flowers as *Phyllocactus grandiflorus*, and the speckled flower as *Fritillaria Meleagris*. (F. D.).—1, *Pyrus Aucuparia*; 2, Insufficient. 3, *Prunus Padus*; 4, *Alyssum saxatile*; 5, *Solanum Capsicastrum*.

COVENT GARDEN MARKET.—MAY 14TH.
